 - increased abdominal girth – from ascites or tumour itself
 - urinary frequency
 - constipation

Low Malignant Potential (also called "Borderline") Tumours

- a subcategory or epithelial ovarian cancer (~15% of all epithelial ovarian tumours)
- pregnancy, OCP, and breastfeeding are protective factors
- tumour cells with histologically malignant characteristics arise from the ovarian surface, but do not invade ovarian stroma.
- able to metastasize, but not commonly
- treated primarily with surgery (BSO/omenta biopsy ± hysterectomy)
 - NO proven benefit of chemotherapy
- generally slow growing, excellent prognosis
 - 5 yr survival >99%
 - recurrences tend to occur late, may be associated with low grade serous carcinoma

Malignant Ovarian Tumour Prognosis

5 Year Survival	
Stage I	75-95%
Stage II	60-75%
Stage III	23-41%
Stage IV	11%

A Risk of Malignancy Incorporating CA125, Ultrasound, and Menopausal Status for the Accurate Pre-Operative Diagnosis of Ovarian Cancer

BJOG 1990;97:922-29

RMI = U x M x CA-125

Ultrasound Findings (1 pt for each)

- Multilocular cyst
- Evidence of solid areas
- Evidence of metastases
- Presence of ascites
- Bilateral lesions

U = 1 (for U/S scores of 0 or 1)

U = 4 (for U/S scores of 2-5)

Menopausal Status

- Postmenopausal: M = 4
- Pre-menopausal: M = 1

Absolute Value of CA-125 Serum Level

- For RMI >200: Gynecologic oncology referral is recommended

Table 22. Ovarian Tumours

Type	Description	Presentation	Ultrasound/Cytology	Treatment
FUNCTIONAL TUMOURS (all benign)				
Follicular Cyst	Follicle fails to rupture during ovulation	Usually asymptomatic May rupture, bleed, tort, infarct causing pain ± signs of peritoneal irritation	4-8 cm mass, unilocular, lined with granulosa cells	Symptomatic or suspicious masses warrant surgical exploration Otherwise if <6 cm, wait 6 wk then re-examine as cyst usually regresses with next cycle OCP (ovarian suppression) – will prevent development of new cysts Treatment usually laparoscopic (cystectomy vs. oophorectomy, based on fertility choice)
Corpus Luteum Cyst	Corpus luteum fails to regress after 14 d, becoming cystic or hemorrhagic	More likely to cause pain than follicular cyst May delay onset of next period	Larger (10-15 cm) and firmer than follicular cysts	Same as for follicular cysts
Theca-Lutein Cyst	Due to atretic follicles stimulated by abnormal β-hCG levels	Associated with molar pregnancy, ovulation induction with clomiphene		Conservative Cyst will regress as β-hCG levels fall
Endometrioma	See <i>Endometriosis</i> , GY13			
Polycystic Ovaries	See <i>Polycystic Ovarian Syndrome</i> , GY24			
BENIGN GERM-CELL TUMOURS				
Benign Cystic Teratoma (dermoid)	Single most common ovarian germ cell neoplasm Elements of all 3 cell lines; contains dermal appendages (sweat and sebaceous glands, hair follicles, teeth)	May rupture, twist, infarct 20% bilateral 20% occur outside of reproductive yr	Smooth-walled, mobile, unilocular Ultrasound may show calcification which is pathognomonic	Treatment usually laparoscopic cystectomy; may recur
MALIGNANT GERM-CELL TUMOURS				
General Information	Rapidly growing, 2-3% of all ovarian cancers	Usually children and young women (<30 yr)		Surgical resection (often conservative unilateral salpingo-oophorectomy ± nodes) ± chemotherapy
Dysgerminoma	Produces LDH	10% bilateral		When diagnosed at stage IA – no adjuvant treatment is indicated If diagnosed at advanced stage, very responsive to chemotherapy, therefore complete resection is not necessary for cure
Immature Teratoma	No tumour marker identified	Almost always unilateral		When diagnosed at stage IA Grade 1, no adjuvant treatment is indicated Grade 2-3: either adjuvant chemo or surgical staging If diagnosed at advanced stage: very responsive to chemotherapy, therefore complete resection is not necessary for cure
Gonadoblastoma				

Table 22. Ovarian Tumours (continued)

Type	Description	Presentation	Ultrasound/Cytology	Treatment
EPITHELIAL OVARIAN TUMOURS (malignant or borderline)				
General Information	Derived from mesothelial cells lining peritoneal cavity Classified based on histologic type 80-85% of all ovarian neoplasms (includes malignant)		Varies depending on subtype	Borderline Cystectomy vs. unilateral salpingo-oophorectomy Malignant 1. Early stage (stage I): Hysterectomy/BSO/staging (omentectomy, peritoneal biopsies, washings, pelvic and para-aortic lymphadenectomy) 2. Advanced stage: Upfront cytoreductive (debulking) followed by adjuvant chemotherapy consisting of IV carboplatin/paclitaxel vs. intraperitoneal chemotherapy (stage III) neoadjuvant chemotherapy with IV carboplatin/paclitaxel, followed by delayed debulking with further adjuvant IV chemotherapy
Serous	Most common ovarian tumour 50% of all ovarian cancers 75% of epithelial tumours 70% benign	20-30% bilateral	Lining similar to fallopian tube epithelium Often multilocular Histologically contain Psammoma bodies (calcified concentric concretions)	
EPITHELIAL OVARIAN TUMOURS (malignant or borderline)				
Mucinous	20% of epithelial tumours	Rarely complicated by Pseudomyxoma peritonei: implants seed abdominal cavity and produce large quantities of mucin	Resembles endocervical epithelium Often multilocular May reach enormous size	Poor response to chemotherapy If mucinous, remove appendix as well to rule out possible source of primary disease
SEX CORD STROMAL OVARIAN TUMOURS				
General Information				Surgical resection of tumour Chemotherapy may be used for unresectable metastatic disease
Fibroma/Thecoma (benign)	From mature fibroblasts in ovarian stroma	Non-functioning Occasionally associated with Meig's syndrome (benign ovarian tumour and ascites and pleural effusion)	Firm, smooth rounded tumour with interlacing fibrocytes	
Granulosa-Theca Cell Tumours (benign or malignant)	Can be associated with endometrial cancer Inhibin is tumour marker	Estrogen-producing → feminizing effects (precocious puberty, menorrhagia, postmenopausal bleeding)	Histologic hallmark of cancer is small groups of cells known as Call-Exner bodies	
Sertoli-Leydig Cell Tumour (benign or malignant)	Can measure elevated androgens as tumour markers	Androgen-producing → virilizing effects (hirsutism, deep voice, recession of front hairline)		
METASTATIC OVARIAN TUMOURS				
From GI Tract, Breast, Endometrium, Lymphoma	4-8% of ovarian malignancies Krukenberg tumour – metastatic ovarian tumour (usually GI tract, commonly stomach or colon, breast) with "signet-ring" cells			

Investigation of Suspicious Ovarian Mass

- women with suspected ovarian cancer based on history, physical, or investigations should be referred to a gynecologic oncologist
 - bimanual examination
 - solid, irregular, or fixed pelvic mass is suggestive of ovarian cancer
 - RMI (Risk of Malignancy Index) is best tool available to assess likelihood of ovarian malignancy and need for pre-operative gynecologic oncology referral (see sidebar, GY??)
- physical exam findings largely dependent on stage of disease
- blood work: CA-125 for baseline, CBC, liver function tests, electrolytes, creatinine
- radiology
 - transvaginal ultrasound best to visualize ovaries
 - CT abdomen and pelvis to look for metastatic disease
 - bone scan or PET scan not indicated
- try to rule out other primary source if suspected, based on:
 - occult blood per rectum: endoscopy ± barium enema
 - gastric symptoms: gastroscopy ± upper GI series
 - abnormal vaginal bleeding: endometrial biopsy to rule out concurrent endometrial cancer;
 - abnormal cervix: need to biopsy cervix (NOT pap smear) breast lesion identified or risk factors present: mammogram

Effects of Screening on Ovarian Cancer Mortality: The Prostate, Lung, Colorectal, and Ovarian Cancer Screening Randomized Controlled Trial

JAMA 2011;305:2295-2303

Objective: To evaluate the effect of screening for ovarian cancer with CA-125 and transvaginal ultrasound on mortality in the prostate, lung, ectal, and ovarian (PLCO) cancer screening trial.
Participants: 78,216 women aged 55-74 yr.

Study Groups: Intervention group – annual screening with CA-125 for 6 yr, transvaginal ultrasound for 4 yr; control group – no CA-125 or transvaginal ultrasound screening, received usual medical care.

Follow-up: Maximum 13 yr (median, 12.4 yr).

Outcome Measures: Mortality from ovarian cancer, including primary fallopian tube cancers. Secondary outcomes included ovarian cancer incidence and complications associated with screening, examinations, and diagnostic procedures.

Results: Of those diagnosed with ovarian cancer in the intervention and usual care group, the mortality was 3.1% and 2.6% respectively. 15% of women undergoing diagnostic evaluation following a false positive screening test suffered a complication of the procedure.

Conclusions: Simultaneous screening with CA-125 and transvaginal ultrasound compared with usual care did not reduce ovarian cancer mortality. Diagnostic evaluation following a false positive screening test was associated with complications.

Table 23. FIGO Staging for Primary Carcinoma of the Ovary (Surgical Staging) (2014)

Stage	Description
I	Growth limited to the ovaries
IA	1 ovary, no ascites, no tumour on external surface, capsule intact, negative washings
IB	2 ovaries, no ascites, no tumour on external surface, capsule intact
IC	1 or 2 ovaries with any of the following: surgical spill (IC1), capsule ruptured (IC2), tumour on ovarian surface (IC2), or malignant cells in ascites (IC3)
II	Growth involving one or both ovaries with pelvic extension or primary peritoneal cancer
IIA	Extension ± implants to uterus/tubes
IIB	Extension to other pelvic structures
III	Tumour involving one or both ovaries with peritoneal implants outside the pelvis and/or positive retroperitoneal nodes
IIIA	Positive retroperitoneal LNs and/or microscopic metastasis beyond pelvis
IIIA1	Positive retroperitoneal LNs
IIIA2	Microscopic, extrapelvic peritoneal involvement ± positive retroperitoneal LNs
IIB	Macroscopic peritoneal metastasis beyond pelvis ≤2 cm, ± positive retroperitoneal LNs. Includes extension to capsule of liver/spleen
IIIC	Same as above but peritoneal metastasis >2 cm
IV	Distant metastasis beyond peritoneal cavity
IVA	Pleural effusion with positive cytology
IVB	Hepatic and/or splenic parenchymal metastasis or metastasis to extra-abdominal organs (inguinal LNs and LNs outside of abdominal cavity included)

FIGO = International Federation of Gynecology and Obstetrics

Effectiveness, Safety, and Cost-Effectiveness of Primary Cytoreductive Surgery

Cochrane Database Syst Rev 2011;(8):CD007565

Summary: During primary surgery for stage III or IV epithelial ovarian cancer, all attempts should be made to achieve complete cytoreduction. When this is not achievable, optimal (<1cm) residual disease should be the goal.

Methods: Identified 11 retrospective studies consisting of 4735 women using comprehensive search strategy.

Results:

1. When suboptimal (margins >1cm) was compared with optimal (<1cm) cytoreduction, the survival estimates were reduced but remained statistically in favour of the lower volume disease group
2. No significant difference in overall survival between suboptimal and optimal cytoreduction
3. Borderline difference in progression free survival when residual disease >2cm and <2cm were compared (p=0.05)

Use of Intraperitoneal Chemotherapy for Ovarian Cancer

Cochrane Database Syst Rev 2016 12;(1):CD005340

Summary: intraperitoneal chemotherapy increases overall survival and progression-free survival from advanced ovarian cancer. Nonetheless, potential for catheter related complications need to be considered. The dose, timing, and mechanisms of administration cannot be determined. More research is required before accepting it as standard practice.

Methods: comprehensive search strategy leading to in 9 RCTs assessing women with a new diagnosis of primary epithelial ovarian cancer, of any FIGO stage, following cytoreductive surgery (n=2119). Standard IV chemotherapy was compared with chemotherapy with intraperitoneal administration components.

Results:

1. Women are less likely to die if they receive an intraperitoneal component to chemotherapy (8 studies, 2026 women; HR 0.81, CI 0.72-9.9)
2. Intraperitoneal component chemotherapy prolonged the disease-free interval (5 studies, 1311 women; HR 0.78, CI 0.7-0.86)
3. Greater serious toxicity with intraperitoneal component (GI effects, pain, fever, and infection)
Less ototoxicity with intraperitoneal component

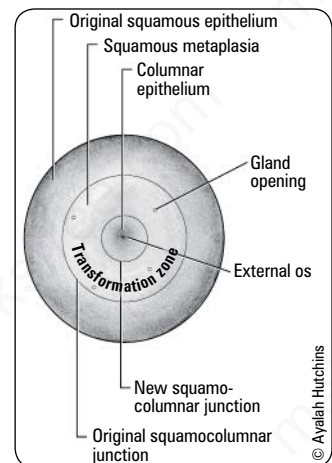

Figure 22. The cervix

Cervical cancer is most prevalent in developing countries and therefore is the only gynecologic cancer that uses clinical staging; this facilitates consistent international staging with countries that do not have technologies, such as CT and MRI

Cervix

BENIGN CERVICAL LESIONS

- Nabothian cyst/inclusion cyst
- no treatment required
- endocervical polyps
- treatment is polypectomy (office procedure)

MALIGNANT CERVICAL LESIONS

Epidemiology

- majority are SCC (70%); adenocarcinomas increasing (25%); rare subtypes include small cell, adenosquamous
- 8,000 deaths annually in North America
- annual Pap test reduces a woman's chance of dying from cervical cancer from 0.4% to 0.05%
- average age at presentation: 52 yr old

Etiology

- at birth, vagina is lined with squamous epithelium; columnar epithelium lines only the endocervix and the central area of the ectocervix (original squamocolumnar junction)
- during puberty, estrogen stimulates eversion of a single columnar layer (ectopy), thus exposing it to the acidic pH of the vagina, leading to metaplasia (change of exposed epithelium from columnar to squamous)
 - a new squamocolumnar junction forms as a result
- the transformation zone (TZ) is the area located between the original and the current squamocolumnar junction
- the majority of dysplasias and cancers arise in the TZ of the cervix
- must have active metaplasia in presence of inducing agent (HPV) to get dysplasia
- dysplasia → carcinoma *in situ* (CIS) → invasion
- slow process (~10 yr on average)
- growth is by local extension
- metastasis occurs late

Risk Factors

- HPV infection
 - see *Sexually Transmitted Infections, GY27*
 - high risk of neoplasia associated with types 16, 18
 - low risk of neoplasia associated with types 6, 11
 - >99% of cervical cancers contain one of the high risk HPV types
- high risk behaviours (risk factors for HPV infection)
 - multiple partners
 - other STIs (HSV, trichomonas)
 - early age at first intercourse
 - high risk male partner

- smoking
- poor screening uptake is the most important risk factor for cervical cancer in Canada
- at-risk groups include:
 - immigrant Canadians
 - First Nations Canadians
 - geographically isolated Canadians
 - sex-trade workers
 - low socioeconomic status

Cervical Cancer Screening Guidelines (Pap Test)

- see [Family Medicine, FM5](#)

Clinical Features

- SCC: exophytic, fungating tumour
- adenocarcinoma: endophytic, with barrel-shaped cervix
- early
 - asymptomatic
 - discharge: initially watery, becoming brown or red
 - postcoital bleeding
- late
 - 80-90% present with bleeding: either postcoital, postmenopausal or irregular bleeding
 - pelvic or back pain (extension of tumour to pelvic walls)
 - bladder/bowel symptoms
- signs
 - friable, raised, reddened, or ulcerated area visible on cervix

The Bethesda Classification System is based on cytological results of a Pap test that permits the examination of cells but not tissue structure. Cervical intraepithelial neoplasia (CIN) or cervical carcinoma is a histological diagnosis, requiring a tissue sample via biopsy of suspicious lesions seen during colposcopy

With development of hypertension early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease

CA-125 is indicated for monitoring response to treatment

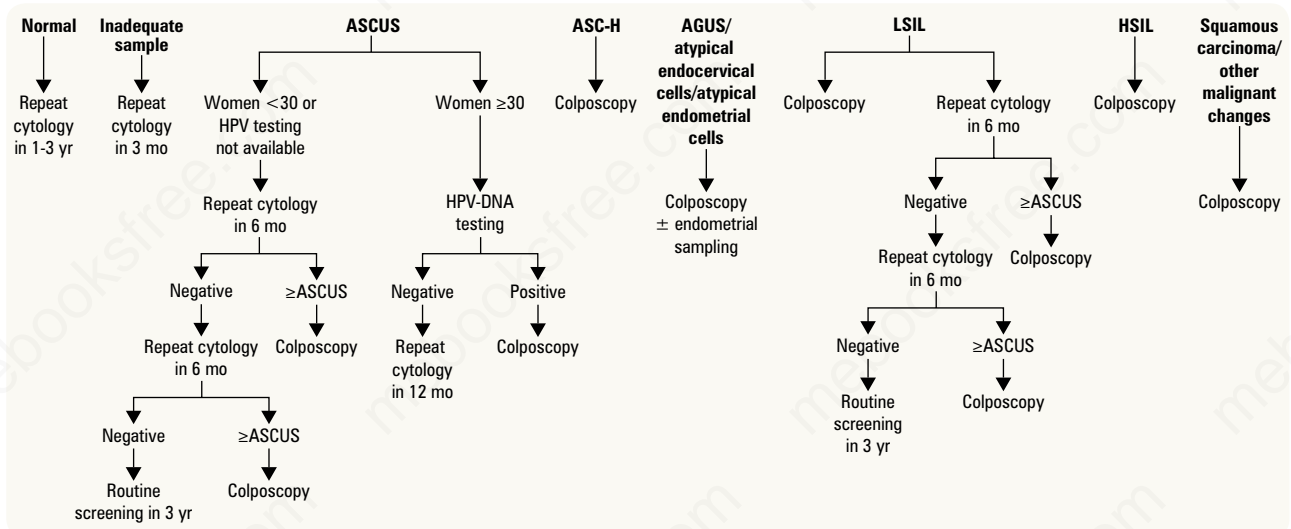

Figure 23. Decision making chart for Pap test (not applicable for adolescents)

Adapted from: Ontario Cervical Screening Practice Guidelines. May 2012. Cervical screening guidelines unique to each province

Diagnosis

- colposcopy is a clinical procedure that facilitates identification and biopsy of suspicious cells
- in colposcopy:
 - apply acetic acid and identify acetowhite lesions, punctuation, mosaicism, and abnormal blood vessels to guide cervical biopsy
 - endocervical curettage (ECC) if entire lesion is not visible or no lesion visible
 - diagnostic excision (LEEP) if:
 - ♦ unsatisfactory colposcopy (poor visualization/access to transformation zone)
 - ♦ discrepancy between cytology, colposcopy, and histological findings
 - ♦ positive findings/glandular abnormalities in endocervical curettage
 - ♦ suspicious for adenocarcinoma in situ (consider cold-knife conization)
 - ♦ recurrence of lesion post-ablation or excision
 - ♦ inability to rule out invasive disease, i.e. large lesions (lesions extending into endocervical canal, extending widely on cervix, or onto vaginal epithelium)
- consider cold knife conization (in OR) if glandular abnormality suspected based on cytology or colposcopic findings due to concern for margin interpretation
- tests permitted for FIGO clinical staging include: physical exam (including examination under anesthesia), cervical biopsy (including cone biopsy), proctoscopy/cystoscopy, IVP, ultrasound liver/kidneys, CXR, LFTs
- MRI and/or CT and/or PET scan often done to facilitate planning of radiation therapy, results do not influence clinical stage

Causes of Elevated CA-125

- Age influences reliability of test as a tumour marker
- 50% sensitivity in early stage ovarian cancer (poor) – therefore not good for screening

Malignant

- Gyne: ovary, uterus
- Non-Gyne: pancreas, stomach, colon, rectum

Non-Malignant

- Gyne: benign ovarian neoplasm, endometriosis, pregnancy, fibroids, PID
- Non-Gyne: cirrhosis, pancreatitis, renal failure

Table 24. FIGO Staging Classification of Cervical Cancer (Clinical Staging) (2009)

Stage	Description
I	Confined to cervix
IA	Microinvasive (diagnosed only by microscopy)
IA1	Stromal invasion not >3 mm deep, not >7 mm wide
IA2	3-5 mm deep; not >7 mm wide
IB	Clinically visible lesion confined to cervix, or microscopic lesion >IA
IB1	Clinically visible lesion ≤4 mm in greatest dimension
IB2	Clinically visible lesion >4 mm in greatest dimension
II	Beyond uterus but not to the pelvic wall or lower 1/3 of vagina
IIA	No obvious parametrial involvement
IIA1	Clinically visible lesion ≤4 mm in greatest dimension
IIA2	Clinically visible lesion >4 mm in greatest dimension
IIB	Obvious parametrial involvement
III	Extends to pelvic wall, and/or involves lower 1/3 of vagina and/or causes hydronephrosis or non-functioning kidney
IIIA	Involves lower 1/3 vagina but no extension into pelvic side wall
IIIB	Extension into pelvic side wall and/or hydronephrosis or non-functioning kidney
IV	Carcinoma has extended beyond true pelvis or has involved (biopsy proven) the mucosa of the bladder or rectum
IVA	Spread of the growth to adjacent organs (bladder or rectum)
IVB	Distant metastases

Treatment: Prevention and Management

Prevention: HPV Vaccine

- two vaccines currently approved (Gardasil®, Cervarix®)

Table 25. Comparison of Two Vaccines against Human Papillomavirus (HPV)

	Gardasil®*	Cervarix®
Viral Strains Covered	6, 11, 16, 18	16, 18
Route of Administration	IM	IM
Schedule of Dosing	0, 2, 6 mo	0, 1, 6 mo
Side Effects	Local: redness, pain, swelling General: headache, low grade fever, GI upset	Local: redness, pain, swelling General: headache, low grade fever, GI upset
Approved Age	Females age 9-45, males age 9-26	Females age 10-25
Contraindications	Pregnant women and women who are nursing (limited data)	

*Gardasil-9 also covers types 31, 33, 45, 52, and 58; also used to prevent genital warts

- should be administered before onset of sexual activity (i.e. before exposure to virus) for optimal benefit of vaccination
- may be given at the same time as hepatitis B or other vaccines using a different injection site
- not for treatment of active infections
- most women will not be infected with all four types of the virus at the same time, therefore vaccine is still indicated for sexually active females or those with a history of previous HPV infection or HPV-related disease
- conception should be avoided until 30 d after last dose of vaccination

Cervical Cancer Prognosis 5-yr Survival

Stage 0	99%
Stage I	75%
Stage II	55%
Stage III	30%
Stage IV	7%
Overall	50-60%

Efficacy of Human Papillomavirus (HPV)-16/18 AS04-Adjuvanted Vaccine Against Cervical Infection and Precancer Caused by Oncogenic HPV Types (PATRICIA): Final Analysis of a Double-Blind, Randomized Study in Young Women

Lancet 2009;374:301-14

Study: Phase III double-blind, controlled RCT.

Patients: 18,644 women aged 15-25.

Selected Outcomes: Development of HPV-16/18 associated CIN II+ was the primary outcome. Secondary to this were persistence of infections with HPV-16, HPV-18, or other oncogenic HPV types.

Selected Results: Efficacy against development of HPV-16/18 associated CIN II+ was 98.1% (p<0.0001). High levels of cross-protection were observed for persistent infection with HPV-31 and HPV-45 and HPV-31 or HPV-45 associated CIN II+.

Conclusions: The HPV-16/18 AS04-adjuvanted vaccine protected against HPV-16/18 associated CIN II+ lesions and lesions associated with HPV-31, HPV-33, and HPV-45.

Table 26. Management of Patients Abnormal Cervical Histology and Cervical Cancer

Management	
CIN I	Preferred option for biopsy-proven CIN I is observation Repeat assessment and cytology in 12 mo Management according to cytology results If after HSIL or AGC: Cytology and histology should be reviewed If discrepancy remains, excisional biopsy may be considered
CIN II and CIN III	Women ≥ 25 yr: CIN II or III should be treated Excisional procedures preferred for CIN III Those with positive margins should have follow-up with colposcopy and directed biopsies and/or endocervical curettage Women <25 yr: Same treatment for CIN II and CIN III: observe with colposcopy at 6-mo intervals for up to 24 mo before treatment considered During pregnancy: CIN II or III suspected or diagnosed during pregnancy, repeat colposcopy and treatment delayed until 8-12 wk after delivery
Stage IA1 (no LVSI)	LEEP if future fertility desired (and lesion ≤ 2 cm) Simple hysterectomy if future fertility is not desired
Stage IA2, IB1	Typically treated with radical hysterectomy and pelvic lymphadenectomy (sentinel nodes under study) If high chance of adjuvant radiation then consider primary chemoradiation as more morbidity occurs from double modality treatment (surgery and radiation) Equal cure rates may be obtained with primary radiation therapy; advantage of surgery: may accurately stage and grade and more targeted adjuvant therapy Advantage is that ovaries can be spared if pre-menopausal For fertility preservation (if tumour < 2cm), may have radical trachelectomy (removal of cervix and parametria) and nodes instead of radical hysterectomy for early-stage disease chemoradiation therapy if adverse high risk prognostic factors on radical surgical specimen, such as: positive pelvic lymph nodes, positive parametria, and/or positive margins or adverse cervical factors (2 or more): deep stromal invasion, size >4 cm, LVSI
Stages IB2 (>4 cm), II, III, IV	Primary chemoradiation therapy CT assess extent of disease: evaluate pelvic and para-aortic nodes For positive nodes on PET: primary chemoradiation with extended field RT Hysterectomy generally not suggested following primary treatment with curative intent

Abnormal Pap Tests in Pregnancy

- incidence: 1/2,200
- Pap test at all initial prenatal visits
 - if abnormal Pap or suspicious lesion, refer to colposcopy
 - if diagnostic conization required, should be deferred until second trimester (T2) to minimize risk of pregnancy loss
 - if invasive cancer ruled out, management of dysplasia deferred until completion of pregnancy (may deliver vaginally)
 - if invasive cancer present, management depends on prognostic factors, degree of fetal maturity, and patient wishes
 - general recommendations in T1: consider pregnancy termination, management with either radical surgery (hysterectomy vs. trachelectomy if desires future fertility), or concurrent chemoradiation therapy
 - recommendations in T2/T3: delay of therapy until viable fetus and C/S for delivery with concurrent radical surgery or subsequent concurrent chemoradiation therapy

Vulva**BENIGN VULVAR LESIONS****Non-Neoplastic Disorders of Vulvar Epithelium**

- biopsy is necessary to make diagnosis and/or rule out malignancy
- hyperplastic dystrophy (squamous cell hyperplasia)
 - surface thickened and hyperkeratotic
 - pruritus most common symptom
 - typically postmenopausal women
 - treatment: 1% fluorinated corticosteroid ointment bid for 6 wk
- lichen sclerosis
 - subepithelial fat becomes diminished; labia become thin, atrophic, with membrane-like epithelium and labial fusion
 - pruritus, dyspareunia, burning
 - 'figure of 8' distribution
 - most common in postmenopausal women but can occur at any age
 - treatment: ultrapotent topical steroid 0.05% clobetasol x 2-4 wk then taper down, can consider long term suppression twice a week
- mixed dystrophy (lichen sclerosis with epithelial hyperplasia)
 - hyperkeratotic areas with areas of thin, shiny epithelium
 - treatment: fluorinated corticosteroid ointment

Tumours

- papillary hidradenoma, nevus, fibroma, hemangioma

MALIGNANT VULVAR LESIONS**Epidemiology**

- 5% of genital tract malignancies
- 90% SCC; remainder melanomas, basal cell carcinoma, Paget's disease, Bartholin's gland carcinoma
 - Type I disease: HPV-related (50-70%)
 - ♦ more likely in younger women
 - ♦ 90% of vulvar intraepithelial neoplasia (VIN) contain HPV DNA (usually types 16, 18)
 - Type II disease: not HPV-related, associated with current or previous vulvar dystrophy
 - ♦ usually postmenopausal women

Risk Factors

- HPV infection
- VIN: precancerous change which presents as multicentric white or pigmented plaques on vulva (may only be visible at colposcopy)
 - progression to cancer rarely occurs with appropriate management
 - treatment: local excision (i.e. superficial vulvectomy ± split thickness skin grafting to cover defects if required) vs. ablative therapy (i.e. laser, cauterization) vs. local immunotherapy (imiquimod)

Clinical Features

- many patients asymptomatic at diagnosis (many also deny or minimize symptoms)
- most lesions occur on the labia majora, followed by the labia minora (less commonly on the clitoris or perineum)
- localized pruritus or lesion most common
- less common: raised red, white or pigmented plaque, ulcer, bleeding, discharge, pain, dysuria
- patterns of spread
 - local
 - groin lymph nodes (usually inguinal → pelvic nodes)
 - hematogenous

Investigations

- ± colposcopy
- ALWAYS biopsy any suspicious lesion
 - do not remove entire lesion so if malignant, site can be identified for sentinel LN injection

Prognosis

- depends on stage – particularly nodal involvement (single most important predictor followed by tumour size)
- lesions >4 cm associated with poorer prognosis
- overall 5 yr survival rate: 79%

Treatment

- T1 lesions (tumour confined to vulva; no extension to adjacent perineal structures): Radical local excision
- T2 lesions (tumour of any size with extension to adjacent perineal structures): modified radical vulvectomy
- T3 lesions (extension to any of: proximal 2/3 of urethra, proximal 2/3 of the vagina, bladder
 - mucosa, rectal mucosa or fixed to pelvic bone): chemoradiation followed by selective resection of residual primary
- node positive disease: adjuvant chemoradiation or radiation therapy

Any suspicious lesion of the vulva should be biopsied

Vagina**BENIGN VAGINAL LESIONS**

- inclusion cysts
 - cysts form at site of abnormal healing of laceration (e.g. episiotomy)
 - no treatment required
- endometriosis
 - dark lesions that tend to bleed at time of menses
 - treatment: excision
- Gartner's duct cysts
 - remnants of Wolffian duct, seen along side of cervix
 - treatment: conservative unless symptomatic
- urethral diverticulum
 - can lead to recurrent urethral infection, dyspareunia
 - treatment: surgical correction if symptomatic

MALIGNANT VAGINAL LESIONS

Epidemiology

- primary carcinomas of the vagina represent 2-3% of malignant neoplasms of the female genital tract
- 80-90% are SCC
- more than 50% diagnosed between 70-90 yr old

Risk Factors

- associated with HPV infection (analogous to cervical cancer)
- increased incidence in patients with prior history of cervical and vulvar cancer

Investigations

- cytology
 - significant false negative rate for existing malignancy (i.e. if gross lesion present, biopsy!)
- colposcopy
- Schiller test (normal squamous epithelium takes up Lugol's iodine)
- biopsy, partial vaginectomy (wide local excision for diagnosis)
- rule out disease on cervix, vulva, or anus (most vaginal cancers are actually metastatic from one of these sites)
- staging

Clinical Features

Table 27. Clinical Features of Malignant Vaginal Lesions

Type	Clinical Features
Vaginal Intra-Epithelial Neoplasia (VAIN)	Grades: analogous to cervical dysplasia
Squamous Cell Carcinoma (SCC)	Most common site is upper 1/3 of posterior wall of vagina Asymptomatic Painless discharge and bleeding Vaginal discharge (often foul-smelling) Vaginal bleeding especially during/post-coitus Urinary and/or rectal symptom 2° to compression
Adenocarcinoma	Most are metastatic, usually from cervix, endometrium, ovary, or colon Most primaries are clear cell adenocarcinomas 2 types: non-DES and DES syndrome

Treatment

- Stage I
 - radiation therapy: for tumours >2 cm diameter or tumour involvement of the mid to lower vagina
 - surgical excision: radical hysterectomy, upper vaginectomy and bilateral pelvic lymphadenectomy
- Stage II - IV: chemoradiation

Fallopian Tube

- least common site for carcinoma of female reproductive system (0.3%)
- usually serous epithelial carcinoma
- new evidence shows that some serous ovarian cancers originate in the fallopian tube
- more common in fifth and sixth decade

Clinical Features

- classic triad present in minority of cases, but very specific
 - watery discharge (most specific) = "hydrops tubae profluens"
 - vaginal bleeding or discharge in 50% of patients
 - crampy lower abdominal/pelvic pain
 - most patients present with a pelvic mass (see *Ovarian Tumours*, GY40 for guidelines regarding diagnosis/investigation)

Treatment

- as for malignant epithelial ovarian tumours

Gestational Trophoblastic Disease/Neoplasia

- refers to a spectrum of proliferative abnormalities of the trophoblast

Epidemiology

- 1/1,000 pregnancies
- marked geographic variation – as high as 1/125 in Taiwan
- 80% benign, 15% locally invasive, 5% metastatic
- cure rate >95%

HYDATIDIFORM MOLE (Benign GTD)

Complete Mole

- most common type of hydatidiform mole
- diffuse trophoblastic hyperplasia, hydropic swelling of chorionic villi, no fetal tissues, or membranes present
- 46XX or 46XY, chromosomes completely of paternal origin (90%)
- 2 sperm fertilize empty egg or 1 sperm with reduplication
- 15-20% risk of progression to malignant sequelae
- risk factors
 - geographic (South East Asia most common)
 - others (maternal age >40 yr, β -carotene deficiency, vitamin A deficiency) – not proven
- clinical features
 - often present during apparent pregnancy with abnormal symptoms/findings
 - vaginal bleeding (97%)
 - excessive uterine size for LMP (51%)
 - theca-lutein cysts >6 cm (50%)
 - preeclampsia (27%)
 - hyperemesis gravidarum (26%)
 - hyperthyroidism (7%)
 - β -hCG >100,000 IU/L
 - no fetal heart beat detected

With development of hypertension early in pregnancy (i.e. <20 wk), think gestational trophoblastic disease

Partial (or Incomplete) Mole

- focal trophoblastic hyperplasia and hydropic villi are associated with fetus or fetal parts
- often triploid (XXY, XYY, XXX) with chromosome complement from both parents
 - usually related to single ovum fertilized by two sperm
- low risk of progression to malignant sequelae (<4%)
- associated with fetus, which may be growth-restricted, and/or have multiple congenital malformations
- clinical features
 - typically present similar to threatened/spontaneous/missed abortion
 - pathological diagnosis often made after D&C

Investigations

- quantitative β -hCG levels (tumour marker) abnormally high for gestational age
- U/S findings
 - if complete: no fetus (classic “snow storm” due to swelling of villi)
 - if partial: molar degeneration of placenta \pm fetal anomalies, multiple echogenic regions corresponding to hydropic villi, and focal intrauterine hemorrhage
- CXR (may show metastatic lesions)
- features of molar pregnancies at high risk of developing persistent GTN post-evacuation
 - local uterine invasion as high as 31%
 - β -hCG >100,000 IU/L
 - excessive uterine size
 - prominent theca-lutein cysts

Treatment

- suction D&C with sharp curettage and oxytocin
- Rhogam[®] if Rh negative
- consider hysterectomy (if patient no longer desires fertility)
- prophylactic chemotherapy of no proven benefit
- chemotherapy for GTN if develops after evacuation

Follow-Up

- contraception required to avoid pregnancy during entire follow-up period
- serial β -hCGs (as tumour marker) every week until negative x 3 (usually takes several wk), then monthly for 6-12 mo prior to trying to conceive again
- increase or plateau of β -hCG indicates GTN \rightarrow patient needs chemotherapy

GTN (MALIGNANT GTD)

Invasive Mole or Persistent GTN

- diagnosis made by rising or plateau in β -hCG, development of metastases following treatment of documented molar pregnancy
- histology: molar tissue from D&C
- metastases are rare (4%)

Choriocarcinoma

- often present with symptoms from metastases
- highly anaplastic, highly vascular
- no chorionic villi, elements of syncytiotrophoblast and cytotrophoblast
- may follow molar pregnancy, abortion, ectopic, or normal pregnancy

Placental-Site Trophoblastic Tumour

- rare aggressive form of GTN
- abnormal growth of intermediate trophoblastic cells
- low β -hCG, production of human placental lactogen (hPL), relatively insensitive to chemotherapy

CLASSIFICATION of GTN

- non-metastatic
 - ~15% of patients after molar evacuation
 - may present with abnormal bleeding
 - all have rising or plateau of β -hCG
 - negative metastases on staging investigations
- metastatic
 - 4% patients after treatment of complete molar pregnancy
 - metastasis more common with choriocarcinoma which tends toward early vascular invasion and widespread dissemination
 - if signs or symptoms suggest hematogenous spread, do not biopsy (they bleed)
 - ◆ lungs (80%): cough, hemoptysis, CXR lesion(s)
 - ◆ vagina (30%): vaginal bleeding, "blue lesions" on speculum exam
 - ◆ pelvis (20%): rectal bleeding (if invades bowel), U/S lesion(s)
 - ◆ liver (10%): elevated LFTs, U/S or CT findings
 - ◆ brain (10%): headaches, dizziness, seizure (symptoms of space-occupying lesion), CT/MRI findings
 - highly vascular tumour \rightarrow bleeding \rightarrow anemia
 - all have rising or plateau of β -hCG
 - classification of metastatic GTN
 - ◆ divided into good prognosis and bad prognosis
 - ◆ features of bad prognosis
 - long duration (>4 mo from antecedent pregnancy)
 - high pre-treatment β -hCG titre: >100,000 IU/24 h urine or >40,000 IU/L of blood
 - brain or liver metastases
 - prior chemotherapy
 - metastatic disease following term pregnancy
 - ◆ good prognosis characterized by the absence of each of these features

Lungs are #1 site for malignant GTN metastases; when pelvic exam and chest x-ray are negative, metastases are uncommon

Investigations – For Staging

- blood work: CBC, electrolytes, creatinine, β -hCG, TSH, LFTs
- imaging: CXR, U/S pelvis, CT abdo/pelvis, CT brain
- if suspect brain metastasis but CT brain negative, consider lumbar puncture for CSF β -hCG
- ratio of plasma β -hCG:CSF β -hCG <60 indicates metastases

Table 28. FIGO Staging and Management of Malignant GTN

Stage	Findings	Management
I	Disease confined to uterine corpus	Single agent chemotherapy for low risk disease (WHO score ≤ 6) 1st line: pulsed – actinomycin D (Act-D) IV q2wk Alternatives: MTX-based regimen 20% of patients need to switch to alternate single-agent regimen due to failure of β -hCG to return to normal Combination chemotherapy (EMA-CO: etoposide, MTX, ACT-D, cyclophosphamide, vincristine) if high risk (WHO score ≥ 7) or if resistant to single agent chemotherapy Can consider hysterectomy if fertility not desired or placental-site trophoblastic tumour
II	Metastatic disease to genital structures	As above
III	Metastatic disease to lungs with or without genital tract involvement	As above
IV	Distant metastatic sites including brain, liver, kidney, GI tract	Usually high risk (EMA-CO) with surgical resection of sites of disease Persistence/resistance to chemotherapy Consider radiation for brain mets

Table 29. WHO Prognostic Score for GTD (2011)

Prognostic Factor	Score			
	0	1	2	4
Maternal Age	>40	40		
Antecedent Pregnancy	Mole	Abortion	Term	
Interval (end of Antecedent Pregnancy to chemotherapy in months)	<4	4-6	7-13	>13
HCG IU/l	<103	103-104	104-105	>105
Number of Metastases	0	1-4	5-8	>8
Site of Metastases	Lung	Spleen, kidney	GI tract	Brain, liver
Largest Tumour Mass		3-5 cm	>5 cm	
Prior Chemotherapy			Single drug	Two drug

Follow-up (for GTN)

- contraception for all stages to avoid pregnancy during entire follow-up period
- stage I, II, III
 - weekly β -hCG until 3 consecutive normal results
 - then monthly x 12 mo
- stage IV
 - weekly β -hCG until 3 consecutive normal results
 - then monthly x 24 mo

GTN Diagnosis

- β -hCG plateau: <10% drop in β -hCG over four values in 3 wk (e.g. days 1, 7, 14, and 21) OR
- β -hCG rise >20% in any two values over two wk or longer (e.g. measure at days 1, 7, 14) OR
- β -hCG persistently elevated >6 mo OR
- metastases on workup

Common Medications

Table 30. Common Medications

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
acyclovir (Zovirax®)	Antiviral; inhibits DNA synthesis and viral replication	First Episode: 400 mg PO tid x 7-10 d Recurrence: 400 mg PO tid x 5 d	Genital herpes	S/E: headache, GI upset D/I: zidovudine, probenecid
bromocriptine (Parlodel®)	Dopaminomimetic Agonist at D2R Antagonist at D1R Acts directly on anterior pituitary cells to inhibit synthesis and release of prolactin	Initial: 1.25-2.5 mg PO qhs with food Then: increase by 2.5 mg every 2-7 d as needed until optimal therapeutic response Usual Range: 1.5-15 mg OD For IVF: Initial: 1.25 mg/d PO between days 4-6 of follicular phase Then: 2.5 mg/d until 3 d after onset menstruation	Galactorrhea + amenorrhea 2° to hyperprolactinemia Prolactin-dependent menstrual disorders and infertility Prolactin-secreting adenomas (microadenomas, prior to surgery of macroadenomas) IVF	S/E: N/V, headache, postural hypotension, somnolence C/I: uncontrolled HTN, pregnancy-induced HTN, CAD, breastfeeding D/I: domperidone, macrolides, octreotide
clomiphene citrate (Clomid®)	Increases output of pituitary gonadotropins which induces ovulation	50 mg OD x 5 d Try 100 mg or 160 mg OD if ineffective 3 courses = adequate trial	Patients with persistent ovulatory dysfunction (e.g. amenorrhea, PCOS) who desire pregnancy	S/E: Common – hot flashes, abdominal discomfort, exaggerated cyclic ovarian enlargement, accentuation of Mittelschmerz Rare – ovarian hyperstimulation syndrome, multiple pregnancy, visual blurring, birth defects C/I: pregnancy, liver disease, hormone-dependent tumours, ovarian cyst, undiagnosed vaginal bleeding
clotrimazole (Canesten®)	Antifungal; disrupt fungal cell membrane	Tablet: 100 mg/d intravaginally x 7 d or 200 mg/d x 3 d or 500 mg x 1 dose Cream (1 or 2%): 1 applicator intravaginally qhs x 3-7 d Topical: apply bid x 7 d	Vulvovaginal candidiasis	S/E: vulvar/vaginal burning
danazol (Cyclomen® – CAN) (Danocrine® – US)	Synthetic steroid that inhibits pituitary gonadotropin output and ovarian steroid synthesis Has mild androgenic properties	200-800 mg in 2-3 divided doses Used for 3-6 mo Biannual hepatic U/S required if >6 mo use	Endometriosis 1° menorrhagia/DUB	S/E: weight gain, acne, mild hirsutism, hepatic dysfunction C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding, severely impaired renal/hepatic/cardiac function, porphyria, genital neoplasia, thromboembolic disease D/I: warfarin, carbamazepine, cyclosporine, tacrolimus, anti-hypertensives

Table 30. Common Medications (continued)

Drug Name (Brand Name)	Action	Dosing Schedule	Indications	Side Effects (S/E), Contraindications (C/I), Drug Interactions (D/I)
doxycycline	Tetracycline derivative; inhibit protein synthesis	100 mg PO bid x ≥7 d	Chlamydia, gonococcal infection, syphilis	S/E: GI upset, hepatotoxicity C/I: pregnancy, severe hepatic dysfunction D/I: warfarin, digoxin
fluconazole (Diflucan®)	Antifungal; disrupt fungal cell membrane	150 mg PO x 1 dose	Vulvovaginal candidiasis unresponsive to clotrimazole	S/E: headache, rash, N/V, abdominal pain, diarrhea D/I: terfenadine, cisapride, astemizole, hydrochlorothiazide, phenytoin, warfarin, rifampin
leuprolide (Lupron®)	Synthetic GnRH analog Induces reversible hypoestrogenic state	3.75 mg IM q1mo or 11.25 mg IM q3mo Usually ≤6 mo, check bone density if >6 mo Retreatment with Lupron® alone not recommended because of effects on bone density	Endometriosis Leiomyomata DUB Precocious puberty	S/E: hot flashes, sweats, headache, vaginitis, reduction in bone density, acne, GI upset C/I: pregnancy, undiagnosed vaginal bleeding, breastfeeding
menotropin (Pergonal®)	Human gonadotropin with FSH and LH effects; induce ovulation and stimulate ovarian follicle development	75-150 U of FSH and LH IM OD x 7-12 d, then 10,000 U HCG one day after last dose	Infertility	S/E: bloating, irritation at injection site, abdominal/pelvic pain, headache, N/V, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, undiagnosed uterine bleeding
metronidazole (Flagyl®)	Bactericidal; forms toxic metabolites which damage bacterial DNA	2 g PO x 1 dose or 500 mg PO bid x 7 d	Bacterial vaginosis, trichomonas vaginitis	S/E: headache, dizziness, N/V, diarrhea, disulfiram-like reaction (flushing, tachycardia, N/V) C/I: pregnancy (1st trimester) D/I: cisapride, warfarin, cimetidine, lithium, alcohol, amiodarone, milk thistle, carbamazepine
oxybutinin (Ditropan®)	Anticholinergic – relaxes bladder smooth muscle, inhibits involuntary detrusor contraction	5 or 10 mg/d PO May increase doses by 5 mg weekly to a max of 30 mg/d	Overactive bladder (urge incontinence)	S/E: dry mouth/eyes, constipation, palpitations, urinary retention, dizziness, headache C/I: glaucoma, GI ileus, severe colitis, obstructive uropathy, use with caution if impaired hepatic/renal function
tolterodine (Detrol®)	Anticholinergic	1-2 mg PO bid	Overactive bladder (urge incontinence)	S/E: anaphylaxis, psychosis, tachycardia, dry mouth/eyes, headache, constipation, urinary retention, chest pain, abdominal pain C/I: glaucoma, gastric/urinary retention, use with caution if impaired hepatic/renal function
tranexamic acid (Cyklokapron®)	Anti-fibrinolytic, reversibly inhibits plasminogen activation	1-1.5 g tid-qid for first 4 d of cycle Max 4 g/d Ophthalmic check if used for several wk	Menorrhagia	S/E: N/V, diarrhea, dizziness, rare cases of thrombosis, abdominal pain, MSK pain C/I: thromboembolic disease, acquired disturbances of colour vision, subarachnoid hemorrhage, age <15 yr
ulipristal acetate (Fibristal®)	Selective progesterone receptor modulator (SPRM)	5 mg PO OD for max 3 mo; first tablet taken anytime during first 7 days of menstruation	Leiomyoma (pre-operative)	S/E: headache, hot flushes, constipation, vertigo, endometrial thickening C/I: pregnancy, undiagnosed vaginal bleeding, any gynecancer
urofollitropin (Metrodin®)	FSH	75 U/d SC x 7-12d	Ovulation induction in PCOS	S/E: ovarian enlargement or cysts, edema and pain at injection site, arterial thromboembolism, fever, abdominal pain, headache, multiple pregnancy C/I: primary ovarian failure, intracranial lesion (e.g. pituitary tumour), uncontrolled thyroid/adrenal dysfunction, ovarian cyst (not PCOS), pregnancy, abnormal uterine bleeding
combined oral contraceptive pill (OCP)	Ovulatory suppression by inhibiting LH and FSH Decidualization of endometrium Thickening of cervical mucus to prevent sperm penetration		Contraception Disorders of menstruation	See Tables 8-12
intrauterine device (IUD) copper IUD (Nova-T®) progesterone-releasing IUD (Mirena®, Jaydess®)	Copper IUD: mild foreign body reaction in endometrium which is toxic to sperm and alters sperm motility Progesterone-releasing IUD: decidualization of endometrium and thickening of cervical mucus, may suppress ovulation	Contraceptive effects last 3 yrs (Jaydess®); up to 5 yr (Copper IUD, Mirena®)	Same as above	See Table 8-12

EPO	erythropoietin	MGUS	monoclonal gammopathy of unknown significance	TIBC	total iron binding capacity
ESR	erythrocyte sedimentation rate	MM	multiple myeloma	TPO	thrombopoietin
ET	essential thrombocythemia	MPN	myeloproliferative neoplasm	TTP	thrombotic thrombocytopenic purpura
FNA	fine needle aspiration	MPV	mean platelet volume	UFH	unfractionated heparin
G6PD	glucose-6-phosphate dehydrogenase	MUGA	multi-gated acquisition	UPEP	urine protein electrophoresis
G-CSF	granulocyte-colony stimulating factor	NHL	non-Hodgkin lymphoma	VTE	venous thromboembolism
GSH	glutathione	PCC	prothrombin complex concentrates	vWD	von Willebrand disease
HA	hemolytic anemia	Ph	Philadelphia chromosome	vWF	von Willebrand factor
Hb	hemoglobin	PK	prekallikrein	WBC	white blood cell
Hct	hematocrit			WHO	World Health Organization

Basics of Hematology

Erythrocyte: carries oxygen from lungs to peripheral tissues

Reticulocyte: immature erythrocyte

Neutrophil: granulocyte integral in innate immunity; main cell in acute inflammation

Eosinophil: involved in response to parasites (especially helminths) and allergic response

Basophil: granulocyte mainly involved in allergy and parasitic infection

Lymphocyte: integral cell in adaptive immunity

Monocyte: involved in innate immunity; can differentiate into macrophage or dendritic cell

Platelet: mediator of primary hemostasis

Plasma: liquid component of blood containing water, proteins, coagulation factors, and immunoglobulins

Serum: equivalent to plasma minus clotting factors and fibrinogen

Figure 1. Hematopoiesis

- over 10^{11} blood cells are produced daily
- sites of hematopoiesis in adults: pelvis, sternum, vertebral bodies, cranium
- lifespan of mature cells in blood
 - erythrocytes (90-120 d), neutrophils (~1 d), platelets (7-10 d), lymphocytes (varies – memory cells persist for years)
- role of lymphoid organs
 - spleen: part of reticuloendothelial system, sequesters aged RBCs, removes opsonized cells, site of antibody production
 - thymus: site of T-cell maturation, involutes with age
 - lymph nodes: sites of B and T-cell activation (adaptive immune response)

Complete Blood Count

Table 1. Common Terms Found in the CBC

Test	Definition	Normal Values*
Red Blood Cell (RBC) Count	The number of RBCs per volume of blood	4.2-6.9 x 10 ⁶ /mm ³
Hemoglobin (Hb)	Amount of oxygen-carrying protein in the blood	130-180 g/L (male) 120-160 g/L (female)
Hematocrit (Hct)	Percentage of a given volume of whole blood occupied by packed RBCs	45%-62% (male) 37%-48% (female)
Mean Corpuscular Volume (MCV)	Measurement of RBC size	80-100 μm^3
Mean Corpuscular Hb (MCH)	Amount of oxygen-carrying Hb inside RBCs	27-32 pg/cell
Concentration (MCHC)	Average concentration of Hb inside RBCs	32%-36%
RBC Distribution Width (RDW)	Measurement of variance in RBC size	11.0%-15.0%
White Blood Cell (WBC) Count	The number of WBCs per volume of blood	4.3-10.8 x 10 ⁹ /mm ³
WBC Differential	Neutrophils Lymphocytes Monocytes Eosinophils Basophils	1.8-7.8 x 10 ³ /mm ³ 0.7-4.5 x 10 ³ /mm ³ 0.1-1.0 x 10 ³ /mm ³ 0.0-0.4 x 10 ³ /mm ³ 0.0-0.2 x 10 ³ /mm ³
Platelet Count	The number of platelets per volume of blood	150-400 x 10 ⁹ /mm ³
Mean Platelet Volume (MPV)	Measurement of platelet size	7.2-11.7 fL
Reticulocytes	Immature RBCs that contain no nucleus but have residual RNA	Normally make up 1% of total RBC count

*Normal values may vary depending on site and age

To estimate Hb based on the Hct, multiply by 3.3

Clinical Use of RDW

- To distinguish the etiologies of microcytosis:
- Iron deficiency: increased RDW (anisocytosis) as cells are of varying sizes in iron deficiency
 - Thalassemia minor: normal RDW (also expect a high RBC count) as cells are of similar size due to genetic defect in Hb

Approach to Interpreting a CBC

- consider values in the context of individual's baseline:
 - up to 5% of population without disease may have values outside "normal" range
 - an individual may display a clinically significant change from their baseline without violating "normal" reference range
- is one cell line affected or are several?
 - if all lines are low: pancytopenia (see *Pancytopenia, H8*)
 - if RBCs and platelets are low: consider a MAHA/TMA (see *Microangiopathic Hemolytic Anemia/Thrombotic Microangiopathy, H22*)
 - if single cell line affected: see *Common Presenting Problems, H6*

Blood Film Interpretation

RED BLOOD CELLS

Size

- microcytic (MCV <80 μm^3), normocytic (MCV = 80-100 μm^3), macrocytic (MCV >100 μm^3)
- anisocytosis: RBCs with increased variability in size (increased RDW)
 - iron deficiency anemia, hemolytic anemias, myelofibrosis, blood transfusion, MDS

Colour

- hypochromic: increase in size of central pallor (normal = less than 1/3 of RBC diameter)
 - iron deficiency anemia, anemia of chronic disease, sideroblastic anemia
- polychromasia: increased reticulocytes (pinkish-blue cells)
 - increased RBC production by bone marrow

Shape

- poikilocytosis: increased proportion of RBCs of abnormal shape
 - iron deficiency anemia, myelofibrosis, severe B₁₂ deficiency, MDS, burns

Table 2. Common Erythrocyte Shapes

Shape	Definition	Associated Conditions
 Discocyte	Biconcave disc	Normal RBC
 Spherocyte	Spherical RBC (due to loss of membrane)	Hereditary spherocytosis, immune hemolytic anemia, post-transfusion
 Elliptocyte/Ovalocyte	Oval-shaped, elongated RBCs • Elliptocytes: the RBC long axis is $\geq 2x$ the length of the short axis • Ovalocytes: the RBC long axis is $< 2x$ the length of the short axis	Hereditary elliptocytosis, megaloblastic anemia, myelofibrosis, iron-deficiency, MDS (myelodysplastic syndrome)
 Schistocyte (helmet cell, fragment)	Fragmented cells (due to traumatic disruption of membrane)	Microangiopathic hemolytic anemia (HUS, aHUS, TTP, DIC, preeclampsia, HELLP, malignant HTN), vasculitis, glomerulonephritis, prosthetic heart valve
 Sickle Cell	Sickle-shaped RBC (due to polymerization of hemoglobin S)	Sickle cell disorders: HbSC, HbSS
 Codocyte (target cell)	"Bull's eye" on dried film	Liver disease, hemoglobin SC, thalassemia, iron deficiency, asplenia
 Dacryocyte (teardrop cell)	Single pointed end, looks like a teardrop	Myelofibrosis, thalassemia major, megaloblastic anemia, bone marrow infiltration
 Acanthocyte (spur cell)	Distorted RBC with irregularly distributed thorn-like projections (due to abnormal membrane lipids)	Severe liver disease (spur cell anemia), starvation/anorexia, post-splenectomy
 Echinocyte (burr cell)	RBC with numerous regularly spaced, small spiny projections	Uremia, HUS, burns, cardiopulmonary bypass, post-transfusion, storage artifact
 Rouleaux Formation	Aggregates of RBC resembling stacks of coins (due to increased plasma concentration of high molecular weight proteins)	Pregnancy is most common cause (due to physiological increase in fibrinogen) Inflammatory conditions (due to polyclonal immunoglobulins) Plasma cell dyscrasias (due to monoclonal paraproteinemia, e.g. multiple myeloma, macroglobulinemia) Storage artifact

DIC = disseminated intravascular coagulation; HELLP = hemolysis, elevated liver enzymes, and low platelet count; HUS = hemolytic uremic syndrome; aHUS = atypical HUS; TTP = thrombotic thrombocytopenic purpura
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

Table 3. RBC Inclusions

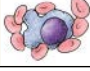

Inclusions	Definition	Associated Conditions
 Nucleus	Present in erythroblasts (immature RBCs)	Hyperplastic erythropoiesis (seen in hypoxia, hemolytic anemia), BM infiltration disorders, MPNs (MF)
 Heinz Bodies	Denatured and precipitated hemoglobin	G6PD deficiency (post-exposure to oxidant), thalassemia, unstable hemoglobins
 Howell-Jolly Bodies	Small nuclear remnant resembling a pyknotic nucleus	Post-splenectomy, hyposplenism (sickle cell disease), neonates, megaloblastic anemia
 Basophilic Stippling	Deep blue granulations indicating ribosome aggregation	Thalassemia, heavy metal (Pb, Zn, Ag, Hg) poisoning, megaloblastic anemia, hereditary (pyrimidine 5' nucleotidase deficiency)
 Sideroblasts	Erythrocytes with Fe containing granules in the cytoplasm	Hereditary, idiopathic, drugs, hypothyroidism (see <i>Sideroblastic Anemia, H16</i>), myelodysplastic syndrome, toxins (lead)

BM = bone marrow; MF = myelofibrosis; MPN = myeloproliferative neoplasm
Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012

WHITE BLOOD CELLS

- lymphocytes
 - comprise 30-40% of WBCs; great variation in “normal” lymphocyte morphology
- neutrophils
 - normally, only mature neutrophils (with 3-4 lobed nucleus) and band neutrophils (immediate precursor with horseshoe-shaped nucleus) are found in circulation
 - hypersegmented neutrophil: >5 lobes suggests megaloblastic process (B₁₂ or folate deficiency)
 - left shift (increased granulocyte precursors)
 - ♦ seen in leukemoid reactions: acute infections, pregnancy, neonates, hypoxia, shock, myeloproliferative neoplasms (CML, MF)
- blasts
 - immature, undifferentiated precursors; associated with acute leukemia, MDS, G-CSF (growth factor that stimulates neutrophil production) use

Table 4. Abnormal White Blood Cells on Film

Appearance	Definition	Associated Conditions
 Reed-Sternberg Cell	Giant, multinucleated B-lymphocyte, (classic 'owl-eye' morphology)	Primarily Hodgkin lymphoma, also seen in some non-Hodgkin lymphoma, CLL, and EBV infection
 Smudge Cell	Lymphocytes damaged during blood film preparation indicating cell fragility	CLL and other lymphoproliferative disorders Pathognomonic in EBV infection
 Auer Rod	Cytoplasmic inclusions that form long needles in the cytoplasm of myeloblasts	Pathognomonic for acute myeloid leukemia (AML)
 Atypical Lymphocyte	Pale blue cytoplasm following RBC edges with pink granules	Viruses (particularly EBV) T-cell large granular lymphocyte leukemia (T-LGL)

EBV = Epstein-Barr virus; CLL = chronic lymphocytic leukemia

Illustrations: Ayalah Hutchins and Merry Shiyu Wang 2012 and Danielle Sayeau 2017

Left Shift

Refers to an increase in granulocyte precursors in the peripheral smear (myelocytes, metamyelocytes, promyelocytes, blasts). If present, implies increased marrow production of granulocytes (e.g. inflammation, infection, G-CSF administration, CML)

The presence of predominantly blasts in the peripheral smear without cells between mature neutrophil and blast suggests clonal cell disorder (MDS, acute leukemias) If > 20% of the total WBC differential consists of blasts, this is acute leukemia and is a medical emergency

PLATELETS

- small, purple, anuclear cell fragments

Bone Marrow Aspiration and Biopsy

- sites: posterior iliac crest, sternum
- analyses: most often done together
 - aspiration: takes a fluid marrow sample for cellular morphology, flow cytometry, cytogenetics, molecular studies, microbiology (C&S, acid-fast bacilli, PCR)
 - ♦ note: differential diagnosis for a “dry tap”: MF, hairy cell leukemia, bone marrow infiltration
 - biopsy: takes a sample of intact bone marrow to assess histology (architecture) and immunohistochemistry
 - only aspirates, not biopsies, can be obtained from the sternal site

Indications

- unexplained CBC abnormalities
- diagnosis and evaluation of infiltrating cancers: plasma cell disorders, leukemias, solid tumours
- diagnosis and staging of lymphoma or solid tumours
- evaluate iron metabolism and stores (gold standard, but rarely done)
- evaluate suspected deposition and storage disease (e.g. amyloidosis, Gaucher's disease)
- evaluate fever of unknown origin, suspected mycobacterial, fungal/parasitic infections, or granulomatous disease
- evaluate unexplained splenomegaly
- confirm normal bone marrow in potential allogeneic hematopoietic cell donor

Important Considerations

- consult a hematologist prior to conducting a bone marrow biopsy on a patient with an inherited (e.g. hemophilia, vWF disease) or acquired (e.g. DIC, anticoagulant therapy, coagulopathy of liver disease, severe thrombocytopenia) bleeding diathesis to determine if pro-hemostatic therapy is indicated pre-procedure
- do not perform a bone marrow biopsy if there is evidence of infection over the targeted skin site

Common Presenting Problems

Anemia

Definition

- a decrease in RBC mass that can be detected by hemoglobin (Hb) concentration, hematocrit (Hct), and RBC count
 - adult males: Hb <130 g/L or Hct <0.41%
 - adult females: Hb <120 g/L or Hct <0.36% (changes with pregnancy and trimester)

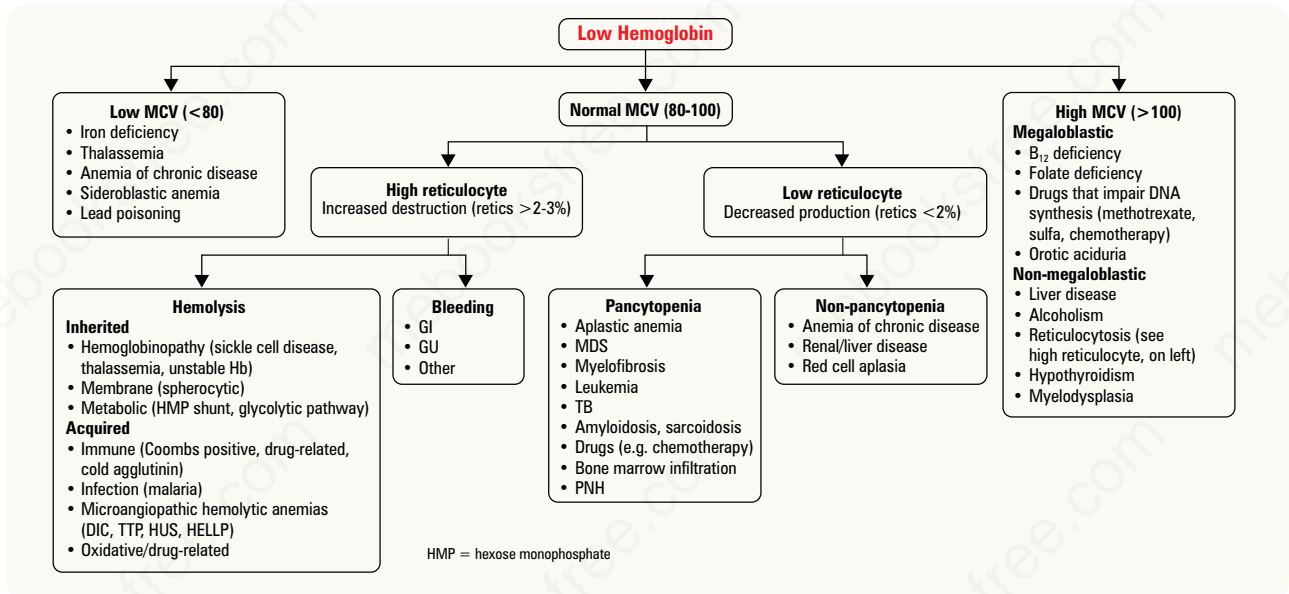

Figure 2. Approach to anemia – classification by size of RBC

Clinical Features

- history
 - symptoms of anemia: fatigue, headache, light-headedness, malaise, weakness, decreased exercise tolerance, dyspnea, palpitations, dizziness, tinnitus, syncope
 - acute vs. chronic, bleeding, systemic illness, diet (Fe, B₁₂ sources), alcohol, family history
 - menstrual history: menorrhagia, menometrorrhagia
 - rule out pancytopenia (recurrent infection, mucosal bleeding, easy bruising)
- physical signs
 - HEENT: pallor in mucous membranes and conjunctiva at Hb <90 g/L (<9 g/dL), ocular bruits at Hb <55 g/L (<5.5 g/dL), angular cheilitis, jaundice
 - cardiac: tachycardia, orthostatic hypotension, systolic flow murmur, wide pulse pressure, signs of CHF
 - dermatologic: ecchymosis, petechiae, pallor in palmar skin creases at Hb <75 g/L, jaundice (if due to hemolysis), nail changes (spooning), glossitis
 - splenomegaly, lymphadenopathy

Investigations

- rule out dilutional anemia (low Hb due to increased effective circulating volume)
- CBC with differential
- reticulocyte count and blood smear/film
- rule out nutritional deficit, gastrointestinal and genitourinary disease in iron deficiency anemia
- additional laboratory investigations as indicated (see *Microcytic Anemia*, H13, *Normocytic Anemia*, H17, *Hemolytic Anemia*, H18, and *Macrocytic Anemia*, H23)
- N.B. may have a mixed picture with multiple concomitant nutritional deficiencies

Reticulocytes

- Reticulocytes are immature erythrocytes and are markers of erythrocyte production (↑ colour, ↓ central pallor, ↑ size)
- The reticulocyte count should always be interpreted in the context of the Hb
- Should normally increase when there is a decrease in RBC
- With blood loss, reticulocytes should increase 2-3x initially and then 5-7x over the next week
- A normal reticulocyte count in anemia should be interpreted as a sign of decreased production, BM infiltration, or nutritional deficiency

Erythrocytosis

Definition

- an increase in the number of RBCs: Hb >185 g/L or Hct >52% (males); Hb >165 g/L or Hct >47% (females and African males)

Etiology

- relative/spurious erythrocytosis (decreased plasma volume): diuretics, severe dehydration, burns, “stress” (Gaisböck’s syndrome)
- absolute erythrocytosis

Table 5. Etiology of Erythrocytosis

Primary	Secondary	Inappropriate Production of Erythropoietin
Polycythemia Vera (PV) (see <i>Polycythemia Vera</i> , H41)	Physiologic (poor tissue oxygenation/hypoxia) Carbon monoxide poisoning Heavy smoking High altitude Pulmonary Disease COPD Sleep apnea Pulmonary hypertension Cardiovascular Disease R to L shunt (Eisenmenger syndrome) RBC defects (Hb with increased O ₂ affinity, methemoglobinemia)	Tumours Hepatocellular carcinoma Renal cell carcinoma Cerebellar hemangioblastoma Pheochromocytoma Uterine leiomyoma Ovarian tumour Other Polycystic kidney disease Post-kidney transplant Hydronephrosis Androgens Exogenous erythropoietin

Clinical Features

- secondary to high red cell mass and hyperviscosity
 - headache, dyspnea, dizziness, tinnitus, visual disturbances, hypertensive symptoms, numbness/tingling
 - symptoms of angina, congestive heart failure, aquagenic pruritus (only in MPNs)
- thrombosis (venous or arterial) or bleeding (seen with acquired vWD or acquired platelet dysfunction in MPNs)
- physical findings
 - splenomegaly ± hepatomegaly, facial plethora/ruddy complexion (70%) and/or palms, gout

Investigations

- serum erythropoietin (EPO): differentiates primary (low/normal) from other etiologies (elevated)
 - search for tumour as source of EPO as indicated (e.g. abdominal U/S, CT head)
 - JAK-2 mutation analysis: positive in >96% of cases of PV
 - only send if low/normal EPO level
- ferritin (iron deficiency can mask the diagnosis; if iron deficient with reticulocytosis, suggestive of PV)

Treatment

- if primary: see *Polycythemia Vera*, H41
- if secondary: treat underlying cause
 - O₂ for hypoxemia, CPAP for sleep apnea, surgery for EPO-secreting tumours
 - often cardiologists will be hesitant to treat high Hct in cyanotic patients

Thrombocytopenia

Definition

- platelet count <150 x 10⁹/L

Clinical Features

- history: mucocutaneous bleeding (easy bruising, gingival bleeding), epistaxis, peri-operative bleeding (including dental procedures), heavy menstrual bleeding, peripartum bleeding
- physical exam: bruising, petechiae, ecchymoses, non-palpable purpura, wet purpura
- see *Disorders of Primary Hemostasis*, H27 for complications

Investigations

- CBC and differential
- blood film
 - rule out pseudo-thrombocytopenia (platelet clumping or platelet satellitism)
 - decreased production: other cell line abnormalities, blasts, hypersegmented PMNs, leukoerythroblastic changes
 - increased destruction: large platelets (often seen in ITP), schistocytes (seen in MAHA/TMA)
- workup for nutritional deficiencies: B₁₂, RBC folate
- PT/INR, aPTT, and fibrinogen if DIC suspected
- LFTs

Treatments

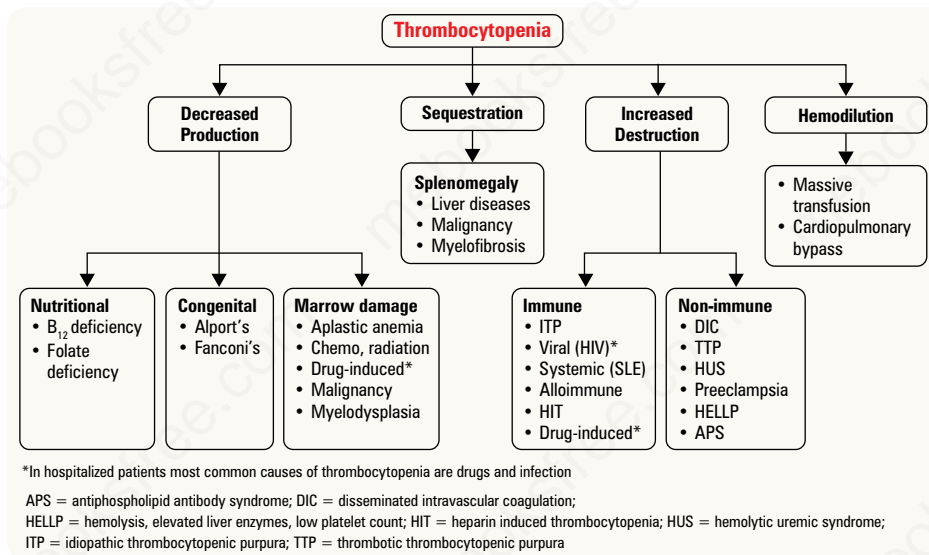

- life threatening bleeding: platelet transfusion (repeat CBC 1 h post-transfusion to confirm an appropriate rise in counts)
- if secondary: treat underlying cause
- ITP: see *Immune Thrombocytopenic Purpura*, H27

Rule-of-thumb: a deficit in all cell lines suggests decreased production, sequestration, or hemodilution, a deficit in platelets and RBCs suggests non-immune destruction, and an isolated thrombocytopenia suggests an immune-mediated process. In hospitalized patients, drugs and infection account for the majority of cases of thrombocytopenia

Must rule out factitious thrombocytopenia: platelet clumping (secondary to EDTA antibodies from collection tube). This can be seen on blood film and confirmed by repeating in a citrated sample (i.e. using a sodium citrate tube to collect blood, rather than EDTA)

Figure 3. Approach to thrombocytopenia

Adapted from: Cecil Essentials of Medicine

Thrombocytosis

Definition

- platelet count $>400 \times 10^9/L$
- primary thrombocytosis (uncommon): due to myeloproliferative neoplasms (e.g. CML, polycythemia vera, primary myelofibrosis, essential thrombocytosis; rarely associated with MDS)
- reactive/secondary thrombocytosis (common): acute phase reactant (e.g. surgery, inflammation, infection, trauma, bleeding, iron deficiency, neoplasms, ischemic injury)

Clinical Features

- history: trauma, surgery, splenectomy, infection, inflammation, bleeding, iron deficiency, prior diagnosis of chronic hematologic disorder, constitutional symptoms (malignancy)
- vasomotor symptoms: headache, visual disturbances, lightheadedness, atypical chest pain, acral dysesthesia, erythromelalgia, livedo reticularis, aquagenic pruritus
- clotting risk, bleeding risk (rare)
- physical exam: splenomegaly can be seen in myeloproliferative neoplasms (MPNs)

Investigations

- CBC, peripheral blood film, serum ferritin concentration
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- if reactive process has been ruled out, bone marrow biopsy may be required to rule out MPN/MDS

Treatment

- primary: ASA \pm cytoreductive agents (e.g. hydroxyurea, anagrelide, interferon- α)
- secondary: treat underlying cause

Pancytopenia

Definition

- a decrease in all hematopoietic cell lines

Clinical Features

- anemia: fatigue (see [Anemia, H6](#))
- leukopenia: recurrent infections (see [Neutropenia, H9](#))
- thrombocytopenia: mucosal bleeding (see [Thrombocytopenia, H7](#))

Investigations

- CBC, peripheral blood film, serum ferritin concentration, B₁₂, folate
- non-specific markers of infection or inflammation (e.g. CRP, ESR, ferritin)
- workup as per Figure 4 and presenting symptoms/physical exam
- if reactive process has been ruled out, bone marrow biopsy may be required

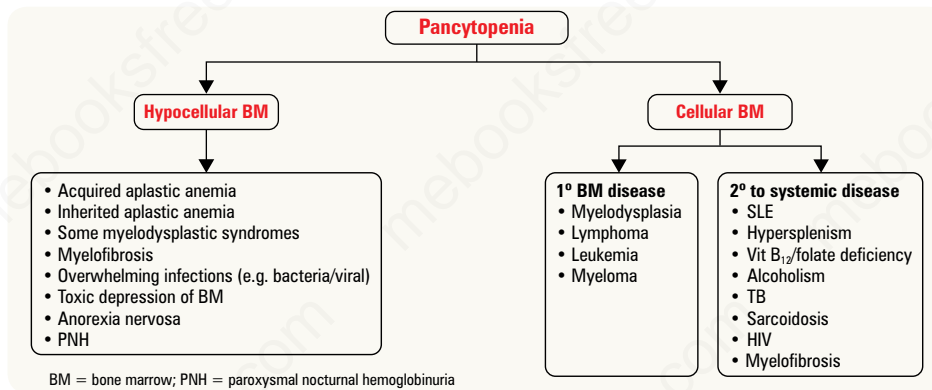

Figure 4. Approach to pancytopenia

Neutrophilia

Definition

- variable definition, but generally an absolute neutrophil count (ANC) $>7.7 \times 10^9/L$ (WHO definition)

Etiology

- primary neutrophilia
 - chronic myeloid leukemia (CML)
 - other myeloproliferative disorders: PV, ET, myelofibrosis
 - hereditary neutrophilia (autosomal dominant)
 - chronic idiopathic neutrophilia in otherwise healthy patients
 - leukocyte adhesion deficiency
- secondary neutrophilia
 - stress/exercise/epinephrine: movement of neutrophils from marginated pool into circulating pool
 - obesity
 - infection: leukocytosis with left shift \pm toxic granulation, Döhle bodies (intra-cytoplasmic structures composed of agglutinated ribosomes)
 - inflammation: e.g. rheumatoid arthritis (RA), IBD, chronic hepatitis, MI, PE, burns
 - malignancy: hematologic (i.e. marrow invasion by tumour) and non-hematologic (especially large cell lung cancer)
 - medications: glucocorticoids, β -agonists, lithium, G-CSF

Clinical Features

- look for signs and symptoms of fever, inflammation, malignancy to determine appropriate further investigations
 - including lymphadenopathy and organomegaly
- examine oral cavity, teeth, peri-rectal area, genitals, and skin for signs of infection

Investigations

- CBC and differential: mature neutrophils or bands $>20\%$ of total WBC suggests infection/inflammation
- blood film: Döhle bodies, toxic granulation, cytoplasmic vacuoles in infection
- may require bone marrow biopsy if MPN suspected

Treatment

- directed at underlying cause

Neutropenia

Definition

- mild: ANC $1.0-1.5 \times 10^9/L$
- moderate: ANC $0.5-1.0 \times 10^9/L$ (risk of infection starts to increase)
- severe: ANC $<0.5 \times 10^9/L$
- profound: ANC $<0.1 \times 10^9/L$ for >7 d

Absolute Neutrophil Count (ANC) = WBC count \times (%PMNs + %bands)

Beware of fever + ANC $<0.5 \times 10^9/L$ = FEBRILE NEUTROPENIA

Etiology

Table 6. Etiology of Neutropenia

Decreased Production	Peripheral Destruction/Sequestration	Excessive Margination (Transient Neutropenia)
Infection Viral hepatitis, EBV, HIV, TB, typhoid, malaria Hematological Diseases Idiopathic, aplastic anemia, myelofibrosis, BM infiltration, cyclic, PNH, MDS, immune-mediated Drug-Induced Alkylating agents, antimetabolites, anticonvulsants, antipsychotics, anti-inflammatory agents, anti-thyroid drugs Toxins/Chemicals High dose radiation, benzene, DDT Nutritional Deficiency B ₁₂ , folate Idiopathic Constitutional neutropenia, benign cyclic neutropenia	Anti-neutrophil antibodies Spleen or lung trapping Autoimmune disorders: RA (Felty's syndrome), SLE Granulomatosis with polyangiitis (formerly Wegener's) Drugs: haptens (e.g. α-methyl dopa)	Idiopathic (most common) Overwhelming bacterial infection Hemodialysis Cardiopulmonary bypass Racial variation (e.g. African or Ashkenazi Jewish descent)

Clinical Features

- fever, chills (only if infection present)
- infection by endogenous bacteria (e.g. *S. aureus*, gram negatives from GI and GU tract)
- painful ulceration on skin, anus, mouth, and throat following colonization by opportunistic organisms
- avoid digital rectal exam

Investigations

- dependent on degree of neutropenia, history, and symptoms
- ranges from observation with frequent CBCs to bone marrow aspiration and biopsy

Treatment

- regular dental care: chronic gingivitis and recurrent stomatitis major sources of morbidity
- treatment of febrile neutropenia (see [Infectious Diseases, ID45](#))
- in severe immune-mediated neutropenia, G-CSF may increase neutrophil counts
 - if no response to G-CSF, consider immunosuppression (e.g. steroids, cyclosporine, methotrexate)

Prophylactic Hematopoietic Colony-Stimulating Factors on Mortality and Infection

Ann Intern Med 2007;147:400-411

Purpose: To review the effects of colony-stimulating factor (CSF) on mortality, infections, and febrile neutropenia in patients undergoing chemotherapy or stem-cell transplant (SCT).

Study Selection: 148 RCTs comparing the effects of CSFs to either placebo or no therapy were included. Prophylactic CSFs were given concurrently with or after initiation of chemotherapy.

Results: There were no differences in all-cause mortality or infection-related death between CSF and placebo groups. Compared to placebo or no therapy, CSFs reduced infection rate (median rate 38.9% vs. 43.1%; rate ratio 0.85), microbiologically documented infections (MR 23.5% vs. 28.6%; rate ratio 0.86), and febrile neutropenia (MR 25.3% vs. 44.2%; rate ratio 0.71).

Conclusions: Prophylactic CSFs decrease infection rates and episodes of febrile neutropenia in patients undergoing chemotherapy or SCT, but have no effect on mortality.

G-CSF = Neupogen® = Filgrastim

Presence of atypical lymphocytes suggests viral infection

Presence of smudge cells suggests a lymphoproliferative disorder if persistently elevated above $5.0 \times 10^9/L$ for > 3 mo; consider flow cytometry of peripheral blood

Lymphocytosis

Definition

- absolute lymphocyte count $>4.0 \times 10^9/L$

Etiology

- infection (reactive lymphocytosis)
 - viral infections (majority); particularly mononucleosis
 - TB, pertussis, brucellosis, toxoplasmosis
- smoking
- physiologic response to stress (e.g. trauma, status epilepticus)
- hypersensitivity (e.g. drugs, serum sickness)
- autoimmune (e.g. rheumatoid arthritis)
- neoplasm (e.g. ALL if blasts present, CLL, B cell lymphocytosis of undetermined significance)

Investigations

- CBC, peripheral smear assessing lymphocyte morphology

Treatment

- treat underlying cause

Lymphopenia

Definition

- absolute lymphocyte count $<1.0 \times 10^9/L$

Etiology

- idiopathic CD4+ lymphocytopenia
- radiation
- HIV/AIDS, hepatitis B, hepatitis C
- malignancy/chemotherapeutic agents
- malnutrition, alcoholism
- autoimmune disease (e.g. SLE)

Clinical Features

- opportunistic infections (see [Infectious Diseases, ID34](#))

Treatment

- treat underlying cause
- treat opportunistic infections aggressively and consider antimicrobial prophylaxis (see [Infectious Diseases, ID30](#))

Eosinophilia

Definition

- absolute eosinophil count $>0.5 \times 10^9/L$

Etiology

- primary: due to clonal bone marrow disorder
 - if no primary etiology identified, classified as hypereosinophilic syndrome
 - 6 mo of eosinophilia (count $>1.5 \times 10^9/L$) with no other detectable causes and end organ damage
 - can involve heart, bone marrow, CNS
- secondary
 - most common causes are parasitic (usually helminth) infections and allergic reactions
 - less common causes
 - collagen vascular diseases (e.g. RA, polyarteritis nodosa, see [Rheumatology, RH19](#))
 - respiratory causes (asthma, eosinophilic pneumonia, Churg-Strauss)
 - cholesterol emboli
 - hematologic malignancy: see [Chronic Myeloid Leukemia, H40](#) and [Hodgkin Lymphoma, H45](#)
 - adrenal insufficiency, see [Endocrinology, E33](#)
 - medications (penicillins)
 - atopic dermatitis

Basophilia and/or Eosinophilia
Can be an indicator of CML or other myeloproliferative neoplasm, associated with pruritus due to excessive histamine production

Treatment

- treat underlying cause
- ensure strongyloides serology is collected to rule out infection before initiating steroids for patients at risk

Agranulocytosis

Definition

- severe depletion of granulocytes (neutrophils, eosinophils, basophils) from the blood and granulocyte precursors from bone marrow

Etiology

- associated with medications in 70% of cases: e.g. chemotherapy, clozapine, thionamides (antithyroid drugs), sulfasalazine, and ticlopidine
 - immune-mediated destruction of circulating granulocytes by drug-induced antibodies or direct toxic effects upon marrow granulocytic precursors

Clinical Features

- abrupt onset of fever, chills, weakness, and oropharyngeal ulcers

Prognosis

- high fatality without vigorous treatment

Investigations/Treatment

- discontinue offending drug
- pan-culture and screen for infection if patient is febrile (blood cultures x2, urine culture, and chest x-ray as minimum, initiate broad-spectrum antibiotics)
- consider bone marrow aspirate and biopsy if cause unclear
- consider G-CSF

Leukemoid Reaction

- blood findings resembling those seen in certain types of leukemia which reflect the response of healthy BM to cytokines released due to infection or trauma
- leukocytosis $>50 \times 10^9/L$, marked left shift (myelocytes, metamyelocytes, bands in peripheral blood smear)

Approach to Lymphadenopathy

History

- constitutional/B-symptoms: seen in TB, lymphoma, other malignancies
- growth pattern: acute vs. chronic
- exposures: cats (cat scratch – *Bartonella henselae*), ticks (Lyme disease – *Borrelia burgdorferi*), high risk behaviours (HIV)
- joint pain/swelling, rashes (connective tissue disorder)
- pruritus (seen in Hodgkin lymphoma)
- medications (can cause serum sickness → lymphadenopathy)

Constitutional/B-Symptoms

- Unexplained temperature $>38^\circ C$
- Unexplained weight loss ($>10\%$ of body weight in 6 mo)
- Night sweats

Clinical Features

- determine if lymphadenopathy is localized or generalized
- localized: typically reactive or neoplastic
 - cervical (bacterial/mycobacterial infections, ENT malignancies, metastatic cancer)
 - supraclavicular
 - ♦ right (mediastinal, bronchogenic, esophageal cancer)
 - ♦ left (gastric, gall bladder, pancreas, renal, testicular/ovarian cancer)
 - axillary (cat scratch fever, breast cancer, metastatic cancer)
 - epitrochlear (infections, sarcoidosis, lymphoma)
 - check for splenomegaly, constitutional symptoms

Drugs that can cause Lymphadenopathy

- Allopurinol
- Atenolol
- Captopril
- Carbamazepine
- Cephalosporins
- Gold
- Hydralazine
- Penicillin
- Phenytoin
- Primidone
- Pyrimethamine
- Quinidine
- Sulfonamides
- Sulindac

Investigations

- CBC and differential, blood film
- if generalized, consider tuberculin test, HIV RNA, VDRL, Monospot®/EBV serology, ANA, imaging
- if localized and no symptoms suggestive of malignancy, can observe 3-4 wk (if no resolution → biopsy)
- excisional biopsy is preferred as it preserves node architecture (essential for diagnosing lymphoma)
- in areas difficult to access (retroperitoneal, mediastinal/hilar) multiple core biopsies may be more practical/feasible
- FNA should NOT be used for diagnostic purposes in lymphoproliferative disease (use excisional biopsy instead)
 - FNA is helpful for recurrence of solid tumour malignancy
 - imaging such as U/S or CT can provide more info, but generally adds little to diagnosis

Table 7. Inflammatory vs. Neoplastic Lymph Nodes

Feature	Inflammatory	Neoplastic
Consistency	Rubbery	Firm/hard
Mobility	Mobile	Matted/immobile
Tenderness	Tender	Non-tender
Size	<2 cm	>2 cm

*Note: these classifications are not absolute; lymphoma and CLL nodes can feel rubbery and are frequently mobile, non-tender

Table 8. Differential Diagnosis of Generalized Lymphadenopathy

Reactive	Inflammatory	Neoplastic
Bacterial (TB, Lyme, brucellosis, cat scratch disease, syphilis)	Collagen disease (RA, dermatomyositis, SLE, vasculitis, Sjögren's)	Lymphoproliferative disorder/lymphoma Metastatic cancer Histiocytosis X
Viral (EBV, CMV, HIV)	Drug hypersensitivity	
Parasitic (toxoplasmosis)	Sarcoidosis, amyloidosis	
Fungal (histoplasmosis)	Serum sickness	

Approach to Splenomegaly

Table 9. Differential Diagnosis of Splenomegaly

Increased Demand for Splenic Function			Congestive	Infiltrative
Hematological Nutritional anemias Hemoglobinopathies Hemolysis Spherocytosis Sequestration crisis Elliptocytosis	Infectious Viral e.g. EBV, HIV/ AIDS, CMV Bacterial e.g. Bacterial endocarditis, TB Parasitic e.g. Malaria, Histoplasmosis, Leishmaniasis Fungal	Inflammatory SLE Sarcoidosis Felty syndrome Still's disease	Cirrhosis <u>Portal HTN</u> Portal vein obstruction (including right heart failure) Splenic vein thrombosis	Non-Malignant Benign metaplasia Cysts Amyloidosis, Sarcoidosis Hamartomas Vascular abnormalities <u>Lysosomal storage diseases</u> (Gaucher's, Niemann-Pick) Glycogen storage diseases Malignant <u>Leukemia (CML, CLL)</u> <u>Lymphoproliferative disease</u> <u>Hodgkin lymphoma</u> <u>Myeloproliferative disorders</u> Metastatic tumour

The underlined conditions cause massive splenomegaly (spleen crosses midline or reaches pelvis)

Causes of Splenomegaly

CHINA

- Cirrhosis/Congestion (portal HTN)
- Hematological
- Infectious
- Neoplasm (malignant, non-malignant)
- Autoimmune

History

- constitutional symptoms, feeling of fullness in LUQ, early satiety
- signs or symptoms of infection (e.g. mononucleosis) or malignancy
- history of liver disease, hemolytic anemia, or high-risk exposures

Clinical Features

- jaundice, petechiae
- signs of chronic liver disease
- percussion (Castell's sign, Traube's space, Nixon's method) and palpation
- associated lymphadenopathy or hepatomegaly
- signs of CHF

Investigations

- CBC and differential, blood film
- as indicated: liver enzymes (AST, ALT, ALP, GGT) and/or LFTs (platelet, INR, albumin, bilirubin), reticulocyte count, Monospot®/EBV, haptoglobin, LDH, infectious, and autoimmune workup
- imaging
 - ultrasound of abdomen/liver to assess for cirrhosis and portal vein thrombosis (if positive, refer to hepatology for evaluation)
 - echo for cardiac function
 - CT to rule out lymphoma and assess splenic lesions

Microcytic Anemia

- MCV <80 fL
- see Figure 2, Approach to Anemia, H6

Table 10. Iron Indices and Blood Film in Microcytic Anemia

	Lab Tests				RDW	Blood Film
	Ferritin	Serum Iron	TIBC	% saturation		
Iron Deficiency Anemia	↓↓	↓	↑	↓	↑ (>15)	Hypochromic, microcytic
Anemia of Chronic Disease	N/↑	↓	↓	N	N	Normocytic/microcytic
Sideroblastic Anemia	N/↑	↑	N	N/↑	↑	Dual population Basophilic stippling
Thalassemia	N/↑	N/↑	N	N/↑	N/↑	Hypochromic, microcytic Basophilic stippling Poikilocytosis

Causes of Microcytic Anemia

TAILS

- Thalassemia
- Anemia of chronic disease
- Iron deficiency
- Lead poisoning
- Sideroblastic anemia

Iron Metabolism

Iron Intake (Dietary)

- average North American adult diet = 10-20 mg iron (Fe) daily
- steady state absorption is 5-10% (0.5-2 mg/d); enhanced by citric acid, ascorbic acid (vitamin C) and reduced by polyphenols (e.g. in tea), phytate (e.g. in bran), dietary calcium, and soy protein
- males have positive Fe balance; up to 20% of menstruating females have negative Fe balance

Iron Absorption and Transport

- dietary iron is absorbed in the duodenum (e.g. absorption impaired in IBD and Celiac disease)
- in circulation the majority of non-heme iron is bound to transferrin which transfers iron from enterocytes and storage pool sites (macrophages of the reticuloendothelial system and hepatocytes) to RBC precursors in the bone marrow

Iron Levels

- hepcidin is a hormone produced by hepatocytes that regulates systemic iron levels
 - binds to iron exporter ferroportin (on duodenal enterocytes and reticuloendothelial cells) and induces its degradation, thereby inhibiting iron export into circulation (diminished absorption of iron and iron trapping in reticuloendothelial system cells)
 - hepcidin production is:
 - ◆ increased in states of iron overload (inhibiting additional iron absorption) and inflammation (mediating anemia of chronic inflammation through iron trapping)
 - ◆ decreased in states where erythropoiesis is increased (e.g. hemolysis) or oxygen tension is low

Iron Storage

- ferritin
 - ferric iron (Fe^{3+}) complexed to a protein called apoferritin (hepatocytes are main ferritin storage site)
 - small quantities are present in plasma in equilibrium with intracellular ferritin
 - also an acute phase reactant – can be spuriously elevated despite low Fe stores in response to a stressor
- hemosiderin
 - aggregates or crystals of ferritin with the apoferritin partially removed
 - macrophage-monocyte system is main source of hemosiderin storage

Figure 5. Iron metabolism

Iron Indices

- bone marrow aspirate: gold standard test for assessment of iron stores (rarely done)
- serum ferritin: most important blood test for iron stores
 - decreased in iron deficiency anemia
 - elevated in infection, inflammation, malignancy, liver disease, hyperthyroidism, and iron overload
- serum iron: measure of all non-heme iron present in blood
 - varies significantly daily
 - virtually all serum iron is bound to transferrin, only a trace is free or complexed in ferritin
- total iron binding capacity (TIBC): total amount of transferrin present in blood
 - normally, one third of TIBC is saturated with iron
 - high specificity for decreased iron, low sensitivity
- saturation
 - serum Fe divided by TIBC, expressed as a proportion or a percentage
- soluble transferrin receptor (sTfR)
 - reflects the availability of iron at the tissue level
 - the transferrin receptor is expressed on the surface of erythroblasts and is responsible for iron uptake – some is cleaved off and is present in circulation as sTfR
 - in iron deficient states more transferrin receptor is expressed on erythroblasts leading to an increase in sTfR
 - low in reduced erythropoiesis and iron overload
 - useful in determining iron deficiency in the setting of chronic inflammatory disorders (see *Iron Deficiency Anemia*)

Iron Deficiency Anemia

- see [Pediatrics, P41](#)
- most common cause of anemia in North America

Etiology

- increased demand
 - increased physiological need for iron in the body (e.g. pregnancy)
- decreased supply: dietary deficiencies (rarely the only etiology in the developed world)
 - cow's milk (infant diet), "tea and toast" diet (elderly), absorption imbalances, post-gastrectomy, malabsorption (IBD of duodenum, celiac disease, autoimmune atrophic gastritis, *H.pylori* infection)
- increased losses
 - hemorrhage
 - ♦ obvious causes: menorrhagia, abnormal uterine bleeding, frank GI bleed
 - ♦ occult: peptic ulcer disease, GI cancer
 - hemolysis
 - ♦ chronic intravascular hemolysis (e.g. PNH, cardiac valve RBC fragmentation)

Clinical Features

- iron deficiency may cause fatigue before clinical anemia develops
- signs/symptoms of anemia: see [Anemia, H6](#)
- brittle hair, nail changes (brittle, koilonychia)
- pica (appetite for non-food substances e.g. ice, paint, dirt)
- restless leg syndrome

Investigations

- iron indices, including soluble transferrin receptor
 - low ferritin (<18 µg/L) is diagnostic of iron deficiency
 - ferritin is an acute phase reactant and is elevated in the setting of inflammatory conditions and liver disease; serum ferritin <100 µg/L in these settings is suggestive of iron deficiency, necessitating further workup
- peripheral blood film
 - hypochromic microcytosis: RBCs have low Hb levels due to lack of iron
 - pencil forms, anisocytosis
 - target cells
- bone marrow (gold standard but rarely done)
 - iron stain (Prussian blue) shows decreased iron in macrophages and in erythroid precursors (sideroblasts)
 - intermediate and late erythroblasts show micronormoblastic maturation

Plummer-Vinson Syndrome

- Dysphagia (esophageal)
- Glossitis
- Iron deficiency anemia
- Stomatitis

Iron deficiency anemia is a common presentation of chronic lower GI bleeds (right-sided colorectal cancer, angiodysplasia, etc.)

In males and in post-menopausal women, a GI workup is always warranted (gastroscopy, colonoscopy)

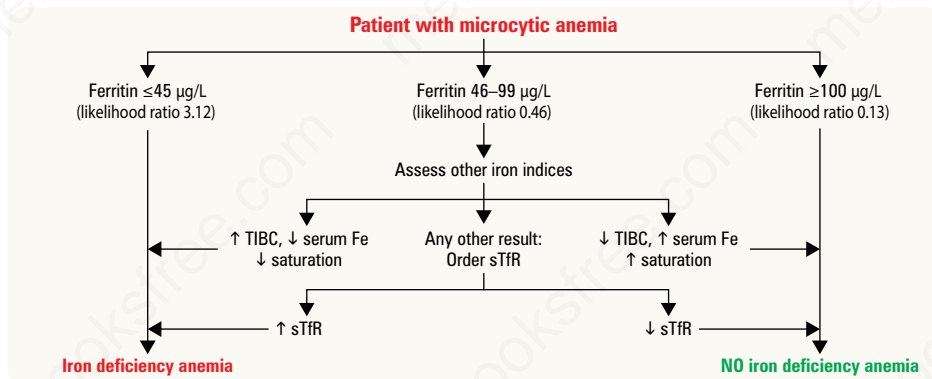

Figure 6. Approach to interpreting iron indices

Adapted from: *Am Fam Physician* 2007;75:671-678

Treatment

- treat underlying cause
- supplementation
 - oral (capsules, syrup)
 - ♦ ferrous sulphate 325 mg tid (65 mg elemental iron), ferrous gluconate 300 mg tid (35 mg elemental iron), or ferrous fumarate 300 mg tid (100 mg elemental iron)
 - ♦ supplement until anemia corrects, then continue for 3⁺ mo until serum ferritin returns to normal
 - ♦ oral iron should be taken with citrus juice (vitamin C) to enhance absorption
 - IV (iron sucrose or dextran) can be used if patient cannot tolerate or absorb oral iron
- monitoring response
 - reticulocyte count will begin to increase after one wk
 - Hb normalizes by 10 g/L per wk (if no blood loss)

Anemia of Chronic Inflammation

Etiology

- infection, malignancy, inflammatory and rheumatologic disease, chronic renal and liver disease, endocrine disorders (e.g. DM, hypothyroidism, hypogonadism, hypopituitarism)

Pathophysiology

- an anemia of underproduction due to impaired iron utilization (hepcidin is a key regulatory peptide)
 - hepatic hepcidin production is increased in inflammatory processes, trapping iron in enterocytes and macrophages (via ferroportin inhibition), see Figure 5
 - reduced plasma iron levels make iron relatively unavailable for new hemoglobin synthesis
 - marrow unresponsive to normal or slightly elevated EPO
- mild hemolytic component is often present i.e. RBC survival is modestly decreased

Investigations

- diagnosis of exclusion
- associated with elevation in acute phase reactants (ESR, CRP, fibrinogen, platelets)
- peripheral blood
 - mild: usually normocytic and normochromic
 - moderate: may be microcytic and normochromic
 - severe: may be microcytic and hypochromic
 - absolute reticulocyte count is frequently low, reflecting overall decrease in RBC production
- “classic” serum iron indices
 - serum iron and TIBC low, % saturation low
 - serum ferritin is normal or increased
- bone marrow
 - normal or increased iron stores
 - decreased or absent staining for iron in erythroid precursors

Treatment

- treat underlying disease
- only treat anemia in patients who can benefit from a higher hemoglobin
- IV iron if no benefit from PO iron (overcomes sequestration in enterocytes)
- erythropoietin indicated in chronic renal failure; not to be used if patient has concomitant curative solid tumour malignancy; ensure Hb target <110 g/L

Sideroblastic Anemia

- uncommon compared to iron deficiency anemia or anemia of chronic disease

Sideroblasts

- erythrocytes with iron-containing (basophilic) granules in the cytoplasm
- “normal”: in healthy individuals, granules are small and randomly spread in the cytoplasm
- “ring”: iron deposits in mitochondria, forming large, abnormal granules that surround the nucleus
 - the hallmark of sideroblastic anemia

Etiology

- due to defects in heme biosynthesis in erythroid precursors
- hereditary (rare): X-linked; median survival 10 yr
- idiopathic (acquired)
 - refractory anemia with ringed sideroblasts: a subtype of MDS (see *Myelodysplastic Syndromes, H39*)
 - may be a preleukemic phenomenon (10% transform to AML)
- reversible
 - drugs (isoniazid, chloramphenicol), alcohol, lead, copper deficiency, zinc toxicity, hypothyroidism

Clinical Features

- anemia symptoms (see *Anemia, H6*)
- hepatosplenomegaly, evidence of iron overload

Investigations

- serum iron indices
 - increased serum Fe²⁺, normal TIBC, increased ferritin, increased sTfR
- blood film/bone marrow biopsy
 - ringed sideroblasts (diagnostic hallmark)
 - RBCs are hypochromic; can be micro-, normo-, or macrocytic
 - anisocytosis, poikilocytosis, basophilic stippling

Treatment

- depends on etiology
 - X-linked: high dose pyridoxine (vitamin B₆) in some cases
 - acquired: EPO and G-CSF
 - reversible: remove precipitating cause
- supportive transfusions for severe anemia

Consider lead poisoning in any child with microcytic anemia who lives in a house built before 1977

Features of Lead Poisoning

LEAD
 Lead lines on gingivae and epiphyses of long bones on x-ray
 Encephalopathy and Erythrocyte basophilic stippling
 Abdominal colic and microcytic Anemia (sideroblastic)
 Drops (wrist and foot drop)

Causes of Normocytic Anemia

ABCD
 Acute blood loss
 Bone marrow failure
 Chronic disease
 Destruction (hemolysis)

Lead Poisoning

Definition/Etiology

- blood lead levels greater than 80 µg/dL, possible symptomatology at 50 µg/dL
- identify source: consider occupational history, exposures history, utensil history

Clinical Features

- abdominal pain, constipation, irritability, difficulty concentrating

Treatment

- chelation therapy: dimercaprol and EDTA are first line agents

Normocytic Anemia

- MCV 80-100 fL
- see Figure 2, Approach to Anemia, H6

Aplastic Anemia

Definition

- destruction of hematopoietic cells of the bone marrow leading to pancytopenia and hypocellular bone marrow

Etiology

Table 11. Etiology of Aplastic Anemia

Congenital	Acquired	
Fanconi's anemia Shwachman-Diamond syndrome	Idiopathic Often T-cell mediated Drugs Dose-related (i.e. chemotherapeutics) Idiosyncratic (chloramphenicol, anti-malarials, phenylbutazone) Toxins Benzene/organic solvents DDT, insecticides	Ionizing Radiation Post-Viral Infection Parvovirus B19, EBV, HDV, HEV, HBV, HHV6, HIV Autoimmune (rare) SLE, Graft-versus-host disease Others PNH, pregnancy, anorexia nervosa, thymoma

Clinical Features

- can present acutely or insidiously
- symptoms of anemia (see Anemia, H6), thrombocytopenia (see Thrombocytopenia, H7), and/or infection
- ± splenomegaly and lymphadenopathy (depending on the cause)

Investigations

- exclude other causes of pancytopenia (see Figure 4), including PNH (overlap syndrome)
- CBC
 - anemia, neutropenia or thrombocytopenia (any combination) ± pancytopenia
 - decreased reticulocytes (<1% of the total RBC count)
- blood film
 - decreased number of normal RBCs
- bone marrow
 - aplasia or hypoplasia of marrow cells with fat replacement
 - decreased cellularity

Treatment

- remove offending agents
- supportive care (red cell and platelet transfusions, antibiotics)
 - judicious use so as to not increase the risk of immune sensitization to blood products
- immunosuppression (for idiopathic aplastic anemia)
 - anti-thymocyte globulin: 50-60% of patients respond
 - cyclosporine
- allogeneic bone marrow transplant
- growth factors: e.g. Eltrombopag (TPO receptor agonist), G-CSF, and EPO not effective

Hemolytic Anemia

Definition

- anemia due to a shortened survival of circulating RBCs, usually defined as <100 d
- uncommon cause for anemia ($<5\%$ of cases) with many etiologies (>200)

Classification

- hereditary
 - abnormal membrane (spherocytosis, elliptocytosis)
 - abnormal enzymes (pyruvate kinase deficiency, G6PD deficiency)
 - abnormal hemoglobin synthesis (thalassemias, hemoglobinopathies)
- acquired
 - immune
 - ♦ autoimmune: warm vs. cold autoimmune hemolytic anemias (AIHA), see Table 14 Classification of AIHA, H22
 - ♦ alloimmune: hemolytic disease of the fetus/newborn, post-transfusion
 - non-immune
 - ♦ MAHA/TMA, now known as TMA: thrombus in blood vessel causes RBCs to be sheared – associated with DIC, HUS, aHUS, TTP, preeclampsia/HELLP, vasculitides, malignant hypertension
 - ♦ other causes: PNH, hypersplenism, march hemoglobinuria (exertional hemolysis), infection (e.g. malaria), snake venoms, mechanical heart valves
- also classified as intravascular or extravascular
 - intravascular: MAHA/TMA (e.g. TTP, DIC), infections (malaria, Clostridium), and PNH
 - extravascular: RBCs are coated with antibodies (AIHA) or have an abnormal membrane structure/shape or inclusions

Clinical Features Specific to HA

- jaundice
- dark urine (hemoglobinuria, bilirubin)
- cholelithiasis (pigment stones)
- potential for an aplastic crisis (i.e. BM suppression in overwhelming infection)
- iron overload with extravascular hemolysis
- iron deficiency with intravascular hemolysis

Investigations

Table 12. Investigations for Hemolytic Anemia

Screening Tests	Tests Specific For Intravascular Hemolysis
Increased LDH	Schistocytes on blood film
Decreased haptoglobin	Free hemoglobin in serum
Increased unconjugated bilirubin	Methemalbuminemia (heme + albumin)
Increased urobilinogen	Hemoglobinuria (immediate)
Reticulocytosis	Hemosiderinuria (delayed) – most sensitive

Tests Specific for Extravascular Hemolysis
Direct Antiglobulin Test (direct Coombs)
Detects IgG or complement on the surface of RBC
Add anti-IgG or anti-complement Ab to patient's RBCs; positive if agglutination
Indications: hemolytic disease of newborn, AIHA, hemolytic transfusion reaction
Indirect Antiglobulin Test (indirect Coombs)
Detects antibodies in serum that can recognize antigens on RBCs
Mix patient's serum + donor RBCs + Coombs serum (anti-human Ig Ab); positive if agglutination
Indications: cross-matching donor RBCs, atypical blood group, blood group Ab in pregnant women, AIHA

On blood film schistocytes reflect an intravascular hemolysis while spherocytes usually reflect an extravascular hemolysis

Disruption of the heme breakdown pathway causes the **porphyria** disorders

Heme Breakdown

Laboratory Findings in HA

- \uparrow retics
- \downarrow haptoglobin
- \uparrow unconjugated bilirubin
- \uparrow urobilinogen
- \uparrow LDH

Haptoglobin is a circulating protein that mops up free hemoglobin, allowing its clearance in the spleen; when there is abundant free hemoglobin, haptoglobin is consumed, and levels decrease

Thalassemia

β -Thal \rightarrow prevalent in Mediterranean
 α -Thal \rightarrow prevalent in South East Asia (SEA) and Africa (α = Asia, Africa)

Thalassemia

Definition

- defects in production of the α or β chains of hemoglobin
 - resulting imbalance in globin chains leads to ineffective erythropoiesis and hemolysis in the spleen or BM
- clinical manifestations and treatment depends on specific gene and number of alleles affected
- common features
 - increasing severity with increasing number of alleles involved
 - hypochromic microcytic anemia
 - basophilic stippling, abnormally shaped RBCs on blood film

Pathophysiology

- defect may be in any of the Hb genes
 - normally 4 α genes in total; 2 on each copy of chromosome 16
 - normally 2 β genes in total; 1 on each copy of chromosome 11
 - fetal hemoglobin, HbF ($\alpha 2\gamma 2$), switches to adult forms HbA ($\alpha 2\beta 2$) and HbA2 ($\alpha 2\delta 2$) at 3-6 mo of life
 - HbA constitutes 97% of adult hemoglobin
 - HbA2 constitutes 3% of adult hemoglobin

 β -Thalassemia Minor (Thalassemia Trait)**Definition**

- defect in single allele of β gene (heterozygous for one normal β globin allele and one β globin thalassemic allele)
- common in people of Mediterranean and Asian descent

Clinical Features

- usually asymptomatic; a palpable spleen is very rare

Investigations

- Hb (100-140 g/L), MCV (<70 fL), Fe (normal), RBC count (normal)
- peripheral blood film – microcytosis basophilic stippling
- Hb electrophoresis
 - specific: HbA2 increased to 3.5-5% (normal 1.5-3.5%)
 - non-specific: 50% have slight increase in HbF

Treatment

- no treatment required
- genetic counselling for patient and family

 β -Thalassemia Major**Definition**

- defect in both alleles of β gene (homozygous, autosomal recessive)

Pathophysiology

- ineffective chain synthesis leading to ineffective erythropoiesis, hemolysis of RBCs, and increase in HbF

Clinical Features

- initial presentation at age 6-12 mo when HbA ($\alpha 2/\beta 2$) normally replaces HbF ($\alpha 2/\gamma 2$)
 - severe anemia, jaundice
- iron overload progressing to hemochromatosis
 - secondary to repeated transfusions and ineffective erythropoiesis
 - leads to iron-induced organ damage
- stunted growth and development (hypogonadal dwarf)
- gross hepatosplenomegaly (due to extramedullary hematopoiesis)
- radiologic changes (due to expanded marrow cavity) and extramedullary hematopoietic masses (erythroid tissue tumours)
 - skull x-ray has “hair-on-end” appearance
 - pathologic fractures common
- evidence of increased Hb catabolism (e.g. pigmented gallstones)
- death can result from
 - untreated anemia (should transfuse)
 - infection (should identify and treat early)
 - iron overload (common): late complication from repeated transfusions and ineffective erythropoiesis

Investigations

- severe microcytic anemia (Hb <60 g/L)
- peripheral blood film: teardrop, target, hypochromatic, microcytic
- Hb electrophoresis
 - HbA: 0-10% (normal >95%)
 - HbA2 >2.5%
 - HbF: 90-100%

Treatment

- lifelong regular transfusions to suppress endogenous erythropoiesis
- iron chelation (e.g. deferoxamine, deferasirox, deferiprone) to prevent iron overload in organs and the formation of free radicals (which promote tissue damage and fibrosis)
- folic acid supplementation if not transfused
- allogeneic bone marrow transplantation (potentially curative) or cord blood transplant
- splenectomy (now performed less frequently)

**Microcytosis in β -Thal Minor**

Microcytosis is much more profound and the anemia is much milder than that of iron deficiency

**Hemochromatosis Clinical Features****ABCDH**

Arthralgia
Bronze skin
Cardiomyopathy, cirrhosis of liver
Diabetes (pancreatic damage)
Hypogonadism (anterior pituitary damage)

β -Thalassemia Intermedia

Definition

- clinical diagnosis in patients whose clinical manifestations are too mild to be classified as thalassemia major, but too severe to be classified as thalassemia minor

Clinical Features

- wide variety of clinical phenotypes
- in most cases of TI, both β -globin genes affected
- three main mechanisms account for the milder phenotype compared to thalassemia major: (1) subnormal (vs. absent) β -chain synthesis, (2) increased number of γ chains, (3) coinheritance of α thalassemia (in some cases)
- complications more commonly seen in TI than thalassemia major include extramedullary hematopoiesis, leg ulcers, gallstones, thrombosis, and pulmonary hypertension, and growth retardation

α -Thalassemia

Definition

- defect(s) in α genes
- similar geographic distribution as β -thalassemia, but higher frequency among Asians and Africans

Clinical Features

- 1 defective α gene ($\alpha\alpha/a-$): clinically silent; normal Hb, normal MCV
- 2 defective α genes (cis: $\alpha\alpha/--$ or trans: $a-/a-$): decreased MCV, normal Hb
 - N.B. cis 2-gene deletion more common in Asia vs. trans 2-gene deletion more common in Africa – this leads to increased risk of fetal hydrops in offspring of Asian patients vs. African patients
- 3 defective α genes ($a-/-$): HbH (β_4) disease; presents in adults, decreased MCV, decreased Hb, splenomegaly
- 4 defective α genes ($---/---$): Hb Barts (γ_4) disease (hydrops fetalis); usually incompatible with life

Investigations

- peripheral blood film – screen for HbH inclusion bodies with supravital stain
- electrophoresis can be used to identify HgH disease, definitive diagnosis with DNA genotyping

Treatment

- depends on degree of anemia, referral for genetic/prenatal counselling
 - 1 or 2 defective α genes: no treatment required
 - HbH disease: similar to β -thalassemia intermedia
 - HbBarts: no definitive treatment, majority of pregnancies terminated (fetal/maternal mortality risk), intrauterine transfusion, stem cell transplants

Sickle Cell Disease

Definition

- autosomal recessive sickling disorders arise due to a mutant β -globin chain, most commonly caused by a Glu \rightarrow Val substitution at position 6 (chromosome 11) resulting in HbS variant, rather than HbA (normal adult Hb)
 - increased incidence of HbS allele with African or Mediterranean heritage (thought to be protective against malaria)
- sickle cell disease occurs when an individual has two HbS genes (homozygous, HbSS) or one HbS gene + another mutant β -globin gene (compound heterozygote) – most commonly HbS- β -thal and HbSC disease

Pathophysiology

- at low pO_2 , deoxy HbS polymerizes leading to rigid crystal-like rods that distort membranes \rightarrow 'sickles'
- the pO_2 level at which sickling occurs is related to the percentage of HbS present
- sickling aggravated by acidemia, increased CO_2 , increased 2,3-DPG, fever, and osmolality
- fragile sickle cells then cause injury in two main ways
 - fragile sickle cells hemolyze (nitric oxide depletion)
 - occlusion of small vessels (hypoxia, ischemia-reperfusion injury)

Clinical Features

- HbAS (sickle cell trait): patient will be asymptomatic except during extreme hypoxia or infection increased risk of renal medullary carcinoma
- SCD-SS (HbSS)
 - chronic hemolytic anemia
 - jaundice in the first yr of life
 - retarded growth and development \pm skeletal changes
 - splenomegaly in childhood; splenic atrophy in adulthood

Figure 7. Pathophysiology of sickling

Functional asplenia: increased susceptibility to infection by encapsulated organisms

- S. pneumoniae*
- N. meningitidis*
- H. influenzae*
- Salmonella* (osteomyelitis)

- SCD-SS often presents with acute pain episode
 1. aplastic crises
 - ♦ toxins and infections (especially parvovirus B19) transiently suppress bone marrow
 2. splenic sequestration crises
 - ♦ usually in children; significant pooling of blood in spleen resulting in acute Hb drop and shock
 - ♦ uncommon in adults due to asplenia from repeated infarction
 3. vaso-occlusive crises (infarction)
 - ♦ may affect various organs causing ischemia-reperfusion injury (especially in back, chest, abdomen, and extremities), fever, and leukocytosis
 - ♦ can cause a stroke or a silent myocardial infarction
 - ♦ precipitated by infections, dehydration, rapid change in temperature, pregnancy, menses, and alcohol
 4. acute chest syndrome
- SCD-SC (most common compound heterozygote)
 - 1:833 live births in African-Americans, common in West Africa
 - milder anemia than HbSS
 - similar complications as HbSS, although typically milder and less frequent (exception is proliferative sickle retinopathy, glomerulonephritis, and avascular necrosis)
 - spleen not always atrophic in adults

Investigations

- sickle cell prep (detects sickling of RBCs under the microscope in response to O₂ lowering agent): determines the presence of a HbS allele, but does not distinguish HbAS from HbSS
- Hb electrophoresis distinguishes HbAS, HbSS, HbSC, and other variants
- all newborns in developed countries typically screened for SCD

Table 13. Investigations for Sickle Cell Disease

	HbAS	HbSS
CBC	Normal	Increased reticulocytes, decreased Hb, decreased Hct
Peripheral Blood	Normal; possibly a few target cells	Sickled cells
Hb Electrophoresis	HbA fraction of 0.65 (65%) HbS fraction of 0.35 (35%)	No HbA, only HbS and HbF (proportions change with age); normal amount of HbA2

Treatment

- genetic counselling
- HbAS: no treatment required
- HbSC: treatment as per HbSS, but is dictated by symptom severity
- HbSS
 1. folic acid to prevent folate deficiency
 2. hydroxyurea to enhance production of HbF
 - ♦ mechanism of action: stops repression of Hb- γ chains and/or initiates differentiation of stem cells in which this gene is active
 - ♦ presence of HbF in the SS cells decreases polymerization and precipitation of HbS
 - ♦ N.B. hydroxyurea is cytotoxic and may cause bone marrow suppression
 3. treatment of vaso-occlusive crisis
 - ♦ supportive care: oxygen, hydration (reduces viscosity), correct acidosis, analgesics/opiates
 - ♦ indication for exchange transfusion: Hb <50-60 g/L, SCD complications (acute chest syndrome, aplastic crisis, hepatic or splenic sequestration, stroke), prevention of complications, pre-operative
 - ♦ less routinely: antimicrobials for suspected infection
 4. prevention of crises
 - ♦ establish diagnosis
 - ♦ avoid conditions that promote sickling (hypoxia, acidosis, dehydration, fever)
 - ♦ vaccination in childhood (pneumococcus, meningococcus, H. influenzae b)
 - ♦ prophylactic penicillin (age 3 mo-5 yr)
 - ♦ good hygiene, nutrition, and social support
 5. screen for complications
 - ♦ regular blood work (CBC, reticulocytes, iron indices, BUN, LFTs, creatinine)
 - ♦ urinalysis annually (proteinuria, glomerulopathy)
 - ♦ transcranial doppler annually until 16 yr old (stroke prevention)
 - ♦ retinal examinations annually from 8 yr old (screen for retinopathy)
 - ♦ echocardiography once in late childhood/early adulthood (screen for pulmonary hypertension)

Organs Affected by Vaso-Occlusive Crisis

Organ	Problem
Brain	Ischemic or hemorrhagic stroke, vasculopathy
Eye	Hemorrhage, blindness
Liver	Infarcts, RUQ syndrome
Lung	Chest syndrome, long-term pulmonary hypertension
Gallbladder	Stones
Heart	Hyperdynamic flow murmurs
Spleen	Enlarged (child); atrophic (adult)
Kidney	Hematuria, loss of renal concentrating ability, proteinuria
Intestines	Acute abdomen
Placenta	Stillbirths
Penis	Priapism
Digits	Dactylitis
Femoral and Humeral Head	Avascular necrosis
Bone	Infarction, infection
Ankle	Leg ulcers

NIH Consensus Development Conference Statement: Hydroxyurea Treatment for Sickle Cell Disease

Ann Intern Med 2008;148:932-938

Efficacy: Strong evidence for adolescents and adults and there is emerging data supporting its use in children. In the single RCT, the Hb level was higher in hydroxyurea recipients than placebo recipients after 2 yr (difference, 6 g/L), as was HbF (absolute difference, 3.2%). The median number of painful crises was 44% lower than in the placebo arm. The 12 observational studies that enrolled adults reported a relative increase in HbF of 4-20% and a relative reduction in crisis rates by 68-84%. Hospital admissions declined by 18-32%.

Effectiveness: Data is limited. It seems to be highly effective but is currently underutilized.

Short-Term Harms (within 6 mo): Dose-related leukopenia, thrombocytopenia, anemia, and decreased reticulocyte count. Others include decreased sperm production and dry skin.

Long-Term Harms: Birth defects in offspring of people receiving the drug, growth delays in children receiving the drug, and cancer in both children and adults who receive the drug.

Autoimmune Hemolytic Anemia

Table 14. Classification of AIHA

	Warm (75-90% cases)	Cold
Antibody Allotype	IgG	IgM
Agglutination Temperature	37°C	4-37°C
Direct Coombs Test (direct anti-globulin test)	Positive for IgG ± complement	Positive for complement
Etiology	Idiopathic Secondary to lymphoproliferative disorder (e.g. CLL, Hodgkin lymphoma) Secondary to autoimmune disease (e.g. SLE) Drug-induced (e.g. penicillin, quinine, methyl dopa)	Idiopathic Secondary to infection (e.g. mycoplasma pneumonia, EBV) Secondary to lymphoproliferative disorder (e.g. macroglobulinemia, CLL)
Blood Film	Spherocytes	Agglutination
Management	Treat underlying cause Corticosteroids Immunosuppression Splenectomy Folic acid Rituximab (2nd line to steroids)	Treat underlying cause Warm patient/avoid cold Rituximab regimens (1st line) Plasma exchange (2nd line for high IgM levels) Folic acid Low dose alkylating agents (chlorambucil, cyclophosphamide) or interferon may be useful but less effective

Microangiopathic Hemolytic Anemia Thrombotic Microangiopathy

Definition

- hemolytic anemia due to intravascular fragmentation of RBCs

Etiology

- see *Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome, H30*
- see *Disseminated Intravascular Coagulation, H32*
- eclampsia, HELLP syndrome, AFLP (see *Obstetrics, OB25*)
- malignant hypertension
- vasculitis
- malfunctioning heart valves
- metastatic carcinoma
- drugs (calcineurin inhibitors, quinine, simvastatin)
- infections (severe CMV or meningococcus)
- catastrophic antiphospholipid antibody syndrome

Investigations

- blood film: evidence of hemolysis, schistocytes
- hemolytic workup
- urine: hemosiderinuria, hemoglobinuria

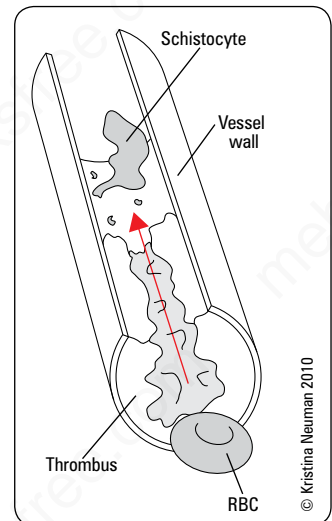

Figure 8. Schistocyte

Hereditary Spherocytosis

- most common type of hereditary hemolytic anemia
- abnormality in RBC membrane proteins (e.g. spectrin)
 - spleen makes defective RBCs more spherocytotic (and more fragile) by membrane removal; also acts as site of RBC destruction
- autosomal dominant with variable penetrance

Investigations

- blood film (shows spherocytes), osmotic fragility (increased), molecular analysis for spectrin gene

Treatment

- in severe cases, splenectomy and vaccination against pneumococcus, meningococcus, and *H. influenzae* b (avoid in early childhood)

Hereditary Elliptocytosis

Definition/Etiology

- abnormality in spectrin interaction with other membrane proteins
- autosomal dominant
- 25-75% elliptocytes
- hemolysis is usually mild

Treatment

- immunizations; splenectomy for severe hemolysis

Glucose-6-Phosphate Dehydrogenase Deficiency

Definition

- deficiency in glucose-6-phosphate dehydrogenase (G6PD), corresponding to a lack of reduced glutathione (GSH) and leading to RBC sensitivity due to oxidative stress

Pathophysiology

- X-linked recessive, prevalent in individuals of African, Asian, and Mediterranean descent

Clinical Features

- frequently presents as episodic hemolysis precipitated by:
 - oxidative stress
 - drugs (e.g. sulfonamide, antimalarials, nitrofurantoin)
 - infection
 - food (fava beans)
- in neonates: can present as prolonged, pathologic neonatal jaundice

Investigations

- neonatal screening
- G6PD assay (may not be useful if result is normal)
 - should not be done in acute crisis when reticulocyte count is high (reticulocytes have high G6PD levels)
- blood film
 - Heinz bodies (granules in RBCs due to oxidized Hb); passage through spleen results in the generation of bite cells
 - may have features of intravascular hemolysis (e.g. RBC fragments)

Treatment

- folic acid
- stop offending drugs and avoid triggers
- transfusion in severe cases

Macrocytic Anemia

- MCV >100 fL
- see Figure 2, Approach to Anemia, H6

Table 15. Comparison Between Megaloblastic and Non-Megaloblastic Macrocytic Anemia

	Megaloblastic	Non-Megaloblastic
Morphology	Large, oval, nucleated RBC precursor Hypersegmented neutrophils	Large round RBC Normal neutrophils
Pathophysiology	Failure of DNA synthesis resulting in asynchronous maturation of RBC nucleus and cytoplasm	Reflects membrane abnormality with abnormal cholesterol metabolism

Figure 9. Spherocytosis secondary to AIHA

Figure 10. G6PD deficiency

Causes of Macrocytic Anemia

- ABCDEF**
- Alcoholism (liver disease)
 - B₁₂ deficiency
 - Compensatory reticulocytosis
 - Drugs (cytotoxic, AZT)/Dysplasia
 - Endocrine (hypothyroidism)
 - Folate deficiency/Fetus (pregnancy)

Characteristics of Megaloblastic Macrocytic Anemia

- Pancytopenia
- Hypersegmented neutrophils
- Megaloblastic bone marrow

Vitamin B₁₂ Deficiency

- B₁₂ (cobalamin) see **Family Medicine, Nutrition, FM6**
- binds to intrinsic factor (IF) secreted by gastric parietal cells
- absorbed in terminal ileum
- total body stores sufficient for 3-4 yr

Etiology

Table 16. Etiology of Vitamin B₁₂ Deficiency

Diet	Gastric	Intestinal Absorption	Genetic
Strict vegan More likely to present in pediatric population Vegetarian in pregnancy Malnutrition	Mucosal atrophy Gastritis, autoimmune Pernicious anemia (see below) Post-gastrectomy	Malabsorption Crohn's, celiac sprue, pancreatic insufficiency, <i>H. pylori</i> Stagnant bowel Blind loop, stricture Fish tapeworm Resection of ileum Drugs Neomycin, biguanides, PPI, N ₂ O anesthesia, metformin	Transcobalamin II deficiency IF receptor defect

Pathophysiology of Pernicious Anemia

- auto-antibodies produced against gastric parietal cells leading to achlorhydria and lack of intrinsic factor secretion
- intrinsic factor is required to stabilize B₁₂ as it passes through the bowel
- decreased intrinsic factor leads to decreased ileal absorption of B₁₂
- may be associated with other autoimmune disorders (polyglandular endocrine insufficiency)
- most common in Northern European Caucasians, usually >30 yr old (median age of 60 yr old)

Clinical Features

- neurological (severity of anemia and neurological sequelae depends on deficiency)
 - peripheral neuropathy (variable reversibility)
 - ♦ usually symmetrical, affecting lower limbs more than upper limbs
 - cord (irreversible damage)
 - ♦ subacute combined degeneration
 - posterior columns: decreased vibration sense, proprioception, and 2-point discrimination, parasthesia
 - pyramidal tracts: spastic weakness, ataxia
 - cerebral (common, reversible with B₁₂ therapy)
 - ♦ confusion, delirium, dementia
 - cranial nerves (rare)
 - ♦ optic atrophy

Investigations

- CBC, reticulocyte count
 - anemia often severe ± neutropenia ± thrombocytopenia
 - MCV >110 fL
 - low reticulocyte count relative to the degree of anemia (<2%)
- serum B₁₂ and RBC folate
 - caution: low serum B₁₂ leads to low RBC folate because of failure of folate polyglutamate synthesis in the absence of B₁₂
 - alternatively, can measure elevated urine metabolites (methylmalonate, homocysteine)
- blood film
 - oval macrocytes, hypersegmented neutrophils
- bone marrow
 - hypercellularity
 - nuclear-cytoplasmic asynchrony in RBC precursors (less mature nuclei than expected from the development of the cytoplasm)
- bilirubin and LDH
 - elevated unconjugated bilirubin and LDH due to breakdown of cells in BM
- Schilling test (radiolabeled B₁₂ test, rarely done) to distinguish pernicious anemia from other causes
 - anti-intrinsic factor antibody, anti-parietal cell antibody

Treatment

- vitamin B₁₂ 1,000 µg IM or 1,000-1,200 µg PO if intestinal absorption intact, route and duration depends on cause
- less frequent, higher doses may be as effective (e.g. 1,000 µg IM q3mo)
- watch for hypokalemia and rebound thrombocytosis when treating severe megaloblastic anemia

Oral Vitamin B₁₂ vs. Intramuscular Vitamin B₁₂ for Vitamin B₁₂ Deficiency

Cochrane DB Syst Rev 2005;3:CD004655

Study: Systematic review. 2 RCTs met inclusion criteria; total 108 patients with follow-up from 90 d-4 mo.

Intervention: One study evaluated 1,000 µg of oral B₁₂ compared to 1,000 µg IM B₁₂ on the same dosing schedule. The other compared 2,000 µg daily oral B₁₂ to 1,000 µg IM B₁₂ on a less frequent dosing schedule. Neurological and hematological end points were evaluated.

Results: Meta-analysis was not attempted due to study heterogeneity. Both studies reported improvements in hematological and neurological end-points in both oral and IM groups. No significant difference was observed between groups in either study.

Conclusions: Limited data suggests high dose oral vitamin B₁₂ (1,000-2,000 µg) is equivalent to IM vitamin B₁₂ on the same or less frequent dosing schedule. This data is limited by small sample sizes and short follow-up periods. However, it suggests that a 3 to 4 month trial of oral supplementation is a reasonable first choice for patients with B₁₂ deficiency.

Schilling Test

Part 1

- Tracer dose (1 µg) of radiolabeled B₁₂, given PO
- Flushing dose (1 mg) of unlabeled B₁₂ IM 1 h later to saturate tissue binders of B₁₂ thus allowing radioactive B₁₂ to be excreted in urine
- 24 h urine radiolabeled B₁₂ measured
- Normal >5% excretion (a normal excretion will only be seen if the low B₁₂ was due to dietary deficiency)

Part 2

- Same as part 1, but radiolabeled B₁₂ given with oral intrinsic factor
- Should be done only if first stage shows reduced excretion
- Normal test result (>5% excretion) = pernicious anemia
- Abnormal test result (<5% excretion) = intestinal causes (malabsorption)

Folate Deficiency

- uncommon in developed countries due to extensive dietary supplementation (enriched in flour)
- folate stores are depleted in 3-6 mo
- folate commonly found in green, leafy vegetables and fortified cereals

Etiology

Table 17. Etiology of Folate Deficiency

Diet/Deficiency	Malabsorption	Drugs	Increased Demand
Alcoholism	Celiac sprue	Anti-folates (methotrexate)	Pregnancy
Substance abuse	IBD	Anticonvulsants (phenytoin)	Hemolysis
Elderly/infants	Infiltrative bowel disease	Alcohol	Prematurity
Poor intake	Short bowel syndrome	Oral contraceptive	Exfoliative dermatitis/psoriasis
			Hemodialysis

Clinical Features

- anemia, mild jaundice, glossitis, diarrhea, confusion, pallor
- unlike B₁₂ deficiency, folate deficiency has no neurologic manifestations
- consider social history, alcohol/drug abuse, very poor diet (e.g. elderly, depressed)

Investigations

- similar to B₁₂ deficiency (CBC, reticulocytes, blood film, RBC folate, serum B₁₂)
- if decreased RBC folate, rule out B₁₂ deficiency as cause

Management

- folic acid 1-5 mg PO OD x 1-4 mo; then 1 mg PO OD maintenance if cause is not reversible

Never give folate alone to an individual with megaloblastic anemia because it will mask B₁₂ deficiency and neurological degeneration will continue

Hemostasis

Stages of Hemostasis

1. Primary Hemostasis

- cellular defense – involves the platelet and vWF predominantly
- goal is rapid cessation of bleeding; main effect is on mucocutaneous bleeding
- vessel injury results in collagen/subendothelial matrix exposure and release of vasoconstrictors
- blood flow is impeded and platelets come into contact with damaged vessel wall (Figure 11a)
 - adhesion: platelets adhere to subendothelium via von Willebrand factor (vWF)
 - activation: platelets are activated resulting in change of shape and release of ADP and thromboxane A₂
 - aggregation: these factors further recruit and aggregate more platelets resulting in formation of localized hemostatic plug

2. Secondary Hemostasis

- platelet plug is reinforced by production of fibrin clot (Figure 11b)
- extrinsic (initiation) pathway: initiation of coagulation in vivo
- intrinsic (amplification) pathway: amplification once coagulation has started via positive feedback
- both intrinsic and extrinsic pathways converge onto the common pathway which results in thrombin generation and fibrin formation

3. Fibrin Stabilization

- conversion from soluble to insoluble and stable clot

4. Fibrinolysis

- once healing initiated, clot dissolution via action of the fibrinolytic system

Normal hemostasis occurs as a result of the balance between procoagulant and anticoagulant factors

Phases of Hemostasis

- **Primary hemostasis**
Vascular response and platelet plug formation via vWF
- **Secondary hemostasis**
Fibrin clot formation
- **Fibrin stabilization**
Fibrinolysis

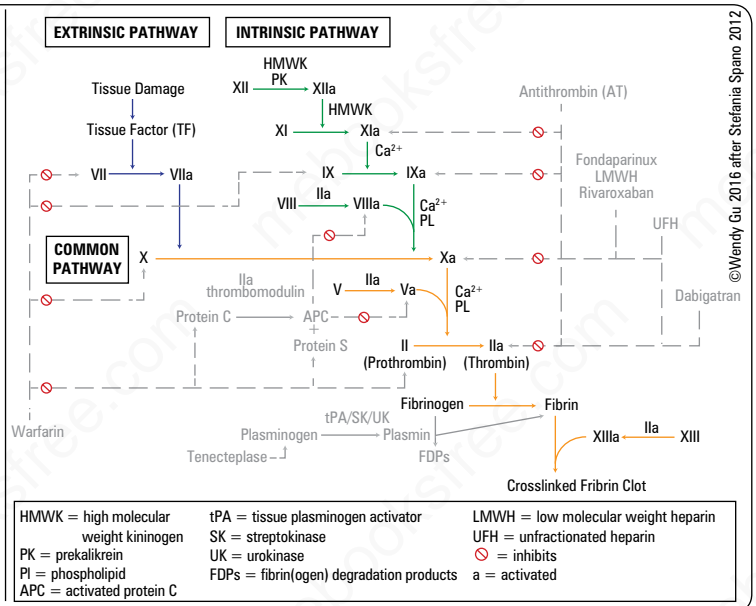

Figure 11a. Platelet activation cascade

Figure 11b. Coagulation cascade

Table 18. Commonly Used Tests of Hemostasis

Type of Hemostasis	Test	Reference Range	Purpose	Examples of Associated Diagnoses
Primary	Platelet count	150-400 x 10 ⁹ /L	To quantitate platelet number	Low in ITP, HUS/TTP, DIC
Secondary	aPTT	22-35 s	Measures intrinsic pathway (factors VIII, IX, XI, XII) and common pathway Used to monitor heparin therapy	Prolonged in hemophilias A and B (if factor deficiency is below reagent threshold of detection) N.B. High if antiphospholipid antibodies (i.e. lupus anti-coagulant) are present
	PT	11-24 s	Measures extrinsic pathway (factor VII) and common pathway	Prolonged in vitamin K deficiency, vitamin K antagonist therapy (warfarin), factor VII deficiency
	INR	0.9-1.2	Used to monitor warfarin therapy and for assessment of hepatic function	
	Mixing studies		May differentiate inhibitors of clotting factor(s) from a deficiency in clotting factors Mix patient's plasma with normal plasma in 1:1 ratio and repeat abnormal test	Normalization of clotting time if deficiency of single clotting factor (normalization may not occur if multiple clotting factors are deficient) Lack of normalization if inhibitor presence
Fibrinolysis	Euglobulin lysis time	N > 90 min	Looks for accelerated fibrinolysis	May be accelerated in DIC or factor XIII deficiency Decreased in hereditary deficiency of fibrinogen
Other	Fibrinogen D-dimer Specific factor assays (e.g. factor VIII) Lupus anticoagulant Thrombophilia tests (e.g. activated protein C resistance) von Willebrand tests (vWF antigen, Ristocetin cofactor activity, factor VIII)			

Tests of Secondary Hemostasis

PT/INR: Tennis is played outside (Extrinsic pathway)
 PTT: Table Tennis is played inside (Intrinsic pathway)

Figure 12. Clotting factors involved in PT and PTT

Causes of an Prolonged PTT Without Bleeding include:

1. Early contact factor (Factor XII, HMWK, PK) deficiency
2. Lupus anticoagulant
3. Inappropriate blood draw
4. Heparin contamination
5. Erythrocytosis (laboratory artifact)

Table 19. General Rules of Thumb: Signs and Symptoms of Disorders of Hemostasis

	Primary (Platelet, vWF)	Secondary (Coagulation)
Surface Cuts	Excessive, prolonged bleeding	Normal/slightly prolonged bleeding
Onset After Injury	Immediate	Delayed
Site of Bleeding	Superficial i.e. mucosal (nasal, gingival, GI tract, vaginal), skin	Deep i.e. joints, muscles Excessive post-traumatic vaginal)
Lesions	Petechiae, ecchymoses	Hemarthroses, hematomas

Consider PTT

- IV heparin, argatroban monitoring
- Hemophilia A/B, factor XI deficiency, severe vWF

Table 20. Lab Values in Disorders of Hemostasis

	PT	PTT	Platelet Count	Hemoglobin
Hemophilia A/B	N	↑	N	N*
vWD	N	±	N/↓	N*
DIC	↑	↑	↓	N/↓
Liver Failure	↑	N/↑	N/↓	N
ITP	N	N	↓	N
TTP	N	N	↓	↓

DIC = disseminated intravascular coagulation; ITP = idiopathic thrombocytopenic purpura; TTP = thrombotic thrombocytopenic purpura; vWD = von Willebrand disease; * = anemia may develop from progressive iron deficiency and/or active bleeding

Consider PT/INR

- Warfarin
- Liver disease
- Risk factor for vitamin K deficiency (e.g. malabsorption, cholestasis, malnutrition)

Consider both PTT and PT/INR

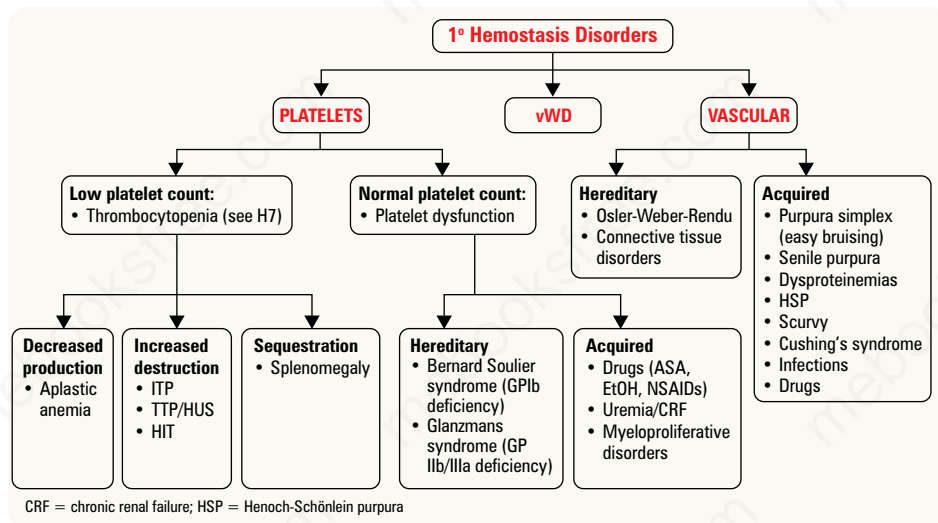

- Suspected DIC
- Trauma patient, or requiring massive transfusion protocol
- Bleeding patient
- Patient receiving thrombolytic therapy

Disorders of Primary Hemostasis

Definition

- inability to form an adequate platelet plug due to
 - disorders of blood vessels
 - disorders of platelets: abnormal function/numbers
 - disorders of vWF

Classification

CRF = chronic renal failure; HSP = Henoch-Schönlein purpura

Figure 13. Approach to disorders of primary hemostasis

Immune Thrombocytopenia

Table 21. Features for Childhood vs. Adult Immune Thrombocytopenia

Features	Childhood ITP, see Pediatrics, P61	Adult ITP
Peak Age	2-6 yr	20-40 yr
Gender	None	F>M (3:1)
History of Recent Infection	Common	Rare
Onset of Bleed	Abrupt	Insidious
Duration	Usually wk	Mo to yr
Spontaneous Remissions	80% or more	Uncommon

Terminology of ITP

- primary: isolated thrombocytopenia (platelet count <100x 10⁹/L) with no other cause of thrombocytopenia
- secondary: thrombocytopenia associated with another condition (e.g. HIV, HCV, SLE, CLL)
- drug-induced: drug-dependent platelet antibodies causing platelet destruction

Drugs Associated with Thrombocytopenia

TMP-SMX	Heparin	NSAIDs
Vancomycin	Digoxin	Acetaminophen
Rifampin	Amiodarone	Ethanol
Ethambutol	Quinidine	H ₂ -antagonists
Amphotericin B	Quinine	

Classification of primary ITP

- acute: newly diagnosed (diagnosis to 3 mo)
- persistent: 3-12 mo from diagnosis
- chronic: >12 mo
- refractory: post-splenectomy

Pathophysiology

- primary or secondary ITP
- an acquired immune-mediated disorder (pathophysiology incompletely understood)
 - anti-platelet antibodies bind to platelet surface → increased splenic clearance
 - impaired platelet production
 - helper T-cell and cytotoxic T-cell activation also implicated in platelet destruction

Clinical Presentation

- variable presentation: asymptomatic, fatigue, minimal bruising, mucocutaneous bleed, intracranial bleed
- assess for symptoms/signs suggesting a secondary cause

Investigations

- CBC and reticulocyte count: thrombocytopenia
- PT and aPTT: normal
- peripheral blood film: decreased platelets, giant platelets (rule out platelet clumping)
- HIV, HCV, *H. pylori* serology
- vitamin B₁₂, ANA, C3, C4, depending on clinical symptoms
- bone marrow aspirate and biopsy: increased number of megakaryocytes
 - recommended in patients >60 yr of age, pre-splenectomy or have failed traditional ITP therapy, those with systemic symptoms, an abnormal blood film
 - bone marrow aspirate and biopsy should be considered if there is any suspicion of diminished bone marrow function (e.g. myelodysplasia, infiltration)

Treatment

- rarely indicated if platelets >30 x 10⁹/L unless active bleeding, trauma, or surgery
- emergency treatment (active bleeding [CNS, GI, or GU] or in need of emergency surgery)
 - general measures: stop drugs that reduce platelet function, control blood pressure, minimize trauma
 - corticosteroids: prednisone (1 mg/kg) or dexamethasone (40 mg PO x 4 d)
 - antifibrinolytic: tranexamic acid (1 g PO tid or 1 g IV q6h) if mucosal bleeding
 - IVIg 1 g/kg/d x 2 doses
 - platelet transfusion: for refractory, major bleeding or need for urgent surgery (expect that platelet recovery will be diminished)
 - emergency splenectomy: may be considered, vaccinations prior if possible (pneumococcus, meningococcus, *H. influenzae* b)
 - management of intracranial bleeding: IV steroids, IVIg, platelets
- non-urgent treatment (platelet count <20-30 x 10⁹/L and no bleeding)
 - 1st line
 - ♦ corticosteroids (dexamethasone 40 mg qd x 4 d x 1-4 cycles (not wk) or prednisone x 3 wk then taper)
 - ♦ IVIg
 - ♦ anti-D: appropriate for Rh+ non-splenectomized patients, but can cause hemolysis (avoid if low Hb at baseline or if DAT is positive)
 - 2nd line
 - ♦ splenectomy (need vaccinations prior to splenectomy: pneumococcus, meningococcus, *H. influenzae* b)
 - ♦ rituximab
 - 3rd line
 - ♦ thrombopoietin (TPO) receptor agonists (romiplostim, eltrombopag) – may be considered for second line therapy if funding available
 - ♦ immunomodulating therapy (azathioprine, cyclophosphamide, danazol, vincristine)

Definitions of Response to Treatment

- complete response: platelet >100
- partial response: platelet 30-100
- no response: platelet <30

Prognosis

- ~20% will not attain a hemostatic platelet count after first and second line therapy
- fluctuating course
- overall relatively benign, life-expectancy similar to general population (however, risk of mortality from bleeding/infection increases with advancing age)
- major concern is spontaneous intracranial hemorrhage if platelet <5 x 10⁹/L, more common in the elderly

Mechanisms for HIV-associated Thrombocytopenia

- Direct effect of HIV on marrow
- Immune-mediated platelet destruction
- Some anti-retrovirals reduce platelet production

Table 22. Heparin-Induced Thrombocytopenia (HIT)

Pathophysiology	Immune mediated Ab recognizes a complex of heparin and platelet factor 4 (PF4) leading to platelet activation via platelet Fc receptor and activation of coagulation system
Diagnosis	Suspected with intermediate or high probability HIT Score (Table 23) Confirm with ELISA testing and SRA testing
Onset of Decreased Platelets	5-15 d (if previously exposed to heparin within 100 d, HIT can develop in hours due to an anamnestic response)
Risk of Thrombosis	~30% to 50% (25% of events are arterial)
Clinical Features	Bleeding complications uncommon Venous thrombosis: DVT, PE, limb gangrene, cerebral sinus thrombosis Arterial thrombosis: MI, stroke, acute limb ischemia, organ infarct (mesentery, kidney) Heparin-induced skin necrosis (with LMWH) Acute platelet activation syndromes: acute inflammatory reactions (e.g. fever/chills, flushing, etc.) Transient global amnesia (rare)
Specific Tests	Re-test clinical scoring models can help rule-out HIT: 4-Ts (see Table 23) and the HIT Expert Probability (HEP) score 14C serotonin release assay (uses donor platelets with 14C serotonin and heparin with patient's plasma) ELISA for HIT-Ig (more sensitive, less specific than serotonin assay) Ultrasound of lower limb veins for DVT
Management	Clinical suspicion of HIT should prompt discontinuation of heparin and LMWH (specific tests take several days) Initiate anticoagulation with a non-heparin anticoagulant: e.g. argatroban, danaparoid, fondaparinux, bivalirudin unless there is a strong contraindication (duration of treatment at least 2-3 mo if no thrombotic event, and at least 3-6 mo if thrombotic event has occurred) Warfarin should only be restarted when platelet count > 150 x 10 ⁹ /L Allergy band and alert in patient records

Table 23. The 4-T Pre-Test Clinical Scoring Model for HIT

Category	2 Points	1 Point	0 Points
1. Thrombocytopenia	Platelet count fall >50% AND platelet nadir $\geq 20 \times 10^9/L$	Platelet count fall 30-50% OR platelet nadir $10-19 \times 10^9/L$	Platelet count fall <30% OR platelet nadir $< 10 \times 10^9/L$
2. Timing of Platelet Count Fall	Clear onset between 5-10 d of heparin exposure OR platelet count fall at ≤ 1 d if prior heparin exposure within last 30 d	Consistent with fall in platelet count at 5-10 d but unclear (e.g. missing platelet counts) OR onset after day 10 OR fall ≤ 1 d with prior heparin exposure within 30-100 d	Platelet count fall after <4 d of heparin exposure, and no recent heparin
3. Thrombosis or Other Sequelae	Confirmed new thrombosis, skin necrosis, or acute systemic reaction after IV unfractionated heparin bolus	Progressive or recurrent thrombosis, non-necrotizing (erythematous) skin lesions, or suspected thrombosis that has not been proven	None
4. Other Causes for Thrombocytopenia	None apparent	Possible	Definite

6-8 points = high probability of HIT; 4-5 points = intermediate probability of HIT; 0-3 points = low probability of HIT
J Thromb Haemos 2006;4:759-765

**Heparin-Induced Thrombocytopenia**

- Heparin-induced thrombocytopenia (previously known as HIT type II): immune-mediated reaction following treatment with heparin leading to platelet and subsequent coagulation activation
- Heparin-associated thrombocytopenia (previously known as HIT type I): transient thrombocytopenia following administration of heparin

**Heparin-Associated Thrombocytopenia (previously known as HIT type I)**

- Direct heparin mediated platelet aggregation (non-immune)
- Platelets $> 100 \times 10^9/L$
- Self-limited (no thrombotic risk)
- May continue with heparin therapy
- Onset 24-72 h

LMWH is also associated with HIT, but the risk is less than unfractionated heparin (2.6% in UFH vs. 0.2% in LMWH)

Thrombotic Thrombocytopenic Purpura and Hemolytic Uremic Syndrome

Table 24. TTP and HUS

	TTP	HUS (see Pediatrics, P71)
Epidemiology	Predominantly adult	Predominantly children and elderly
Etiology	Deficiency of metalloproteinase that breaks down ultra-large vWF multimers: ADAMTS13 Congenital (genetic absence of ADAMTS-13) Acquired (drugs, malignancy, transplant, HIV-associated, idiopathic)	Shiga toxin (<i>E. coli</i> serotype O157:H7) in 90% Other bacteria, viruses, genetic causes, drugs
Clinical Features	1. Thrombocytopenia 2. MAHA/TMA 3. Neurological symptoms: headache, confusion, focal defects, seizures 4. Symptoms can be mild and non-specific	1. Severe thrombocytopenia 2. MAHA/TMA 3. Acute kidney injury 4. Bloody Diarrhea 5. GI prodrome
Investigations (both TTP, HUS)	CBC and blood film: decreased platelets and schistocytes PT, aPTT, fibrinogen: normal Markers of hemolysis: increased unconjugated bilirubin, increased LDH, decreased haptoglobin Negative Coombs test Creatinine and urea to follow renal function ADAMTS-13 gene, activity or inhibitor testing (TTP)	
Management	Medical emergency Plasma exchange ± steroids Platelet transfusion avoided unless life-threatening bleed (associated with microvascular thrombosis) Plasma infusion if plasmapheresis is not immediately available TTP mortality ~90% if untreated	Supportive therapy (fluids, RBC transfusion, nutrition, etc.) Some evidence for plasma exchange Possible role of Eculizumab (C5 antibody blocks complement activation) for neurologic symptoms

Note: atypical HUS is a complex disease with different etiology, treatment depends on genetic abnormalities

Pathophysiology of TTP

- Large vWF multimers secreted by endothelial cells are typically rapidly cleaved by ADAMTS-13 protease
- Congenital TTP is due to a genetic deficiency in ADAMTS-13
- Antibodies against ADAMTS-13 are present in acquired TTP (the more common form)

Differential Diagnosis of TTP

- DIC
- HUS
- aHUS
- HELLP
- Catastrophic antiphospholipid Ab syndrome
- Evans syndrome (AIHA + TTP)

von Willebrand Disease

Pathophysiology

- most common inherited bleeding disorder (prevalence of 1%)
- usually autosomal dominant (type 3 is autosomal recessive)
- women more commonly diagnosed (heavy menstrual bleeding, peripartum bleeding)
- qualitative defect or quantitative deficiency of vWF depending on type
 - vWF needed for platelet adhesion/aggregation and acts as chaperone for Factor VIII (extending its half-life in circulation), therefore abnormality of vWF can affect both primary and secondary hemostasis
 - vWF exists as a series of multimers ranging in size
 - ♦ largest multimers are most active in mediation of platelet adhesion/aggregation
 - ♦ both large and small multimers complex with Factor VIII
 - ♦ vWF levels vary according to blood group (non-group O patients have higher levels than group O patients)

Classification

- type 1: mild quantitative defect (decreased amount of vWF and proportional decrease in vWF activity) – 80% of cases
- type 2: qualitative defect (vWF activity disproportionately lower than quantity) – 20% of cases
- type 3: severe total quantitative defect (virtually no vWF produced), 1 per million

Clinical Features

- bleeding history is the single most important predictor of an underlying bleeding disorder
- validated, standardized bleeding assessment tools (e.g. ISTH-BAT) to facilitate exploration of the bleeding history
- mucocutaneous bleeding (easy bruising, epistaxis, heavy menstrual bleeding, peripartum bleeding, post-dental extraction bleeding, post-operative bleeding, gastrointestinal bleeding)
 - type 3 vWD patients can experience musculoskeletal bleeding due to significant deficiency in FVIII due to lack of FVIII chaperoning as vWF is absent

Investigations

- CBC, platelet, vWF:Antigen (determine how much vWF is present), vWF:Ristocetin cofactor activity (determine how well vWF bind to platelet), Factor VIII (determine how well vWF chaperone with FVIII), PTT
- tests to further categorize type/subtype of vWD: multimer analysis, ristocetin induced platelet agglutination, genetic studies

Table 25. Investigations in vWD

Test	Expected Result	Test	Expected Result
PTT	N/↑	von Willebrand antigen	↓
Factor VIII	N/↓	Blood group	Affects antigen quantification (↓ in group O)
Plt Count	N/↓	vWF multimer analysis	Multimer variants
Ristocetin Activity	↓ (cofactor for vWF-Plt binding)		

Treatment

- desmopressin (DDAVP[®]) is effective treatment for 85-90% of patients with type 1 vWD and for some subtypes of type 2 vWD
 - causes release of vWF and Factor VIII from endothelial cells
 - variable efficacy depending on disease type; tachyphylaxis occurs after 4 consecutive doses
 - need to document responsiveness with "DDAVP challenge"
 - caution in children due to hyponatremia
- tranexamic acid (Cyklokapron[®], antifibrinolytic) to stabilize clot formation
- vWF: FVIII concentrate (Humate P[®], Wilate[®]) if DDAVP unresponsive/clinically ineffective or for severe bleeding episode
 - need to monitor vWF and factor VIII levels (very high factor VIII level can be prothrombotic)
- gynecologic focused care for heavy menstrual bleeding (NB estrogens have the added benefit of increasing vWF levels)

Prognosis

- patients with mild type 1 vWD have auto-correction of vWF deficiency in pregnancy
- patients are best managed by a hematologist, ideally one who works in a Hemophilia Treatment Centre (HTC)

Consider vWD in all women with menorrhagia

vWD is the most common inheritable coagulation abnormality

Disorders of Secondary Hemostasis

Definition

- inability to form an adequate fibrin clot
 - disorders of clotting factors or co-factors
 - disorders of proteins associated with fibrinolysis
- characterized by delayed bleeding, deep muscular bleeding, spontaneous hemarthroses

Table 26. Classification of Secondary Hemostasis Disorders

Hereditary	Acquired
Factor VIII: Hemophilia A, vWD	Liver disease
Factor IX: Hemophilia B (Christmas Disease)	DIC
Factor XI	Vitamin K deficiency
Other factor deficiencies are rare	Acquired inhibitors (FVIII most common)

Hemophilia A (Factor VIII Deficiency)

Pathophysiology

- X-linked recessive, 1/5,000 males
- mild (>5% of normal factor level), moderate (1-5%), severe (<1%)

Clinical Features

- see Table 19 – *Signs and Symptoms of Disorders of Hemostasis, H26*
- older patients may also have HIV or HCV from contaminated blood products

Investigations

- prolonged aPTT, normal INR (PT)
- decreased Factor VIII (<40% of normal)

Treatment

- desmopressin (DDAVP[®]) in mild hemophilia A
- Factor VIII concentrate for
 - prophylaxis
 - on-demand (i.e. to treat a bleed)
- anti-fibrinolytic agents (e.g. tranexamic acid)

Hemophilia B (Factor IX Deficiency)

- X-linked recessive, 1/30,000 males; approximately half have severe disease (factor IX activity <1% of normal)
- clinical and laboratory features identical to hemophilia A (except decreased Factor IX)
- treatment: Factor IX concentrate (prophylaxis or on-demand), anti-fibrinolytic agents

Factor XI Deficiency

- autosomal recessive; more common in Ashkenazi Jewish population
- usually mild, often diagnosed in adulthood
- Factor XI level does not correlate with bleeding risk – risk of bleeding correlates with a previous history or family history of bleeding
- treatment: antifibrinolytic agents, frozen plasma, Factor XI concentrate

Liver Disease

- see [Gastroenterology, G32](#)

Pathophysiology

- deficient synthesis of all factors except VIII (also made in endothelium)
- aberrant or diminished synthesis of fibrinogen (factor I)
- diminished synthesis of natural anticoagulants and altered regulation of fibrinolysis

Investigations

- peripheral blood film: target cells
- primary hemostasis affected
 - thrombocytopenia 2° to hypersplenism, nutritional deficiency, direct bone marrow toxicity related to alcohol, diminished production from chronic viral infections (e.g. HCV), decreased production of thrombopoietin
- secondary hemostasis affected
 - elevated INR (PT), aPTT and TT, low fibrinogen in end-stage liver disease

Treatment

- supportive, treat liver disease, blood products if active bleeding (frozen plasma, platelets, cryoprecipitate)

Investigations in Liver Disease

Factor V, VII, VIII. Expect decreased V and VII because they have the shortest half-life. Factor VIII will be normal or increased because it is produced in the endothelium

Vitamin K Dependent Factors

Vitamin K antagonists (e.g. warfarin) affect function of these factors:
"1972 Canada vs. Soviets"
X, IX, VII, II proteins C and S

PT should improve within 24 h of adequately dosed vitamin K repletion (onset is in 6-12 h); if not, search for other causes

American Society of Hematology Choosing Wisely Recommendation

Do not administer plasma or prothrombin complex concentrates for non-emergent reversal of vitamin K antagonists (e.g. outside of the setting of major bleeding, intracranial hemorrhage, or anticipated emergent surgery)

DIC is a spectrum which may include thrombosis, bleeding, or both

Factor Levels in Acquired Coagulopathies

Factor	Liver Disease	Vitamin K Def	DIC
V	↓	N	↓
VII	↓	↓	↓
VIII	N/↑	N	↓

Vitamin K Deficiency

Etiology

- drugs
 - vitamin K antagonist (e.g. Warfarin) – diminished production of functional Factors II, VII, IX, X, proteins C and S
 - antibiotics eradicating gut flora, altering vitamin K uptake
- poor diet (especially in alcoholics) e.g. prolonged fasting or starvation
- biliary obstruction
- chronic liver disease (decreased stores)
- fat malabsorption (e.g. celiac disease, disorders of bile or pancreatic secretion, intestinal disease, CF)
- hemorrhagic disease of newborn, see [Pediatrics, P42](#)

Investigations

- INR (PT) is elevated out of proportion to elevation of the aPTT
- decreased Factors II, VII, IX, X (vitamin K-dependent)

Treatment

- hold anticoagulant if vitamin K antagonist on board
- vitamin K PO if no active bleeding
- if bleeding, give vitamin K 10 mg IV (reversal may take up to 12 h)
- if life-threatening bleeding and vitamin K antagonist used, give prothrombin complex concentrate (PCC) or FP if PCC contraindicated
 - PCCs are contraindicated if there is a previous history of HIT (heparin is within the PCC product)

Disseminated Intravascular Coagulation

Definition

- excessive, dysregulated release of plasmin and thrombin leading to intravascular coagulation and depletion of platelets, coagulation factors and fibrinogen
- risk of life-threatening hemorrhage or thromboembolism

Etiology

- occurs as a complication of many other severe medical, surgical or obstetrical conditions
- widespread endothelial damage and extensive inflammatory cytokine release

Table 27. Etiology of DIC

Activation of Procoagulant Activity	Endothelial Injury	Reticuloendothelial Injury	Vascular Stasis	Other
Antiphospholipid antibody syndrome (APS)	Infections/sepsis Vasculitis	Liver disease Splenectomy	Hypotension Hypovolemia Pulmonary embolus	Acute hypoxia/acidosis (check lactate)
Intravascular hemolysis Incompatible blood, malaria	Metastatic adenocarcinoma			
Tissue injury Obstetric complications, trauma, burns, crush injuries	Aortic aneurysm Giant hemangioma			
Malignancy Solid tumours, hematologic malignancies (especially APLM)				
Snake venom, fat embolism, heat stroke				

Clinical Features

- presence of both hemorrhage and clotting

Table 28. Clinical Features of DIC

Signs of Microvascular Thrombosis	Signs of Hemorrhagic Diathesis
Neurological: multifocal infarcts, delirium, coma, seizures Skin: focal ischemia, superficial gangrene Renal: oliguria, azotemia, cortical necrosis Pulmonary: ARDS GI: acute ulceration RBC: microangiopathic hemolysis	Bleeding from any site in the body (2° to decreased platelets and clotting factors) Neurologic: intracranial bleeding Skin: petechiae, ecchymosis, oozing from puncture sites Renal: hematuria Mucosal: gingival oozing, epistaxis, massive bleeding

Investigations

- primary hemostasis: decreased platelets
- secondary hemostasis: prolonged INR (PT), aPTT, TT, decreased fibrinogen and other factors
- fibrinolysis: increased FDPs or D-dimers, short euglobulin lysis time (i.e. accelerated fibrinolysis)
- extent of fibrin deposition: urine output, RBC fragmentation

Treatment

- recognize early and treat underlying disorder - supportive measures: hemodynamic and/or ventilator support, aggressive hydration, RBC transfusion if severe bleed
- in hemorrhage: replacement of hemostatic elements with platelet transfusion, frozen plasma, cryoprecipitate
 - British Hematology Guidelines:
 - maintain platelets $>50 \times 10^9/L$, hemoglobin $>80 \text{ g/L}$, calcium between 2.2-2.7 mmol/L, and avoid hypothermia
 - 4-5 units of FP if INR >1.5 or aPTT >38
 - 10 units of cryoprecipitate if fibrinogen $<1 \text{ g/L}$
 - 1 adult dose of buffy-coat platelets if $<10 \times 10^9/L$ (<20 if febrile, <50 before invasive procedure)
- in thrombotic phase: UFH or LMWH in critically ill, non-bleeding patients

Table 29. Screening Test Abnormalities in Coagulopathies

Increased INR Only	Increased PTT Only	Both Increased
Warfarin Vitamin K deficiency Factor VII deficiency Liver disease Factor VII inhibitors	Hemophilia A and B Heparin Antiphospholipid Ab Intrinsic factor inhibitors (e.g. FVIII) Factor XI and XII deficiency	Prothrombin deficiency Severe fibrinogen deficiency Factor V and X deficiency Severe liver disease Factor V and X, prothrombin, and fibrinogen inhibitors Excessive anticoagulation Severe vitamin K deficiency

Hypercoagulable Disorders

Hypercoagulability Workup – Venous Thrombosis

- workup for malignancy is suggested in the event of abnormal blood work, constitutional symptoms or physical exam suggestive of cancer
 - workup for hypercoagulable state is controversial and should only be done if it will alter treatment decisions
 - recommendations for a hypercoagulable workup include:
 - patients with recurrent or multiple thrombosis only if it will change management plans
 - warfarin-induced skin necrosis or neonatal purpura fulminans (protein C or S deficiency)
 - consider for patients with a family history of VTE who are considering OCP use
 - consider for patients who present with thrombosis at an unusual venous site only if it will change management plans
 - arterial thrombotic events have only been proven to be associated with APLA, HIT, JAK2 MPNs, and PNH

Important Etiologies of DIC

OMITS

- Obstetric complications
- Malignancy
- Infection
- Trauma
- Shock

Levels of fibrinogen can still be normal in DIC as it is an acute phase reactant
Serial fibrinogen levels should be measured to see if there is a trending decrease along with an increase in D-dimer

Differential Diagnosis of Elevated D-Dimer

- Arterial thromboembolic disease (MI, CVA, acute limb ischemia, AFib, intracardiac thrombus)
- Venous thromboembolic disease (DVT, PE)
- DIC
- Preeclampsia and eclampsia
- Abnormal fibrinolysis; use of thrombolytic agents
- Cardiovascular disease, CHF
- Severe infection/sepsis/inflammation
- Surgery/trauma (tissue ischemia, necrosis)
- Systemic inflammatory response syndrome
- Vasooocclusive episode of sickle cell disease
- Severe liver disease
- Malignancy
- Renal disease (nephrotic syndrome, acute/chronic renal failure)
- Normal pregnancy
- Venous malformation

American Society of Hematology Choosing Wisely Recommendations

- Do not test for thrombophilia in adult patients with venous thromboembolism occurring in the setting of major transient risk factors (surgery, trauma, or prolonged immobility)
- Do not use inferior vena cava filters routinely in patients with acute venous thromboembolism

- workup
 - initial
 - ♦ CBC, blood smear, coagulation studies, liver/renal function, urinalysis, hemolysis markers (if anemic)
 - ♦ malignancy history, age appropriate cancer screening
 - ♦ serology: antiphospholipid antibodies (APLA)
 - post-treatment (or ≥ 6 wk, as protein levels depleted/consumed by clot)
 - ♦ antithrombin (not on heparin)
 - ♦ proteins C, S (not on warfarin)
- note: most of these tests do not change management, and a negative test does not rule out a hypercoagulable state
 - thus, more focus on the reversible/treatable causes (APLA, cancer, etc.)

SELECTED CAUSES OF HYPERCOAGULABILITY LEADING TO VENOUS THROMBOEMBOLISM

Activated Protein C Resistance (Factor V Leiden)

- most common cause of hereditary thrombophilia
- 3-7% of European Caucasian population are heterozygotes
- point mutation in the Factor V gene (R506Q) results in resistance to inactivation of Factor Va by activated protein C

Prothrombin Gene Mutation (PT) G20210A

- 1-3% of European Caucasian population are heterozygotes
- G to A transposition at nucleotide position 20210 of the prothrombin gene promoter region results in increased levels of prothrombin, thus increased thrombin generation

Protein C and Protein S Deficiency

- protein C inactivates Factor Va and VIIIa using protein S as a cofactor
- protein C deficiency
 - homozygous or compound heterozygous: neonatal purpura fulminans
 - heterozygous
 - ♦ type I: decreased protein C levels
 - ♦ type II: decreased protein C activity
 - acquired: liver disease, sepsis, DIC, warfarin, certain chemotherapeutic agents
 - 1/3 of patients with warfarin necrosis have underlying protein C deficiency
- protein S deficiency
 - type I: decreased free and total protein S levels
 - type II: decreased protein S activity
 - type III: decreased free protein S levels
 - acquired: liver disease, DIC, pregnancy, nephrotic syndrome, inflammatory conditions, warfarin

Antithrombin Deficiency

- antithrombin slowly inactivates thrombin in the absence of heparin, rapidly inactivates thrombin in the presence of heparin
- autosomal dominant inheritance, urinary losses in nephrotic syndrome, or reduced synthesis in liver disease
- diagnosis must be made outside window of acute thrombosis and anticoagulation treatment (acute thrombosis, heparin, systemic disease all decrease antithrombin levels)
- deficiency may result in resistance to unfractionated heparin (LMWH may be considered, with monitoring of anti-Xa levels)
 - heparin resistance: suspect if $>35,000$ units of UFH required during 24 h use

Elevated Factor VIII Levels

- an independent marker of increased incident and recurrent thrombotic risk, but levels can also be increased in numerous states as an acute phase reactant, therefore its clinical use is controversial

Congenital Dysfibrinogenemia

- may predispose to thromboembolic disease, bleeding or both

Disorders of Fibrinolysis

- includes congenital plasminogen deficiency, tissue plasminogen activator deficiency, although association with VTE risk is not clear

Antiphospholipid Antibody Syndrome (APS)

- definition: ≥ 1 clinical and ≥ 1 laboratory criteria
 - clinical: thrombosis, recurrent (>3) early pregnancy losses <10 wk, one late fetal loss ≥ 10 wk (morphologically normal), or premature birth before 34 wk due to (pre)eclampsia or placental insufficiency
 - laboratory (must be confirmed on two occasions, tested ≥ 12 wk apart): anticardiolipin antibodies, anti- β_2 glycoprotein-I antibody, lupus anticoagulant
- mechanism: not well understood, antibodies interact with platelet membrane phospholipid causing increased activation; can also interfere with thrombin regulation, fibrinolysis, and inhibit the protein C pathway
- see [Rheumatology, RH12](#)

Common Causes of Hypercoagulability

CALM APES

- Protein C deficiency
- Antiphospholipid Ab
- Factor V Leiden
- Malignancy
- Antithrombin deficiency
- Prothrombin G20210A
- Increased Factor VIII (Eight)
- Protein S deficiency

Causes of Both Venous and Arterial Thrombosis include:

- Antiphospholipid antibodies
- Myeloproliferative neoplasms
- Heparin-induced thrombocytopenia
- Distal venous clot with patent foramen ovale
- Paroxysmal nocturnal hemoglobinuria

Protein C, protein S, and ATIII are decreased during acute thrombosis – therefore to test for deficiency, must be tested outside of this time period

Malignancy is a common cause of acquired hypercoagulability

Workup should include:

- Complete history and physical
- Routine blood work
- Urinalysis
- CXR
- Age appropriate screening: mammogram, Pap, PSA, colonoscopy
- Close follow-up
- No benefit with CT imaging

Although lupus anticoagulant prolongs PTT, this is a misnomer, as its main clinical feature is thrombosis

Venous Thromboembolism

Definition

- thrombus formation and subsequent inflammatory response in a superficial or deep vein
- superficial thrombophlebitis, deep vein thrombosis (DVT), and pulmonary embolism (PE)
- thrombi propagate in the direction of blood flow (commonly originating in calf veins)
- more common in lower extremity than upper extremity
- incidence ~1% if age >60 yr
- most important sequelae are pulmonary embolism (~50% chance with proximal DVT) and chronic venous insufficiency

Etiology (Virchow's Triad)

- endothelial damage
 - exposes endothelium to prompt hemostasis
 - leads to decreased inhibition of coagulation and local fibrinolysis
- venous stasis
 - immobilization (post-MI, CHF, stroke, post-operative) inhibits clearance and dilution of coagulation factors
- hypercoagulability
 - inherited (see *Hypercoagulable Disorders, H33*)
 - acquired
 - ♦ age (risk increases with age)
 - ♦ surgery (especially orthopedic, thoracic, GI, and GU)
 - ♦ trauma (especially fractures of spine, pelvis, femur or tibia, spinal cord injury)
 - ♦ neoplasms (especially lung, pancreas, colon, rectum, kidney, and prostate)
 - ♦ blood dyscrasias (myeloproliferative neoplasms, especially PV, ET), PNH, hyperviscosity (multiple myeloma, polycythemia, leukemia, sickle cell disease)
 - ♦ prolonged immobilization (CHF, stroke, MI, leg injury)
 - ♦ hormone related (pregnancy, OCP, HRT, SERMs)
 - ♦ APS
 - ♦ heart failure (risk of DVT greatest with right heart failure and peripheral edema)
- idiopathic (10-20% are later found to have cancer)

Clinical Features of DVT

- absence of physical findings does not rule out disease
- unilateral leg edema, erythema, warmth, and tenderness; purple-blue colour
- palpable cord (thrombosed vein)
- phlegmasia alba dolens (white appearance) and phlegmasia cerula dolens (acute pain and edema) with massive thrombosis
- Homan's sign (pain with foot dorsiflexion) is unreliable

Differential Diagnosis of DVT

- muscle strain or tear, lymphangitis or lymph obstruction, venous valvular insufficiency, ruptured popliteal cysts, cellulitis, arterial occlusive disease

Investigations for DVT

- D-dimer test only useful to rule out DVT if negative with low clinical suspicion of disease and no other acute medical issues
- doppler ultrasound is most useful diagnostic test for DVT
 - sensitivity and specificity for proximal DVT ~95%
 - sensitivity for calf DVT ~70%
- other non-invasive tests include MRI and impedance plethysmography
- venography is the gold standard, but is expensive, invasive, and higher risk
- CTPA or V/Q scan if PE suspected

Post-Thrombotic Syndrome

- development of chronic venous stasis signs and symptoms secondary to a deep venous thrombosis
- symptoms: pain, venous dilatation, edema, pigmentation, skin changes, venous ulcers
- clinical severity can be estimated based on the Villalta score
- large impact on quality of life following a DVT
- treatment: extremity elevation, exercise, continuous compression stockings, intermittent pneumatic compression therapy, skin/ulcer care
- for clinical features and treatment of PE, see *Respirology, R18*

Risk of VTE in Hospitalized Patients Receiving Ineffective Antithrombotic Therapy

Risk Factor	RR (95% CI)	P-value
Age >75 yr	1.79 (1.18-2.71)	0.007
Cancer	1.58 (1.01-2.51)	
Previous VTE	1.67 (1.01-2.77)	0.08
Obesity	0.94 (0.59-1.51)	0.91
Hormone therapy	0.51 (0.08-3.38)	0.70
Heart failure	.08 (0.72-1.62)	0.82
NYHA III	0.89 (0.55-1.43)	0.72
NYHA IV	1.48 (0.84-2.6)	0.27
Acute infectious disease	1.50 (1.00-2.26)	0.06
Acute rheumatic disease	1.45 (0.84-2.50)	0.27

Source: *JAMA* 2004;194:963-968

Virchow's Triad

- Endothelial damage
- Stasis
- Hypercoagulability

Wells' Score for DVT

Criteria (Score)

- Paralysis, paresis, or recent orthopedic casting of lower extremity (1)
- Recently bedridden (>3 d) or major surgery within past 4 wk (1)
- Localized tenderness in deep vein system (1)
- Swelling of entire leg (1)
- Calf swelling >3 cm than other leg (measured 10 cm below the tibial tuberosity) (1)
- Pitting edema greater in the symptomatic leg (1)
- Collateral non-varicose superficial veins (1)
- Active cancer or cancer treated within 6 mo (1)
- Alternative diagnosis more likely than DVT (e.g. Baker's cyst, cellulitis, muscle damage, superficial venous thrombosis) (-2)

Total Score Interpretation

- 3-8: High probability, 1-2: Moderate probability, -2-0: Low probability

Low-Molecular-Weight Heparin vs. Coumarin for the Prevention of Recurrent Venous Thromboembolism in Patients with Cancer

NEJM 2003;349:146-153

Study: RCT comparing the efficacy of LMWH (dalteparin) with an oral anti-coagulant agent (coumarin) in preventing recurrent thrombosis in patients with cancer.

Methods: Patients with cancer who had acute, symptomatic proximal DVT, PE, or both were randomly assigned to either dalteparin or coumarin treatment for 6 mo.

Results: 27 of 336 patients in the dalteparin group had recurrent VTE versus 53 of 336 patients in the coumarin group (hazard ratio, 0.48; $p=0.002$). The probability of recurrent thromboembolism at 6 mo was 9% and 17% in dalteparin and coumarin groups respectively. There was no significant difference in bleeding rates. The mortality rate was 39% in the dalteparin group and 41% in the coumarin group.

Conclusions: In patients with cancer and acute VTE, dalteparin was more effective than coumarin in decreasing the risk of recurrent thromboembolism without increasing the risk of bleeding.

Approach to Treatment of Venous Thromboembolism

Purpose

- prevent further clot extension (3 mo duration is optimal)
- prevent acute pulmonary embolism (occurs in up to 50% of untreated patients)
- reduce the risk of recurrent thrombosis (duration depends on presence of other risk factors)
- treatment of massive iliofemoral thrombosis with acute lower limb ischemia and/or venous gangrene (phlegmasia cerulea dolens)
- limit development of late complications (e.g. postphlebitic syndrome, chronic venous insufficiency, and chronic thromboembolic pulmonary HTN)

Initial Treatment

- low molecular weight heparin (LMWH)
 - administered SC, at least as effective as UFH with a lower bleeding risk
 - advantages: predictable dose response and fixed dosing schedule; lab monitoring not required; <1% HIT; safe and effective outpatient therapy
 - disadvantages: only partially reversible by protamine, long-term use associated with osteoporosis costly!
 - renally cleared – must adjust dose in patients with renal dysfunction
- unfractionated heparin (UFH)
 - in patient with average risk of bleed; use hospital-based nomograms that use bleeding risk and patient weight to determine appropriate dose
 - advantages: rapidly reversible by protamine
 - disadvantages: must monitor aPTT or heparin levels with adjustment of dose to reach therapeutic level (~2x normal value); monitor platelet counts for development of HIT
- alternatives to LMWH and UFH
 - direct thrombin inhibitors (hirudin, lepirudin, argatroban), direct factor Xa inhibitors (apixaban, rivaroxaban)
 - thrombolytic drugs (e.g. streptokinase, tPA) reserved for acute limb/life-threatening thrombosis, and low bleeding risk

Long-Term Treatment

- anticoagulation therapy
 - warfarin
 - standard treatment; should be initiated with heparin overlap: dual therapy for at least 48 hours with INR >2, due to initial prothrombotic state secondary to warfarin's inhibition of natural anticoagulants protein C/S, half-life of vitamin K factors and risk of warfarin-induced skin necrosis
 - INR: warfarin dosed to maintain INR at 2-3, monitor twice weekly for 1-2 wk. Discontinue heparin after INR >2.0 for 2 consecutive days
 - direct oral anticoagulants (DOACs)
 - ♦ apixaban or rivaroxaban; with no laboratory monitoring required, patients with CrCl > 50 ml/min
 - ♦ dabigatran (factor IIa inhibitor): LMWH or IV heparin for at least 5-10 days before initiating dabigatran, patients with CrCl >30 mL/min
 - ♦ important drug interactions to consider for DOACs (no relevant food interactions however)
 - cancer patients: LMWH more effective than warfarin at preventing recurrence of venous thrombosis in cancer patients
 - duration of anticoagulant treatment
 - provoked VTE with transient risk factor: 3 mo
 - provoked VTE with ongoing risk factor: consider indefinite therapy with annual reassessment
 - first unprovoked VTE: at least 3 mo, subsequent reassessment
 - unprovoked proximal DVT or PE: consider indefinite therapy with annual reassessment
 - second unprovoked VTE: consider indefinite therapy
 - cancer-associated DVT: at least 3 mo, longer if continued evidence of cancer
 - IVC filters
 - temporary filter indicated only if acute DVT (<4 wk) with significant contraindications to anticoagulant therapy (i.e. active bleeding) or if require interruption of anticoagulation (i.e. for urgent surgery)
 - must be retrieved once safe to do so as filter is pro-thrombotic in the long-term (consider anticoagulation if not retrieved)
 - special considerations
 - pregnancy: treat with LMWH during pregnancy, then LMWH or warfarin for 6 wk post-partum (minimum total anticoagulation time of 3-6 mo, but must include 6 wks post-partum, as this is a high risk period); avoid warfarin in pregnancy due to teratogenicity
 - surgery: avoid elective surgery in the first three months after a venous thromboembolic event
 - ♦ pre-operatively: IV heparin may be used up to 4-6 h pre-operatively
 - ♦ perioperatively: warfarin or DOACs discontinued for at least 3-5 d pre-operatively (consider mechanism of drug clearance)
 - surgery safe when INR <1.5 off of warfarin, normal PTT on dabigatran, drug-specific Xa level at zero for apixaban/ rivaroxaban/LMWH, normal PTT on IV unfractionated heparin

Duration of Treatment with Vitamin K Antagonists in Symptomatic Venous Thromboembolism

Cochrane DB Syst Rev 2009;CD0011367

Study: Meta-analysis of 8 RCTs (2,994 patients) comparing different durations of treatment with vitamin K antagonists in patients with symptomatic VTE.

Results: In patients treated with vitamin K antagonists for a prolonged period, the reduction in risk of recurrent VTE remained consistent regardless of the period of time since the index event (OR 0.18; 95% CI 0.13-0.26). In addition, there was no observed excess of VTE recurrences following cessation of prolonged treatment (i.e. rebound phenomenon) (OR 1.24; 95% CI 0.91-1.69). However, patients who received prolonged treatment had a persistent increase in their risk of major bleeding complications (OR 2.61; 95% CI 1.48-4.61).

Conclusion: Prolonged treatment with vitamin K antagonists leads to a consistent reduction in the risk of recurrent VTE for as long as therapy is continued. Therapy should be discontinued when the risk of harm from major bleeding (which remains constant over time) is of greater concern than the absolute risk of recurrent VTE (which declines over time). No specific recommendation was made regarding optimal duration of treatment.

Common Medications that Interact with Warfarin

- Acetaminophen (interference with vitamin K metabolism)
- Allopurinol
- NSAIDs (GI injury)
- Fluconazole
- Metronidazole
- Sulfamethoxazole
- Tamoxifen

Initiation of Warfarin Therapy Requires Bridging with Heparin Therapy for 4-5 Days

- 10 mg loading dose (for example) of warfarin causes a precipitous decline in protein C levels in first 36 h resulting in a transient hypercoagulable state
- Warfarin decreases Factor VII levels in first 48 h, INR is prolonged (most sensitive to Factor VII levels), however full antithrombotic effect is not achieved until Factor IX, X, and II are sufficiently reduced (occurs after ~4 d)

Low Risk Surgical Patients

<40 yr, no risk factors for VTE, general anesthetic (GA) <30 min, minor elective, abdominal, or thoracic surgery

Moderate Risk Surgical Patients

>40 yr, >1 risk factor for VTE, GA >30 min

High Risk Surgical Patients

>40 yr, surgery for malignancy or lower extremity orthopedic surgery lasting >30 min, inhibitor deficiency, or other risk factor

High Risk Medical Patients

Heart failure, severe respiratory disease, ischemic stroke and lower limb paralysis, confined to bed and have >1 additional risk factor (e.g. active cancer, previous VTE, sepsis, acute neurologic disease, IBD)

- post-operatively: IV heparin, LMWH, DOAC can be used for anticoagulation (consult with surgeon prior to re-initiation)
- for patients at high risk for thromboembolism (VTE <12 wk, recurrent VTE, antiphospholipid antibody syndrome, atrial fibrillation with prior stroke, mechanical heart valve), IV heparin or LMWH (bridging) should be given before and after the procedure while the INR is below 2.0

Prophylaxis

- consider for those with a moderate to high risk of thrombosis without contraindications
- non-pharmacological measures include: early ambulation, elastic compression stockings (TEDs), intermittent pneumatic compression (IPC)
- UFH 5,000 IU SC bid, UFH 5,000 IU SC tid or LMWH as per hospital protocol (e.g. enoxaparin 40 mg SC daily, dalteparin 5000 U SC qid), DOACs for orthopedic surgery thromboprophylaxis

Contraindications and Adverse Reactions of Anticoagulant Therapy

- absolute: active bleeding, severe bleeding diathesis, or platelets <20-30 x 10⁹/L (<20,000/mm³), intracranial bleeding, neuro or ocular surgery within <10 d
- relative: mild-moderate neurologic diathesis or thrombocytopenia, brain metastases, recent major trauma, major abdominal surgery within past 2 d, GI/GU bleed within 14 d, endocarditis, severe HTN (sBP >200 or dBP >120), recent stroke

Table 30. Contraindications of Anticoagulant Therapy

Absolute Contraindications to Treatment	Relative Contraindications to Treatment
Active bleeding	Mild-moderate bleeding diathesis or thrombocytopenia
Severe bleeding diathesis or platelet count <20 x 10 ⁹ /L (<20,000/mm ³)	Brain metastases
Intracranial bleeding	Recent major trauma
Neurosurgery or ocular surgery within 10 d	Recent stroke
	Major abdominal surgery within past 2 d
	GI/GU bleeding within 1-4 d
	Endocarditis
	Severe hypertension (sBP >200 or dBP >120)

Treatment of Pulmonary Embolism

- see [Respirology, R18](#)

Hematologic Malignancies and Related Disorders

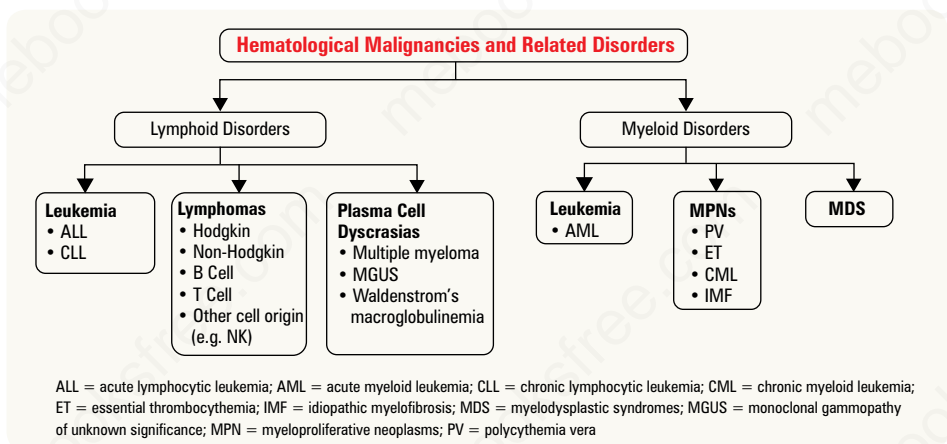

Figure 14. Overview of hematologic malignancies and related disorders

Myeloid Malignancies

Acute Myeloid Leukemia

Definition

- rapidly progressive malignancy characterized by failure of myeloid cells to differentiate beyond blast stage

Epidemiology

- incidence increases with age; median age of onset is 65 yr old; 80% of acute adult leukemias
- accounts for 10-15% of childhood leukemias

Typical Age of Presentation of Leukemias

- ALL: Children and older adults
- CML: 40-60 yr
- AML, CLL: >60 yr

Leukemia: malignant cells arise in bone marrow and may spread elsewhere (including blood, lymph nodes, and lymphoid tissue)
Lymphoma: malignant cells arise in lymph nodes and lymphoid tissues and may spread elsewhere (including blood and bone marrow) **BUT** the location where the malignant cells are found does not solely define the type of hematologic malignancy – classified based on the characteristics of the cell (histology, histochemistry, immunophenotyping, cytogenetics, molecular changes)

Acute Leukemia

Definition (WHO): presence of 20% blast cells or greater in bone marrow at presentation
Classification: divided into myeloid (AML) and lymphoid (ALL) depending on whether blasts are myeloblasts or lymphoblasts, respectively

2008 WHO classification of AML (2016 Revision)

- AML with recurrent genetic abnormalities
 - AML with t(8;21)(q22;q22.1);RUNX1-RUNX1T1
 - AML with inv(16)(p13.1q22) or t(16;16)(p13.1;q22);CBFB-MYH11
 - APL with PML-RARA
 - AML with t(9;11)(p21.3;q23.3);MLL3-KMT2A
 - AML with t(6;9)(p23;q34.1);DEK-NUP214
 - AML with inv(3)(q21.3q26.2) or t(3;3)(q21.3;q26.2);GATA2, MECOM
 - AML (megakaryoblastic) with t(1;22)(p13.3;q13.3);RBM15-MKL1
- Provisional entity: AML with BCR-ABL1
- AML with mutated NPM1
- AML with biallelic mutations of CEBPA
- Provisional entity: AML with mutated RUNX1
- AML with myelodysplasia-related changes
- Therapy-related myeloid neoplasms
- AML, NOS

Auer rods are pathognomonic for AML

Risk Factors

- myelodysplastic syndromes (MDS), benzene, radiation, Down Syndrome, alkylating agents as treatment for previous malignancy

Pathophysiology

- etiology subdivided into:
 - primary: *de novo*
 - secondary: hematologic malignancies (e.g. myeloproliferative disorders and MDS) or previous chemotherapeutic agents (e.g. alkylating agents)
- uncontrolled growth of blasts in marrow leads to:
 - suppression of normal hematopoietic cells
 - appearance of blasts in peripheral blood – risk of leukostasis
 - accumulation of blasts in other sites (e.g. skin, gums)
 - metabolic consequences; tumour lysis syndrome

Clinical Features

- anemia, thrombocytopenia (associated with DIC in promyelocytic leukemia), neutropenia (even with normal WBC), leads to infections, fever
 - accumulation of blast cells in marrow
 - skeletal pain, bony tenderness (especially sternum)
 - organ infiltration
 - gingival hypertrophy (particularly myelomonocytic leukemia) – may present to dentist first
 - hepatosplenomegaly (in ALL)
 - lymphadenopathy (not marked in ALL)
 - gonads (in ALL)
 - skin: leukemia cutis or myeloid sarcoma
 - eyes: hemorrhages and/or whitish plaques, Roth spots, cotton wool spots, vision changes (uncommon)
 - leukostasis/hyperleukocytosis syndrome (medical emergency)
 - large numbers of blasts interfere with circulation and lead to hypoxia and hemorrhage – can cause diffuse pulmonary infiltrates, CNS bleeding, respiratory distress, altered mental status, priapism
 - associated with AML more than ALL
 - metabolic effects; aggravated by treatment (rare)
 - increased uric acid → nephropathy, gout
- release of phosphate → decreased Ca^{2+} , decreased Mg^{2+}
- release of procoagulants → DIC (higher risk in acute promyelocytic leukemia)
 - decreased or normal K^+ before treatment, increased K^+ after treatment (from lysed cells)

Investigations

- blood work
 - CBC: anemia, thrombocytopenia, variable WBC
 - INR, aPTT, fibrin degradation products (FDP), fibrinogen (in case of DIC)
 - increased LDH, increased uric acid, increased PO_4^{3-} (released by leukemic blasts), decreased Ca^{2+} , decreased K^+
 - baseline renal and liver function tests
- peripheral blood film – circulating blasts with Auer rods (azurophilic granules) are pathognomonic for AML
- bone marrow aspirate for definitive diagnosis
 - blast count: AML >20% (normal is <5%)
 - morphologic, cytochemical, and/or immunophenotypic features are used to establish lineage and maturation (see sidebar for *WHO classification of AML, H37*)
- CXR to rule out pneumonia, ECG, MUGA scan prior to chemotherapy (cardiotoxic)

Treatment

- mainstay of treatment is chemotherapy (rapidly fatal without treatment)
- all AML subtypes are treated similarly, except acute promyelocytic leukemia (APL) with t(15:17) translocation
- all-trans-retinoic acid (ATRA) added to induce differentiation; arsenic trioxide + ATRA combination therapy for APL is non-inferior to traditional chemotherapy
- treatment strategy
 - Induction:** chemotherapy to induce complete remission of AML (see sidebar)
 - several possible regimens (e.g. cytarabine with anthracycline [daunorubicin])
 - patients with poor response to initial induction therapy – worse prognosis
 - must ensure reversal of DIC, platelet transfusions if <10
 - Consolidation:** to prevent recurrence
 - intensive consolidation chemotherapy
 - stem cell transplantation – autologous or allogeneic (younger patients with better performance status)
- consider acceleration with hematopoietic growth factors (e.g. G-CSF) if severe infection develops

Cure: survival that parallels age-matched population

Complete Remission: tumour load below threshold of detectable disease (normal peripheral blood film, normal bone marrow with <5% blasts, normal clinical state)

- supportive care
 - screening for infection via regular C&S of urine, stool, sputum, oropharynx, catheter sites, perianal area
 - fever: C&S of all orifices, CXR, start antibiotics
 - platelet and RBC transfusions (irradiated to prevent transfusion-related GVHD) ± EPO
 - prevention and treatment of metabolic abnormalities
 - ♦ allopurinol, rasburicase for prevention of hyperuricemia

Prognosis

- achievement of first remission
 - 70-80% if ≤60 yr old, 50% if >60 yr old
 - median survival 12-24 mo
 - prognosis is most related to 1) cytogenetics; classified as favourable, intermediate, or adverse and 2) molecular studies (i.e. NPM1+/FLT3- mutations)
 - prognosis depends on cytogenetics, age, performance status, prior cytotoxic agents or radiation therapy

Myelodysplastic Syndromes

Definition

- heterogeneous group of malignant stem cell disorders characterized by dysplastic and ineffective blood cell production resulting in peripheral cytopenias, and a variable risk of transformation to acute leukemias
- syndromes defined according to World Health Organization (WHO) classifications (see sidebar)

Pathophysiology

- disordered maturation: ineffective hematopoiesis despite presence of adequate numbers of progenitor cells in bone marrow (usually hypercellular); formed elements sometimes exhibit qualitative functional defects
- intramedullary apoptosis: programmed cell death within bone marrow
 - both processes lead to reduced mature cells in periphery
- <30% develop AML

Risk Factors

- elderly, post-chemotherapy, exposures (benzene, tobacco, radiation), inherited genetic abnormalities
- occurs in 4/100,000 patients >60 yr old

Clinical Features

- insidious onset: associated with pancytopenia; most patients asymptomatic at diagnosis
- infections and bleeding out of proportion with peripheral blood counts

Investigations

- diagnosed by:
 - anemia ± thrombocytopenia ± neutropenia
 - CBC and peripheral blood film
 - RBC: usually macrocytic with oval shaped red cells (macro-ovalocytes), decreased reticulocyte count
 - WBC: decreased granulocytes and abnormal morphology (e.g. bi-lobed or unsegmented nuclei = Pelger abnormality)
 - platelets: thrombocytopenia, abnormalities of size and cytoplasm (e.g. giant hypogranular platelets)
- bone marrow aspirate and biopsy with cytogenetic analysis required for definitive diagnosis
 - bone marrow: dysplastic and often normocellular/hypercellular
 - cytogenetics: high risk include partial or total loss of chromosomes 5, 7, and complex (>3 abnormalities)

Treatment

- low risk of transformation to acute leukemia (IPSS-R Very Low or Low)
 - erythropoietin stimulating agents weekly is first line in reducing transfusion requirements (EPO level must be <500)
 - If 5q deletion based on cytogenetics: lenalidomide PO
 - supportive care: RBC and platelet transfusion (consider iron chelation if frequent RBC transfusions)
- high risk of transformation to acute leukemia (IPSS-R Intermediate, High or Very High)
 - supportive care
 - stem cell transplantation if age <65 yr
 - epigenetic therapy: DNA methyltransferase inhibitors (e.g. 5-azacytidine), histone deacetylase inhibitors

Prognosis

- Revised International Prognostic Scoring System (IPSS-R) uses 5 factors to estimate mean survival:
 - cytology, % bone marrow blasts, hemoglobin, platelets, absolute neutrophil count
 - based on the calculated score, a patient's MDS prognostic risk is "Very Low", "Low", "Intermediate", "High", or "Very High" with a mean survival of 8.7, 5.3, 3.0, 1.6, and 0.8 yr, respectively

2008 WHO MDS Classification (2016 Revision)

- MDS with single lineage dysplasia
- MDS with ring sideroblasts (MDS-RS)
 - MDS-RS and single lineage dysplasia
 - MDS-RS and multilineage dysplasia
- MDS with multilineage dysplasia
- MDS with excess blasts
- MDS with isolated del(5q)
- MDS, unclassifiable
- Provisional entry: Refractory cytopenia of childhood

MDS is a cause of macrocytic anemia

Use of Epoetin and Darbepoetin in Patients with Cancer

Blood 2008;111:25-41

Clinical practice guideline update by American Societies of Hematology and Clinical Oncology (2007).

Initial Recommendations

1. Initiate an erythropoiesis-stimulating agent (ESA) when hemoglobin (Hb) is 100 g/L (10 g/dL) in patients with palliative chemotherapy-associated anemia to decrease the need for transfusions.
2. Discontinue ESAs when patient not responding to treatment beyond 6-8 wk.
3. Monitor iron stores and supplement iron intake for ESA-treated patients when necessary.
4. Use ESAs cautiously with chemotherapy or in patients with an elevated risk for thromboembolic complications.
5. It is not recommended that ESA be used for therapy in patients with cancer who are not receiving chemotherapy, as it increases thromboembolic risks and lowers survival rate. Patients with low-risk myelodysplasia are an exception.

Myeloproliferative Neoplasms

Definition

- clonal myeloid stem cell abnormalities leading to overproduction of one or more cell lines (leading to abnormalities in erythrocytes, platelets, and other cells of myeloid lineage)

Epidemiology

- mainly middle-aged and older patients (peak 60-80 yr)

Prognosis

- may develop marrow fibrosis with time
- all disorders may progress to AML

Table 31. Chronic Myeloproliferative Disorders

	CML	PV	IMF	ET
Hct	↓/N	↑↑	↓	N
WBC	↑↑	↑	↑/↓	N
Plt	↑/↓	↑	↑/↓	↑↑↑
Marrow Fibrosis	±	±	+++	±
Splenomegaly	+++	+	+++	+
Hepatomegaly	+	+	++	-
Genetic Association	<i>bcr-abl</i> mut. (95+%)	JAK2 mut. (96%)	JAK2 mut. (~50%) CALR mut (~30%)	JAK2 mut. (~50%) CALR mut (~30%)

CML = chronic myeloid leukemia; ET = essential thrombocythemia; IMF = idiopathic myelofibrosis; PV = polycythemia vera CALR = Calreticulin

Myelodysplastic Syndromes
ineffective maturation
Myeloproliferative Neoplasms
overproduction of mature cells

Chronic Myeloid Leukemia

Definition

- myeloproliferative disorder characterized by increased proliferation of the granulocytic cell line without the loss of their capacity to differentiate

Epidemiology

- occurs in any age group (mostly middle age to elderly) with a median age of 65 yr

Pathophysiology

- Philadelphia chromosome (Ph)
 - translocation between chromosomes 9 and 22
 - the *c-Abl* proto-oncogene is translocated from chromosome 9 to “breakpoint cluster region” (BCR) of chromosome 22 to produce BCR-Abl fusion gene, an active tyrosine kinase

Clinical Features

- 3 clinical phases
 - chronic phase: 85% diagnosed here
 - few blasts (<10%) in peripheral film
 - ± slightly elevated eosinophils and basophils
 - no significant symptoms
 - accelerated phase: impaired neutrophil differentiation
 - circulating blasts (10-19%) with increasing peripheral basophils (pruritus)
 - CBC: thrombocytopenia $<100 \times 10^9/L$
 - cytogenetic evidence of clonal evolution
 - worsening constitutional symptoms and splenomegaly (extramedullary hematopoiesis)
 - blast crisis: more aggressive course, blasts fail to differentiate
 - blasts (>20%) in peripheral blood or bone marrow; reflective of acute leukemia (1/3 ALL, 2/3 AML)
- clinical presentation
 - 20-50% of patients are asymptomatic when diagnosed (incidental lab finding)
 - nonspecific symptoms
 - fatigue, weight loss, malaise, excessive sweating, fever
 - secondary to splenic involvement
 - early satiety, LUQ pain/fullness, shoulder tip pain (referred)
 - splenomegaly (most common physical finding)
 - anemia
 - bleeding: secondary to platelet dysfunction
 - pruritus, PUD: secondary to increased blood histamine
 - leukostasis, priapism, encephalopathy (rare): secondary to very elevated WBC (rare)

Basophilia is uncommon in other medical conditions

Investigations

- elevated WBC, decreased/normal RBC, increased/decreased platelets, increased basophils
 - WBC differential shows a bimodal distribution, with predominance of myelocytes and neutrophils

- peripheral blood film
 - leukoerythroblastic picture (immature red cells and granulocytes present, e.g. myelocytes and normoblasts)
 - presence of different mid-stage progenitor cells differentiates it from AML
- bone marrow
 - myeloid hyperplasia with left shift, increased megakaryocytes, mild fibrosis
- molecular and cytogenetic studies of bone marrow or peripheral blood for Philadelphia chromosome
- abdominal imaging for spleen size

Treatment

- **symptomatic**
 - allopurinol and antihistamines
- **chronic phase**
 - imatinib mesylate inhibits proliferation and induces apoptosis by inhibiting tyrosine kinase activity in cells positive for bcr-abl
 - ♦ if loss of response or intolerance (~40%), trial of 2nd generation TKIs: dasatinib, nilotinib, or bosutinib
 - ♦ dasatinib and nilotinib may also be considered for first line management
 - interferon- α : may improve response to tyrosine kinase inhibitors; typically now only used for pregnant patients
 - hydroxyurea in palliative setting to reduce WBC
- **accelerated phase or blast phase**
 - refer for clinical trial or 2nd/3rd generation TKI and prepare for allogeneic stem cell transplant patients, in blast phase typically get standard AML induction
- stem cell transplantation may be curative: to be considered in young patients who do not meet therapeutic milestones
- treatment success is monitored based on therapeutic milestones
 - hematologic: improved WBC and platelet counts, reduced basophils
 - cytogenetic: undetectable Philadelphia-chromosome in the bone marrow
 - molecular: reduction/absence of bcr-abl transcripts in periphery and marrow

Prognosis

- survival dependent on response
 - those achieving complete cytogenetic response (CCR) on imatinib by 18 mo of therapy: 6 yr overall survival >90%
 - those who do NOT achieve CCR on imatinib: 6 yr overall survival of 66%
- acute phase (blast crisis – usually within 3-5 yr)
 - 2/3 develop a picture similar to AML
 - ♦ unresponsive to remission induction
 - 1/3 develop a picture similar to ALL
 - ♦ remission induction (return to chronic phase) achievable

Chronic Myeloproliferative Neoplasias: Six Year Follow-Up of Patients Receiving Imatinib for the First-Line Treatment of CML

Leukemia 2009;23:1054-1061

Study: The Randomized Study of Interferon vs. STI571 (IRIS) trial enrolled patients with chronic phase chronic myeloid leukemia (CML-CP) to either imatinib (n=533) or interferon- α (IFN) plus cytarabine (n=553).

Results: Assessing the imatinib arm specifically at the sixth year point, there were no reports of disease progression to accelerated phase (AP) or blast crisis (BC), toxicity profile was unchanged, and cytogenetic response rate was 82%. Estimated event-free survival was 83% and rate of freedom from progression to AP and BC was 93%.

Conclusion: This 6-year update of IRIS demonstrates the efficacy and safety of imatinib as first-line therapy for CML patients.

Detection of the *bcr-abl* fusion gene is a diagnostic test for CML (present in over 90% of patients)

Polycythemia Vera

Definition

- stem cell disorder characterized by elevated RBC mass (erythrocytosis) \pm increased white cell and platelet production
- diagnosis (WHO 2016) requires meeting either all 3 major criteria, or the first 2 major criteria and the minor criterion
 - Major Criteria
 1. hemoglobin >165 g/L in men, >160 g/L in women, OR Hct >49% in men or >48% in women, OR increased red cell mass (>25% above mean normal predicted value)
 2. bone marrow biopsy showing hypercellularity for age with trilineage growth (panmyelosis) with prominent erythroid, granulocytic, and megakaryocytic proliferation
 3. presence of JAK2 V617F or JAK2 exon 12 mutation
 - Minor Criteria
 1. serum erythropoietin level below reference range for normal (must have at least two major criteria if using erythropoietin level)

Clinical Features

- symptoms are secondary to high red cell mass and hyperviscosity (see Erythrocytosis, H6)
- thrombotic complications: DVT, PE, Budd-Chiari (hepatic vein thrombosis), portal vein thrombosis, thrombophlebitis, increased incidence of stroke, MI
 - due to increased blood viscosity, increased platelet number and/or activity
 - bleeding complications: epistaxis, gingival bleeding, ecchymoses, and GI bleeding
 - if high platelet counts with associated acquired vWD
- erythromelalgia (burning pain in hands and feet and erythema of the skin)
 - associated with platelets >400 $\times 10^9/L$
 - pathognomonic microvascular thrombotic complication in PV and ET
- pruritus, especially after warm bath or shower (40%) due to cutaneous mast cell degranulation and histamine release
- epigastric distress, PUD
 - due to increased histamine from tissue basophils, alterations in gastric mucosal blood flow due to increased blood viscosity

Erythromelalgia is a pathognomonic microvascular thrombotic complication in PV and ET

Cardiovascular Events and Intensity of Treatment in Polycythemia Vera

NEJM 2013;368:22-33

Study: Prospective, RCT, mean follow-up of 28.9 mo. Blinding not described.

Population: 365 patients with JAK2-positive polycythemia vera being treated with phlebotomy, hydroxyurea, or both.

Intervention: Patients were randomized to a target hematocrit <45% (low-hematocrit group) or 45-50% (high-hematocrit group).

Outcome: Composite of time until death from cardiovascular causes of major thrombotic events.

Results: The hazard ratio (HR) for the primary outcome was 3.91 (95% CI 1.45-10.53, $p=0.007$), while the HR for the primary outcome plus superficial venous thrombosis was 2.69 (95% CI 1.19-6.12, $p=0.02$) for the high-hematocrit vs. low-hematocrit group.

Conclusions: The hematocrit target of <45% was associated with a lower incidence of CV death, major thrombotic events, and superficial venous thrombosis in patients with polycythemia vera.

- gout (hyperuricemia)
 - due to increased cell turnover
- characteristic physical findings
 - plethora (ruddy complexion) of face (70%), palms
 - splenomegaly (70%), hepatomegaly (40%)

Investigations

- see *Erythrocytosis, H6*
- must rule out secondary polycythemia if high Epo level

Treatment

- phlebotomy to keep hematocrit <45%
- hydroxyurea (prior thrombosis or symptoms, severe coronary artery disease, refractory to phlebotomy)
- low-dose Aspirin® (for antithrombotic prophylaxis, will also treat erythromelalgia)
- allopurinol: as needed
- antihistamines: as needed

Prognosis

- 10-20 yr survival with treatment
- complicated by thrombosis, hemorrhage, leukemic transformation (AML)

Efficacy and Safety of Low-dose Aspirin® in Polycythemia Vera

NEJM 2004;350:114-124

Study: Double-blind, placebo-controlled, RCT.

Participants: 518 patients with polycythemia vera (PV) with no clear indication for, or contraindication to, ASA therapy.

Intervention: Patients received either low-dose ASA 100 mg daily (n=253) or placebo (n=265) and were followed for up to 5 yr.

Primary Outcome: Cumulative rate of (I) nonfatal MI, nonfatal stroke, or death from cardiovascular causes and the cumulative rate of (II) the previous 3 plus PE and major venous thrombosis.

Results: Primary outcomes (I) and (II) were reduced with treatment compared to placebo (RR 0.41; p=0.09 and RR 0.4; p=0.03, respectively). There were no differences in overall or cardiovascular mortality and major bleeding episodes.

Conclusion: Low-dose ASA can safely prevent thrombotic complications in patients with PV.

Myelofibrosis can be either primary (idiopathic) or occur as a transformation of an antecedent PV or ET

A "leukoerythroblastic" blood film (RBC and granulocyte precursors) implies bone marrow infiltration with malignancy (e.g. leukemias, solid tumour metastases) or fibrosis (e.g. IMF)

IMF typically has a dry BM aspirate and teardrop RBCs (aspiration gives no blood cells)

A Double-Blind, Placebo-Controlled Trial of Ruxolitinib for Myelofibrosis

NEJM 2012;366:799-807

Study: Double-blinded RCT of 309 patients with myelofibrosis randomized to ruxolitinib or placebo.

Outcome: Primary outcome was reduction in spleen volume of >35% at 24 wk. Secondary outcomes were durability of response, symptom burden, and overall survival.

Results: A greater proportion of patients on ruxolitinib had reduction in spleen volume >35% (41.9% vs. 0.7%) and this was sustained in 67% at 48 wk. Ruxolitinib also led to greater symptom improvement (45% vs. 5.3%) and less mortality (13 vs. 24). There was no difference in rate of discontinuation due to adverse events (11.0% vs. 10.6%) but anemia and thrombocytopenia were more common with ruxolitinib.

Conclusions: Ruxolitinib reduced spleen size, improved symptoms and improved survival, compared with placebo.

Idiopathic Myelofibrosis

Definition

- excessive bone marrow fibrosis leading to marrow failure
- characterized by anemia, extramedullary hematopoiesis, leukoerythroblastosis, teardrop red cells in peripheral blood and hepatosplenomegaly

Epidemiology

- rare, median age at presentation is 65 yr

Pathophysiology

- abnormal myeloid precursor postulated to produce dysplastic megakaryocytes that secrete fibroblast growth factors
 - stimulates fibroblasts and stroma to deposit collagen in marrow
- increasing fibrosis causes early release of hematopoietic precursors leading to:
 - leukoerythroblastic blood film (primitive RBCs and WBCs present in blood)
 - migration of precursors to other sites: extramedullary hematopoiesis (leading to hepatosplenomegaly)

Clinical Features

- anemia (severe fatigue is most common presenting complaint, pallor on exam in >60%)
- weight loss, fever, night sweats → secondary to hypermetabolic state
- splenomegaly (90%) → secondary to extramedullary hematopoiesis; may cause early satiety
- hepatomegaly (70%) → may get portal hypertension
- bone and joint pain → secondary to osteosclerosis, gout
- signs of extramedullary hematopoiesis (depends on organ involved)

Investigations

- CBC: anemia, variable platelets, variable WBC
- biochemistry: increased ALP (liver involvement, bone disease), increased LDH (2° to ineffective hematopoiesis), increased uric acid (increased cell turnover), increased B₁₂ (2° to increased neutrophil mass)
- blood film: leukoerythroblastosis with teardrop RBCs, nucleated RBCs, variable polychromasia, large platelets, and megakaryocyte fragments
- JAK2 PCR and calreticulin PCR
- bone marrow aspirate: "dry tap" in as many as 50% of patients (no blood cells aspirated)
- bone marrow biopsy (essential for diagnosis): fibrosis, atypical megakaryocytic hyperplasia, thickening and distortion of the bony trabeculae (osteosclerosis)

Treatment

- allogeneic stem cell transplant is potentially curative
- JAK2 inhibitors (Ruxolitinib)
- symptomatic treatment
 - transfusion for anemia
 - erythropoietin: 30-50% of patients respond
 - androgens for anemia (e.g. danazol has shown transient response with response rates of <30%)
 - hydroxyurea for splenomegaly, thrombocytosis, leukocytosis, systemic symptoms
 - ♦ interferon-α (as second line therapy)
 - ♦ splenectomy (as third line therapy; associated with high mortality and morbidity)
 - radiation therapy for symptomatic extramedullary hematopoiesis, symptomatic splenomegaly

Prognosis

- Dynamic International Prognostic Scoring System (DIPSS) Plus for IMF uses 5 risk factors along with karyotype, platelet count, and transfusion status to predict survival
 - presence of constitutional symptoms; age >65; hemoglobin <100 g/L; leukocyte count >25,000/mm³; circulating blast cells ≥1%
 - based on the calculated score, a patient's IMF is categorized as "low", "intermediate 1", "intermediate 2", or "high" with a mean survival of 185, 78, 35, and 16 mo, respectively
- risk of transformation to AML (8-10%)

Essential Thrombocythemia

Definition

- overproduction of platelets in the absence of recognizable stimulus
- must rule out secondary thrombocythemia

Epidemiology

- increases with age; F:M = 2:1, but F=M at older age

Diagnosis (2008 WHO Criteria) requires meeting all four criteria:

1. sustained platelet count >450 x 10⁹/L
2. bone marrow biopsy specimen showing proliferation mainly of the megakaryocytic lineage with increased number of enlarged, mature megakaryocytes; no significant increase or left shift of neutrophil granulopoiesis or erythropoiesis
3. not meeting WHO criteria for PV, primary myelofibrosis, bcr-abl CML, or myelodysplastic syndrome or other myeloid neoplasms
4. demonstration of JAK2 V617F or calreticulin (or in its absence another clonal marker), no evidence for reactive thrombocytosis

Clinical Features

- often asymptomatic
- vasomotor symptoms (40%)
 - headache (common), dizziness, syncope
 - erythromelalgia (burning pain of hands and feet, dusky colour, usually worse with heat, caused by platelet activation → microvascular thrombosis)
- thrombosis (arterial and venous)
- bleeding (often GI; associated with platelets >1,000 x 10⁹/L)
- constitutional symptoms, splenomegaly
- pregnancy complications; increased risk of spontaneous abortion
- risk of transformation to AML (0.6-5%), myelofibrosis

Investigations

- CBC: increased platelets; may have abnormal platelet aggregation studies or vWD studies
- JAK2 PCR assay; if negative, CALR PCR assay
- bone marrow hypercellularity, megakaryocytic hyperplasia, giant megakaryocytes
- increased K⁺, increased PO₄³⁻ (2° to release of platelet cytoplasmic contents)
- diagnosis: exclude other myeloproliferative disorders and reactive thrombocytosis

Treatment

- low dose ASA if previous history of thrombotic event, ≥1 cardiovascular risk factors, older, or symptomatic
- cytoreductive therapy if thrombosis or thrombotic symptoms: hydroxyurea (HU) (1st line therapy), anagrelide, interferon-α, or 32P (age >80 or lifespan <10 yr)

Etiology of Secondary Thrombocythemia

- Infection
- Inflammation (IBD, arthritis)
- Malignancy
- Hemorrhage
- Iron deficiency
- Hemolytic anemia
- Post splenectomy
- Post chemotherapy

Anagrelide vs. Hydroxyurea for Essential Thrombocythemia: ANAHYDRET Study, A Randomized Controlled Trial

Blood 2013;121:1720-8

Study: Prospective, non-inferiority, RCT. Majority of patients followed beyond 1 yr.

Population: 259 previously untreated, high-risk patients with essential thrombosis as per the WHO guidelines.

Intervention: Patients were randomized to receive either non-immediate release formulation of anagrelide or hydroxyurea.

Outcome: Examined platelet counts, hemoglobin levels, leukocyte counts, and occurrence of ET-related events.

Results: The hazard ratio (HR) of developing thrombocythemia was 1.19 (95% CI 0.61-2.30). The HR for a reduction of hemoglobin was 1.03 (95% CI 0.57-1.81), and 0.92 (95% CI 0.57-1.46) for leukocytosis. There was no statistical difference in occurrence of major or minor arterial or venous thrombosis, severe or minor bleeding events, or rate of discontinuation between the two arms.

Conclusions: In patients with ET, anagrelide is non-inferior to hydroxyurea in the prevention of thrombotic complications.

There is an asymptomatic "benign" form of essential thrombocythemia with a stable or slowly rising platelet count; treatment includes observation, ASA, sulfinpyrazone, or dipyridamole

Lymphoid Malignancies

Acute Lymphoblastic Leukemia

Definition

- malignant disease of the bone marrow in which early lymphoid precursors proliferate and replace the normal hematopoietic cells of the marrow
- WHO subdivides ALL into two types depending on cell of origin
 - 1. B-cell: precursor B lymphoblastic leukemia
 - 2. T-cell: precursor T lymphoblastic leukemia
- the French-American-British (FAB) classification (L1, L2, L3) is no longer encouraged, as morphology is not prognostic

75% of ALL occurs in children <6 yr old; second peak at age 40

Clinical Features

- see *Acute Myeloid Leukemia, H37* for full list of symptoms
- distinguish ALL from AML based on Table 32
- clinical symptoms usually secondary to:
 - bone marrow failure: anemia, neutropenia (50% present with fever; also infections of oropharynx, lungs, perianal region), thrombocytopenia
 - organ infiltration: tender bones, lymphadenopathy, hepatosplenomegaly, meningeal signs (headache, N/V, visual symptoms; especially in ALL relapse)

Investigations

- CBC: increased leukocytes $>10 \times 10^9/L$ (occurs in 50% of patients); neutropenia, anemia, or thrombocytopenia
- may have increased uric acid, K^+ , PO_4^{3-} , Ca^{2+} , LDH
- PT, aPTT, fibrinogen, D-dimers for DIC
- leukemic lymphoblasts lack specific morphological (no granules) or cytochemical features, therefore diagnosis depends on immunophenotyping
- cytogenetics: Philadelphia (Ph) chromosome in ~25% of adult ALL cases
- CXR: patients with ALL may have a mediastinal mass
- LP prior to systemic chemotherapy to assess for CNS involvement (ensure adequate platelet count and PT/aPTT)

Treatment

- eliminate abnormal clonal cells
 1. induction chemotherapy: to induce complete remission (undetectable leukemic blasts, restore normal hematopoiesis)
 2. consolidation and/or intensification of chemotherapy
 - ♦ consolidation: continuing same chemotherapy to eliminate subclinical leukemic cells
 - ♦ intensification: high doses of different (non-cross-reactive) chemotherapy drugs to eliminate cells with resistance to primary treatment
 3. maintenance chemotherapy: low dose intermittent chemotherapy over prolonged period (2-3 yr) to prevent relapse
 4. prophylaxis: CNS radiation therapy or methotrexate (intrathecal or systemic)
- hematopoietic stem cell transplantation: potentially curative (due to pre-implant myeloablative chemoradiation and post-implant graft-versus-leukemia effect) but relapse rates and non-relapse mortality high

Treatment of ALL vs. AML

- No proven benefit of maintenance chemotherapy in AML
- No routine CNS prophylaxis in AML

Prognosis

- depends on response to initial induction or if remission is achieved following relapse
- good prognostic factors: young, WBC $<30 \times 10^9/L$, T-cell phenotype, absence of Ph chromosome, early attainment of complete remission
- achievement of first remission: 60-90%
- childhood ALL: 75% long-term remission (>5 yr)
 - higher cure rates in children because of better chemotherapy tolerance, lower prevalence of BCR-Abl fusion gene (associated with chemotherapeutic resistance)
- adult ALL: 30-40% 5 yr survival

Table 32. Differentiating AML From ALL

AML	ALL
Big people (adults)	Small people (kids)
Big blasts	Small blasts
Big mortality rate	Small mortality rate (kids)
Lots of cytoplasm	Less cytoplasm
Lots of nucleoli (3-5)	Few nucleoli (1-3)
Lots of granules and Auer rods	No granules
Myeloperoxidase, Sudan black stain	PAS (periodic acid-Schiff)
Maturation defect beyond myeloblast or promyelocyte	Maturation defect beyond lymphoblast

To Differentiate AML From ALL:
Remember Big and SmALL

Lymphomas

Definition

- collection of lymphoid malignancies in which malignant lymphocytes accumulate at lymph nodes and lymphoid tissues
 - leading to lymphadenopathy, extranodal disease, and constitutional symptoms

Table 33. Ann Arbor System for Staging Lymphomas

Stage	Description
I	Involvement of a single lymph node region OR extralymphatic organ/site (Stage IE)
II	Involvement of two or more lymph node regions or an extralymphatic site and one or more lymph node regions on same side of diaphragm
III	Involvement of lymph node regions on both sides of the diaphragm; may or may not be accompanied by single extra lymphatic site or splenic involvement
IV	Diffuse involvement of one or more extralymphatic organs including bone marrow

- subtypes
 - A = absence of B-symptoms (*see Approach to Lymphadenopathy, H12*)
 - B = presence of B-symptoms

Table 34. Chromosome Translocations

Translocation	Gene Activation	Associated Neoplasm
t(2;5)	ALK1 mutation	Anaplastic large cell lymphoma
t(8;14)	c-myc activation	Burkitt's lymphoma
t(14;18)	bcl-2 activation	Follicular lymphoma
t(11;14)	Overexpression of cyclin D1 protein	Mantle cell lymphoma
t(11;18)	MALT1 activation	Mucosa-associated lymphoid tissue (MALT)

Hodgkin Lymphoma

Definition

- malignant proliferation of lymphoid cells with Reed-Sternberg cells (thought to arise from germinal centre B-cells)

Epidemiology

- bimodal distribution with peaks at 20 yr and >50 yr
- association with Epstein-Barr virus in up to 50% of cases, causal role not determined

Clinical Features

- asymptomatic lymphadenopathy (70%)
 - non-tender, rubbery consistency
 - cervical/supraclavicular (60-80%), axillary (10-20%), inguinal (6-12%)
- splenomegaly (50%) ± hepatomegaly
- mediastinal mass
 - found on routine CXR, may be symptomatic (cough)
 - rarely may present with SVC syndrome, pleural effusion
- systemic symptoms
 - B symptoms (especially in widespread disease; fever in 30%), pruritus
- non-specific/paraneoplastic
 - alcohol-induced pain in nodes, nephrotic syndrome
- starts at a single site in lymphatic system (node), spreads first to adjacent nodes
 - disease progresses in contiguity with lymphatic system

Investigations

- CBC
 - anemia (chronic disease, rarely hemolytic), eosinophilia, lymphopenia, platelets normal or increased early, decreased in advanced disease
- biochemistry
 - HIV serology
 - liver enzymes and/or LFTs (liver involvement)
 - renal function tests (prior to initiating chemotherapy)
 - ALP, Ca²⁺ (bone involvement)
 - ESR, LDH (monitor disease progression)
- imaging
 - CXR, CT chest (lymph nodes, mediastinal mass), CT abdomen/pelvis (liver or spleen involvement), PET scans have replaced gallium scans

American Society of Hematology Choosing Wisely Recommendation

Limit surveillance CT scans in asymptomatic patients after curative-intent treatment for aggressive lymphoma

- Ann Arbor staging can be used for both Hodgkin and non-Hodgkin lymphoma, but grade/histology is more important for non-Hodgkin lymphoma because the outcome differs significantly depending on type of lymphoma
- Prognostic scores are different for indolent versus aggressive lymphomas
- Highly aggressive lymphomas act like acute leukemias

Hodgkin is distinguished from non-Hodgkin lymphoma by the presence of Reed-Sternberg cells

Hodgkin lymphoma classically presents as a painless, non-tender, firm, rubbery enlargement of superficial lymph nodes, most often in the cervical region

- cardiac function assessment (MUGA scan or echocardiography): for patients at high risk of pre-treatment cardiac disease (age >60, history of HTN, CHF, PUD, CAD, MI, CVA, malnourished), treatment can be cardiotoxic
- PFTs: if history of lung disease (COPD, smoking, previous radiation to lung)
- excisional lymph node or core biopsy confirms diagnosis
- bone marrow biopsy to assess marrow infiltration (only necessary if B-symptoms, stage III or IV, bulky disease or cytopenia)

Treatment

- stage I-II: chemotherapy (ABVD) followed by involved field or involved site radiotherapy (XRT)
- stage III-IV: chemotherapy (ABVD) with XRT for bulky disease
- relapse, resistant to therapy: high dose chemotherapy, autologous stem cell transplant
 - PET scan results essential in clarifying disease response

Complications of Treatment

- cardiac disease: secondary to XRT, adriamycin is also cardiotoxic
- pulmonary disease: secondary to bleomycin (interstitial pneumonitis)
- infertility: recommend sperm banking
- secondary malignancy in irradiated field
 - <2% risk of MDS, AML (secondary to treatment, usually within 8 yr)
 - solid tumours of lung, breast; >8 yr after treatment
 - non-Hodgkin lymphoma
- hypothyroidism: post XRT

Prognosis

- Hasenclever adverse prognostic factors:
 1. serum albumin <40 g/L
 2. hemoglobin <105 g/L
 3. male
 4. stage IV disease
 5. age \geq 45 yr
 6. leukocytosis (WBC $>1.5 \times 10^9/L$)
 7. lymphocytopenia (lymphocytes $<0.06 \times 10^9/L$ or $<8\%$ of WBC count or both)
- prognostic score
 - each additional adverse prognostic factor decreases freedom from progression at 5 yr (FFP)

Treatment of HL depends on stage; treatment of NHL depends on histologic subtype

International Prognostic Factors Project 1998

Prognostic Factors	FFP
0	84%
1	77%
2	67%
3	60%
4	51%
5-7	42%

FFP = freedom from progression at 5 yr

Non-Hodgkin Lymphoma

Definition

- malignant proliferation of lymphoid cells of progenitor or mature B- or T-cells

Classification

- multiple classification systems exist at present and may be used at different centres
- can originate from both B- (85%) and T- or NK- (15%) cells
 - B-cell NHL: e.g. diffuse large B-cell lymphoma, follicular lymphoma, Burkitt's lymphoma, mantle cell lymphoma
 - T-cell NHL: e.g. mycosis fungoides (skin), TCL-NOS, anaplastic large cell lymphoma
- WHO/REAL classification system: 3 categories of NHLs based on natural history
 - indolent (35-40% of NHL): e.g. follicular lymphoma, small lymphocytic lymphoma/CLL, mantle cell lymphoma
 - aggressive (~50% of NHL): e.g. diffuse large B-cell lymphoma
 - highly aggressive (~5% of NHL): e.g. Burkitt's lymphoma

Clinical Features

- painless superficial lymphadenopathy, usually >1 lymph node region
- usually presents as widespread disease (exception is aggressive lymphoma)
- constitutional symptoms not as common as in Hodgkin lymphoma
- cytopenia: anemia \pm neutropenia \pm thrombocytopenia can occur when bone marrow is involved
- abdominal signs
 - hepatosplenomegaly
 - retroperitoneal and mesenteric involvement (second most common site of involvement)
- oropharyngeal involvement in 5-10% with sore throat and obstructive apnea
- extranodal involvement: most commonly GI tract; also testes, bone, kidney
- CNS involvement in 1% (often with HIV)

NHL: Associated Conditions

- Immunodeficiency (e.g. HIV)
- Autoimmune diseases (e.g. SLE)
- Infections (e.g. EBV)

Investigations

- CBC
 - normocytic normochromic anemia
 - autoimmune hemolytic anemia rare
 - advanced disease: thrombocytopenia, neutropenia, and leukoerythroblastic anemia
- peripheral blood film may show lymphoma cells

- flow cytometry of peripheral blood lymphocytosis is valuable for low-grade NHL
- biochemistry
 - increase in uric acid
 - abnormal LFTs in liver metastases
 - increased LDH (rapidly progressing disease, poor prognostic factor)
- staging: CT neck, chest, abdomen, pelvis and bone marrow biopsy
- PET is useful for monitoring response to treatment and evaluation of residual tumour following therapy in aggressive histological disease
- diagnosed by
 - lymph node biopsy: excisional biopsy preferred, FNA unreliable
 - bone marrow biopsy: not optimal for diagnosis as BM involved in only 30% of high grade lymphomas

Treatment

- localized disease (e.g. GI, brain, bone, head and neck)
 - radiotherapy to primary site and adjacent nodal areas
 - adjuvant chemotherapy
 - surgery: splenic marginal zone lymphoma
- indolent lymphoma: goal of treatment is symptom management
 - watchful waiting
 - radiation therapy for localized disease
 - bendamustine plus rituximab, an anti-CD20 antibody, is superior to CHOP + rituximab (CHOP-R) for advanced stage disease (StIL trial)
- aggressive lymphoma: goal of treatment is curative
 - combination chemotherapy: CHOP is mainstay, plus rituximab if B-cell lymphoma
 - radiation for localized/bulky disease
 - CNS prophylaxis with high-dose methotrexate if certain sites involved (testicular)
 - relapse, resistant to therapy: high dose chemotherapy, autologous SCT
- highly aggressive lymphoma
 - Burkitt lymphoma: short bursts of intensive chemotherapy “CODOX-M” chemotherapy regimen also often used ± IVAC with Rituximab
 - CNS prophylaxis and tumour lysis syndrome prophylaxis

Complications

- hypersplenism
- infection
- autoimmune hemolytic anemia and thrombocytopenia
- vascular obstruction (from enlarged nodes)
- bowel perforation
- tumour lysis syndrome (particularly in very aggressive lymphoma) *see Tumour Lysis Syndrome, H52*

Prognosis

- follicular lymphoma: Follicular Lymphoma International Prognostic Index is used (5 adverse prognostic factors): age >60; >4 nodal areas; elevated LDH; Lugano stage III-IV; hemoglobin <120 g/L
 - based on calculated risk, mean 5 yr survival ranges from 53-91%
 - rarely curative, typically relapsing and remitting course with risk of transformation to aggressive lymphoma such as diffuse large B-cell lymphoma
- diffuse large B-cell lymphoma: The International Prognostic Factor Index is used (5 adverse prognostic factors): age >60; Ann Arbor stage (III-IV); performance status (ECOG/Zubrand 2-4); elevated LDH; >1 extranodal site
 - based on calculated risk, mean 5 yr survival ranges from 26-73%
 - ~40% rate of cure

Table 35. Characteristics of Select Non-Hodgkin Lymphomas

	Follicular Lymphoma	Diffuse Large B-Cell Lymphoma (DLBCL)	Burkitt Lymphoma	Mantle Cell Lymphoma
Percentage of NHLs	22-30%	33%	<1% adult NHLs 30% childhood NHLs	6%
Genetic Mutation	Bcl-2 activation	Bcl-2, Bcl-6, MYC rearrangements	c-Myc activation	Overexpression of cyclin D1 (Bcl-1 activation)
Classification	Indolent	Aggressive (high-grade)	Very aggressive	Indolent
Risk Factors	Middle-age – elderly	Previous CLL (Richter's transformation: 5% CLL patients progress to DLBCL)	1. Endemic: African origin, EBV-associated 2. Sporadic: no EBV 3. HIV-related: AIDS-defining illness	Male (M:F = 4:1)
Clinical Features	Widespread painless LAD* ± bone marrow involvement Frequent transformation to aggressive lymphoma Very responsive to chemoradiation treatment	Rapidly progressive LAD and extranodal infiltration 50% present at stage I/II, 50% widely disseminated	Endemic form: massive jaw LAD “Starry-sky” histology High risk of tumour lysis syndrome upon treatment	Often presents Stage IV with palpable LAD Involvement of GI tract (lymphomatosis polyposis), Waldenyer's Ring 5 yr survival 25%

*LAD = lymphadenopathy

Common Chemotherapeutic Regimens

CHOP: cyclophosphamide, hydroxydoxorubicin (Adriamycin®), vincristine (Oncovin®), prednisone

VAD: vincristine, adriamycin, dexamethasone

ABVD: adriamycin, bleomycin, vinblastine, dacarbazine

BEACOPP: bleomycin, etoposide, adriamycin, cyclophosphamide, vincristine, procarbazine, and prednisone

Malignant Clonal Proliferations of Mature B-Cells

Table 36. Characteristics of B-Cell Malignant Proliferation

	CLL	Lymphoplasmacytic Lymphoma	Myeloma
Cell Type	Lymphocyte	Plasmacytoid	Plasma cell
Protein	IgM if present	IgM	IgG, A, light chain (rarely M, D, or E)
Lymph Nodes	Very common	Common	Rare
Hepatosplenomegaly	Common	Common	Rare
Bone Lesions	Rare	Rare	Common
Hypercalcemia	Rare	Rare	Common
Renal Failure	Rare	Rare	Common
Immunoglobulin Complications	Common	Rare	Rare

Rouleaux formation on peripheral blood smear, if not artifact, denotes hyperglobulinemia (but not necessarily monoclonality)

Chronic Lymphocytic Leukemia

Definition

- indolent disease characterized by clonal malignancy of mature B-cells

Epidemiology

- most common leukemia in Western world
- mainly older patients; median age 70 yr
- M>F

Pathophysiology

- accumulation of neoplastic lymphocytes in blood, bone marrow, lymph nodes, and spleen

Clinical Features

- 25% asymptomatic (incidental finding)
- 5-10% present with B-symptoms (≥ 1 of: unintentional weight loss $\geq 10\%$ of body weight within previous 6 mo, temperature $>38^\circ\text{C}$ or night sweats for ≥ 2 wk without evidence of infection, extreme fatigue)
- lymphadenopathy (50-90%), splenomegaly (25-55%), hepatomegaly (15-25%)
- immune dysregulation: autoimmune hemolytic anemia (DAT positive), ITP, hypogammaglobulinemia \pm neutropenia
- bone marrow failure: late, secondary to marrow involvement by CLL cells

Investigations

- CBC: clonal population of B lymphocytes $>5 \times 10^9/\text{L}$
- peripheral blood film
 - lymphocytes are small and mature
 - smudge cells
- flow cytometry (CD5, CD20dim, CD23)
- cytogenetics: FISH (dictates response therapy and prognosis)
- bone marrow aspirate
 - lymphocytes $>30\%$ of all nucleated cells
 - infiltration of marrow by lymphocytes in 4 patterns: nodular (10%), interstitial (30%), diffuse (35%, worse prognosis), or mixed (25%)

Smudge cells are artifacts of damaged lymphocytes from slide preparation

Natural History and Treatment

- natural history: indolent and incurable; most cases show slow progression
- small minority present with aggressive disease; usually associated with chromosomal abnormalities (e.g. p53 deletion)
- first line therapy is dictated by cytogenetic status and patient co-morbidities
 - observation if early, stable, asymptomatic
 - treatment options vary by region; ideal first line therapy should include a monoclonal CD20 agent (e.g. rituximab, obinutuzumab)
 - commonly fludarabine + cyclophosphamide + rituximab (FCR) in fit patients with normal CrCl;
 - bendamustine + rituximab (BR) in less fit
 - chlorambucil + anti-CD20 obinutuzumab in the elderly
 - corticosteroids, IVIg: especially for autoimmune phenomera/radiotherapy
- molecular therapies
 - Idelalisib – PI3K inhibitor
 - Ibrutinib – BTK (Bruton's tyrosine kinase) inhibitor

Prognosis

- 9 yr median survival, but varies greatly
- prognosis predicted by Rai staging and cytogenetic status
- low risk: lymphocytosis in blood and bone marrow only
- intermediate risk: lymphocytosis with enlarged nodes in any site or splenomegaly, hepatomegaly
- high risk: lymphocytosis with disease-related anemia (<110 g/L) or thrombocytopenia (<100 x 10⁹/L)

Complications

- bone marrow failure
- immune complications: AIHA, ITP, immune deficiency (hypogammaglobulinemia, impaired T-cell function)
- polyclonal or monoclonal gammopathy (often IgM)
- hyperuricemia with treatment
- 5% undergo Richter's transformation: aggressive transformation to diffuse large B-cell lymphoma (see Table 35)

Multiple Myeloma

Definition

- neoplastic clonal proliferation of plasma cells producing a monoclonal immunoglobulin resulting in end organ dysfunction
- usually single clone of plasma cells, although biclonal myeloma also occurs; rarely non-secretory

Epidemiology

- incidence 3 per 100,000, most common plasma cell malignancy
- increased frequency with age; median age of diagnosis is 68 yr; M>F

Pathophysiology

- malignant plasma cells secrete monoclonal antibody
 - 95% produce M protein (monoclonal Ig = identical heavy chain + identical light chain, or light chains only)
 - ♦ IgG 50%, IgA 20%, IgD 2%, IgM 0.5%
 - ♦ 15-20% produce free light chains or light chains alone found in either:
 - serum as an increase in the quantity of either kappa or lambda light chain (with an abnormal kappa:lambda ratio)
 - urine has Bence-Jones protein
 - <5% are non-secretors

Clinical Features and Complications

- bone disease: pain (usually back), bony tenderness, pathologic fractures
 - lytic lesions are classical (skull, spine, proximal long bones, ribs)
 - increased bone resorption secondary to osteoclast activating factors such as PTHrP
- anemia: weakness, fatigue, pallor
 - secondary to bone marrow suppression
- weight loss
- infections
 - usually *S. pneumoniae* and Gram-negatives
 - secondary to suppression of normal plasma cell function
- hypercalcemia: N/V, confusion, constipation, polyuria, polydipsia
 - secondary to increased bone turnover
- renal disease/renal failure
 - most frequently causes cast nephropathy (see Nephrology, NP32)
- bleeding
 - secondary to thrombocytopenia, may see petechiae, purpura
 - can also be caused by acquired von Willebrand disease
- extramedullary plasmacytoma
 - soft tissue mass composed of monoclonal plasma cells, purplish colour
- hyperviscosity: may manifest as headaches, stroke, angina, MI
 - secondary to increased viscosity caused by M protein
- amyloidosis
 - accumulation of insoluble fibrillar protein (Ig light chain) in tissues; can cause infiltration of any organ system: cardiac infiltration – diastolic dysfunction, cardiac arrhythmias, syncope, sudden death; GI involvement – malabsorption, beefy large or laterally scalloped tongue; neurologic involvement – orthostatic hypotension, carpal tunnel syndrome
 - may cause Factor X deficiency if fibrils bind Factor X → bleeding (raccoon eyes)
- neurologic disease: muscle weakness, pain, paresthesias
 - radiculopathy caused by vertebral fracture, extramedullary plasmacytoma
 - spinal cord compression (10-20% of patients) is a medical emergency

Multiple Myeloma

SLiM CRAB

- Sixty percent plasma cells in bone marrow specimen
- Light chain ratio > 100
- MRI lytic lesion > 0.5 cm
- Calcium > 2.80 mmol/L
- Renal failure (Cr > 176 mmol/L)
- Anemia
- Bony lesions (lytic lesions or osteoporosis felt to be caused by myeloma)

Amyloid

The general term for a variety of proteinaceous materials that have a similar structural organization and are abnormally deposited in tissues

Found in a variety of clinical disorders and can cause systemic (e.g. MM [light chains]) or localized amyloidosis (e.g. Alzheimer disease [AB amyloid])

Investigations

- CBC
 - normocytic anemia, thrombocytopenia, leukopenia
 - rouleaux formation on peripheral film
- biochemistry
 - increased Ca^{2+} , increased ESR, decreased anion gap, increased Cr, albumin, β 2-microglobulin (as part of staging), proteinuria (24 h urine collection)
- monoclonal proteins
 - serum protein electrophoresis (SPEP): demonstrates monoclonal protein spike in serum in 80% (i.e. M protein)
 - urine protein electrophoresis (UPEP): demonstrates light chains in urine = Bence-Jones protein (15% secrete only light chains)
 - immunofixation: demonstrates M protein and identifies Ig type; also identifies light chains
 - serum free light chain quantification: kappa and lambda light chains, calculated ratio
- bone marrow aspirate and biopsy
 - often focal abnormality, greater than 10% plasma cells, abnormal morphology, clonal plasma cells; send for FISH or cytogenetics (prognostic implications)
- skeletal series (X-rays), MRI if symptoms of cord compression
 - presence of lytic lesions and areas at risk of pathologic fracture
 - bone scans are not useful since they detect osteoblast activity
- β 2-microglobulin, LDH, and CRP are poor prognosticators

Diagnosis

- International Myeloma Working Group Criteria
 1. serum or urinary monoclonal protein
 2. presence of clonal plasma cells in bone marrow (>60% without "CRAB") or a plasmacytoma
 3. presence of end-organ damage related to plasma cell dyscrasia, such as:
 - ◆ increased serum Ca^{2+}
 - ◆ lytic bone lesions
 - ◆ anemia
 - ◆ renal failure

Treatment

- treatment is non-curative
- treatment goals
 - improvement in quality of life (improve anemia, reverse renal failure, bony pain)
 - prevention of progression and complications
 - increase overall survival
- autologous stem cell transplant if <65 yr old
 - usually preceded by 4-6 mo of cytoreductive therapy: steroid based with novel agents (i.e. immunomodulatory drugs or proteasome inhibitors)
- chemotherapy if >65 yr old or transplant-ineligible
 - melphalan, prednisone, cyclophosphamide and proteasome inhibitor (i.e. bortezomib)
- dexamethasone and bortezomib if ARF; bortezomib \pm dexamethasone in light chain amyloidosis
- supportive management
 - bisphosphonates for those with osteopenia or lytic bone lesions (requires renal dosing)
 - local XRT for bone pain, spinal cord compression
 - kyphoplasty for vertebral fractures to improve pain relief and regain height
 - treat complications: hydration for hypercalcemia and renal failure, bisphosphonates for severe hypercalcemia, prophylactic antibiotics, erythropoietin for anemia, DVT prophylaxis
- all patients will relapse; choice of retreatment regimen depends on duration of remission, organ involvement, patient's comorbidities, and preferences

Prognosis

- ISS - International Staging System (β 2-microglobulin and albumin) used to stage and estimate prognosis
- revised ISS for risk stratification: combination of original ISS, cytogenetic profile (i.e. p53 mutation associated with poor survival and resistance to chemotherapy) and LDH
- median survival based on stage, usually 3-7 yr

Routine urinalysis will not detect light chains as dipstick detects albumin. Need sulfosalicylic acid or 24 h urine protein for immunofixation or electrophoresis

Light Chain Disease

15% of MM produce only light chains
Renal failure is a major problem
Kappa > lambda light chain has better prognosis

Serum Free Light Chain Ratio is an Independent Risk Factor for Progression in MGUS

Blood 2005;106:812-817

Purpose: To determine whether the presence of monoclonal free kappa or lambda immunoglobulin light chains in MGUS increases the risk of progression to malignancy.

Methods: Retrospective study with median follow-up of 15 yr. Baseline serum samples obtained from 1,383 MGUS patients seen at the Mayo clinic between 1960-1994. 1,148 baseline samples were obtained within 30 d of diagnosis.

Results: Malignant progression had occurred in 87 (7.6%) patients. In 379 (33%) patients, an abnormal serum free light chain (FLC) ratio was detected. There was a significantly higher risk of progression in patients with an abnormal FLC ratio relative to patients with a normal ratio (hazard ratio, 3.5; 95% CI 2.3-5.5; $p < 0.001$). This finding was independent of the size and type of the serum monoclonal (M) protein. In high-risk MGUS patients (abnormal serum FLC ratio, non-IgG MGUS, high serum M protein level [≥ 1.5 gm/dL]), the risk of progression at 20 yr was 58% compared to 37% in high-intermediate-risk MGUS (two risk factors), 21% low-intermediate-risk (with one risk factor) and 5% low-risk (no risk factors).

Conclusions: The presence of an abnormal FLC ratio is a clinically and statistically significant predictor of progression in MGUS. The low-risk subset of patients with MGUS accounts for 40% of all MGUS patients and have a small lifetime risk of progression, thus less follow-up can be justified.

Monoclonal Gammopathy of Unknown Significance

Definition

- presence of M protein in serum in absence of any clinical or laboratory evidence of a plasma cell dyscrasia or lymphoproliferative disorders
 - incidence: 0.15% in general population, 5% of people >70 yr of age
 - asymptomatic

Diagnosis

- presence of a serum monoclonal protein (M protein) at a concentration <30 g/L
- <10% plasma cells in bone marrow
- absence of hyperCalcemia, Renal insufficiency, Anemia, Bony disease related to the plasma cell proliferative process (absence of "CRAB")
- 0.3-1% of patients develop a hematologic malignancy each yr
 - patients with M protein peak ≥ 15 g/L or patients with IgA or IgM MGUS are at higher risk of malignant transformation
 - patients with abnormal serum free light chains ratio are at increased risk of malignant transformation
- monitor with annual history, physical, CBC, Cr, calcium, albumin, serum protein electrophoresis (considered pre-malignant)

Lymphoplasmacytic Lymphoma (Waldenstrom's Macroglobulinemia)

Definition

- proliferation of lymphoplasmacytoid cells
 - presence of monoclonal IgM paraprotein

Clinical Features

- chronic disorder of elderly patients; median age 64 yr
- symptoms: weakness, fatigue, bleeding (oronasal), weight loss, recurrent infections, dyspnea, CHF (triad of anemia, hyperviscosity, plasma volume expansion), neurological symptoms, peripheral neuropathy, cerebral dysfunction
- signs: pallor, splenomegaly, hepatomegaly, lymphadenopathy, retinal lesions
- key complication to avoid: hyperviscosity syndrome
 - because IgM (unlike IgG) confined largely to intravascular space

Investigations and Diagnosis

- bone marrow shows plasmacytoid lymphocytes
- bone lesions usually not present
- blood work rarely see hypercalcemia
- cold hemagglutinin disease possible: Raynaud's phenomenon, hemolytic anemia precipitated by cold weather
- normocytic anemia, rouleaux, high ESR if hyperviscosity not present

Treatment

- Bendamustine – R/R-CVP chemotherapy, alkylating agents (chlorambucil), nucleoside analogues (fludarabine), rituximab, or combination therapy
- corticosteroids
- plasmapheresis for hyperviscosity: acute reduction in serum IgM

Waldenstrom's macroglobulinemia accounts for 85% of all cases of hyperviscosity syndrome

Complications of Hematologic Malignancies

Hyperviscosity Syndrome

Definition

- refers to clinical sequelae of increased blood viscosity (when relative serum viscosity >5-6 units), resulting from increased circulating serum Igs or from increased cellular blood components in hyperproliferative disorders (e.g. multiple myeloma, leukemia, PV)
- Waldenstrom's macroglobulinemia accounts for 85% of cases

Clinical Features

- hypervolemia causing: CHF, headache, lethargy, dilutional anemia
- CNS symptoms due to decreased cerebral blood flow: headache, vertigo, ataxia, stroke
- retina shows venous engorgement and hemorrhages
- bleeding diathesis
 - due to impaired platelet function, absorption of soluble coagulation factors (e.g. nasal bleeding, oozing gums)
- ESR usually very low

Treatment

- plasmapheresis, chemotherapy

Tumour Lysis Syndrome

Definition

- group of metabolic complications that result from spontaneous or treatment-related breakdown of cancer cells
- more common in diseases with large tumour burden and high proliferative rate (high grade lymphoma, leukemia)

Clinical Features

- metabolic abnormalities
 - cells lyse, releasing K^+ , uric acid, PO_4^{3-} (increased levels)
 - PO_4^{3-} binds Ca^{2+} (decreased Ca^{2+})
- complications
 - lethal cardiac arrhythmia (increased K^+)
 - acute kidney injury (formerly known as renal failure) see [Nephrology, NP18](#)

Treatment

- prevention
 - aggressive IV hydration
 - alkalization not recommended due to risk of calcium phosphate or xanthine precipitation in renal tubules
 - allopurinol or rasburicase
 - correction of pre-existing metabolic abnormalities
- dialysis

Blood Products and Transfusions

Blood Products

- RBCs, platelets and coagulation factors (frozen plasma [FP], cryoprecipitate, factor concentrates) are available for transfusion
- donated blood (1 U = 450-500 mL) is fractionated into these various components
 - centrifugation separates whole blood into RBCs and platelet-rich plasma
 - platelet-rich plasma is further fractionated into platelets and plasma
 - ♦ need to pool together multiple units to obtain therapeutic amounts
 - ♦ FP (previously known as FFP) is plasma frozen within 24 h of collection
 - ♦ cryoprecipitate is the high MW precipitate generated when FP is thawed at low temperatures

Specialized Products

- irradiated blood products
 - prevent proliferation of donor T-cells in potential or actual bone marrow transplant recipients
 - used for immunocompromised patients or for patients on purine analogue chemotherapy, first-degree relatives, HLA-matched products and intrauterine transfusions, Hodgkin lymphoma
- CMV-negative blood products
 - potential transplant recipients
 - neonates
 - AIDS patients
 - seronegative pregnant women

Blood Groups

Group	Antigen (on RBC)	Antibody (in serum)
O	H	Anti-A, anti-B
A	A	Anti-B
B	B	Anti-A
AB	A and B	Nil

In Canada, blood products are leukodepleted via filtration immediately after donation; therefore it is considered:

- Low in lymphokines, resulting in a lower incidence of febrile nonhemolytic transfusion reactions
- CMV negative (because CMV is found in leukocytes)

1 unit of pRBC will increase Hb by approximately 10 g/L or increase Hct by 4%

American Society of Hematology Choosing Wisely Recommendation

Do not transfuse more than the minimum number of RBC units necessary to relieve symptoms of anemia or to return the patient to a safe hemoglobin range (70-80 g/L) in stable non-cardiac patients

Red Blood Cells

Packed Red Blood Cells

- stored at 4°C
- transfuse within 42 d of collection, otherwise cell lysis may result in hyperkalemia
- infuse each unit over 2 h (max of 4 h)

Indications for Packed RBC Transfusion

- Hb <70 g/L; this may change as per patient's tolerance or symptoms
 - maintain Hb between 70 and 100 g/L during active bleeds
- consider maintaining a higher Hb for patients with:
 - CAD/unstable coronary syndromes
 - uncontrolled, unpredictable bleeding
 - impaired pulmonary function
 - increased O_2 consumption

Selection of Red Cells for Transfusion

- when anticipating an RBC transfusion, the following should be ordered:
 - group and screen: determines the blood group and Rh status of the recipient as well as the presence of autoantibodies vs. major/minor blood group antigens in the patient's serum
 - cross-match: involves mixing the recipient's blood with potential donor blood and looking for agglutination (takes 30-45 min)
- when blood is required, several options are available
 - 1st line: fully crossmatched blood, electronic crossmatch is becoming more widely used (not always available in emergency situations)
 - 2nd line: donor blood of the same group and Rh status as the recipient
 - 3rd line: O- blood for females of reproductive age; O+ blood for all others

Transfusion Requirements in Critical Care (TRICC)

NEJM 1999;340:409-417

Study: Multicentre, RCT.

Participants: 838 critically ill patients with euvoemia after initial treatment and hemoglobin less than 9 g/dL within 72 h of ICU admission.

Intervention: Patients receiving a transfusion followed either (1) a restrictive strategy (RS; n=418) in which red cells were transfused if hemoglobin was less than 7.0 g/dL and then maintained at 7 to 9 g/dL or (2) a liberal strategy (LS; n=420) in which transfusions occurred when the hemoglobin was less than 10.0 g/dL and then maintained at 10 to 12 g/dL.

Primary Outcome: Mortality at 30 d and severity of organ dysfunction.

Results: Mortality rates at 30 d were similar between groups. However, mortality rates were significantly lower with the RS among less acutely ill patients (8.7% and RS group and 16.1% in LS group; p=0.03) and among those <55 yr of age (5.7% RS and 13% LS; p=0.02), but did not differ in a subgroup with clinically significant cardiac disease.

Conclusion: A RS of red cell transfusion is at least as effective as, and possibly superior to, a LS transfusion in critically ill patients.

Liberal or Restrictive Transfusion in High-Risk Patients After Hip Surgery (FOCUS)

NEJM 2011;365:2453-2462

Study: Multicentre RCT.

Participants: 2,016 patients aged greater than 50 yr with a history of or risk factors for cardiovascular disease and hemoglobin (Hb) level below 10 g/dL after hip-fracture surgery.

Intervention: Patients were randomly assigned to a liberal transfusion strategy (a Hb threshold of 10 g/dL) or a restrictive transfusion strategy (anemia symptoms or at physician discretion for a Hb level less than 8 g/dL).

Primary Outcome: Mortality or inability to walk across a room without human assistance on a 60 day follow-up.

Results: Primary outcome rates were 35.2% in the liberal transfusion strategy group and 34.7% in the restrictive transfusion strategy group. Rates of complications were similar in the two groups.

Conclusion: A liberal transfusion strategy did not reduce mortality rates or the inability to walk independently on 60 d follow-up compared to a restrictive transfusion strategy in elderly patients with high cardiovascular risk factors after hip surgery.

Platelets

Table 37. Platelet Products

Product	Indication
Random Donor (Pooled)	Thrombocytopenia with bleeding
Single Donor Platelets	Potential BMT recipients
HLA Matched Platelets	Refractory to pooled or single donor platelets, presence of HLA antibodies

- stored at 20-24°C
- random donor platelets are transfused from a pool of 4 units; this should increase the platelet count by $\geq 15 \times 10^9/L$
- single donor platelets (transfused as single units) should increase the platelet count by 40-60 $\times 10^9/L$
- if an increase in the platelet count is not seen post-transfusion: autoantibodies (i.e. ITP), alloantibodies, consumption (bleeding, sepsis), or hypersplenism may be present

Table 38. Indications for Platelet Transfusion

Plt ($\times 10^9/L$)	Indications
<10	Non-immune thrombocytopenia
<20	Procedures not associated with significant blood loss
<50	Procedures associated with blood loss or major surgery (>500 mL EBL)
<100	Pre-neurosurgery or head trauma
Any	Platelet dysfunction (or antiplatelet agents) and marked bleeding

Relative Contraindications of Platelet Transfusion

- TTP, HIT, post-transfusion purpura, HELLP

Coagulation Factors

Table 39. Coagulation Factor Products

Product	Indication
Frozen plasma (FP)	Depletion of multiple coagulation factors (e.g. sepsis, DIC, dilution, TTP/HUS, liver disease), emergency reversal of life-threatening bleeding secondary to warfarin overdose
Cryoprecipitate (enriched fibrinogen, vWF, VIII, XIII)	Hemophilia A (Factor VIII deficiency) – use in emergencies von Willebrand disease – use in emergencies Hypofibrinogenemia
Humate P or Wilate	von Willebrand disease Hemophilia A
Factor VIII concentrate	Factor VIII deficiency (Hemophilia A)
Factor IX concentrate	Factor IX deficiency (Hemophilia B)
Recombinant factor VIIa	Factor VII deficiency with bleeding/surgery, Hemophilia A or B with inhibitors, Glanzmann thrombasthenia
Prothrombin complex concentrate; PCC (Octaplex®, Beriplex®)	Reversal of warfarin therapy or vitamin K deficiency in bleeding patient or in patient requiring urgent (<6 h) surgical procedure, urgent non-specific “reversal” of direct Xa inhibitors
Activated prothrombin complex concentrate; aPCC (FEIBA)	Hemophilia A or B with inhibitors, urgent non-specific “reversal” of direct thrombin inhibitors

Acute Blood Transfusion Reactions

IMMUNE

Acute Hemolytic Transfusion Reactions

- ABO incompatibility resulting in intravascular hemolysis secondary to complement activation, occurs immediately after transfusion
- most commonly due to incorrect patient identification
- risk per unit of blood is <1 in 40,000
- presentation: fever, chills, hypotension, back or flank pain, dyspnea, hemoglobinuria
- acute renal failure (<24 h) and DIC
- treatment
 - stop transfusion
 - notify blood bank and check for clerical error
 - maintain BP with vigorous IV fluids \pm inotropes
 - maintain urine output with diuretics, crystalloids, dopamine

Febrile Nonhemolytic Transfusion Reactions

- due to alloantibodies to WBC, platelets or other donor plasma antigens, and release of cytokines from blood product cells
- occurs within 0-6 h of transfusion
- risk per unit of blood is 1 in 100 (minor), 1 in 10,000 to 40,000 (severe)
- presents with fever \pm rigors, facial flushing, headache, myalgia, hypotension
- treatment
 - rule out hemolytic reaction or infection
 - if temperature $<38^{\circ}\text{C}$, continue with transfusion but decrease rate and give antipyretics
 - if temperature $>38^{\circ}\text{C}$, stop transfusion, give antipyretics and anti-histamine

Allergic Nonhemolytic Transfusion Reactions

- alloantibodies (IgE) to proteins in donor plasma result in mast cell activation and release of histamine
- occurs mainly in those with history of multiple transfusions or multiparous women
- risk per unit of blood is 1 in 100
- presents mainly as urticaria and occasionally with fever
- can present as anaphylactoid reaction with bronchospasm, laryngeal edema, and hypotension, but this occurs mainly in IgA deficient patients that have anti-IgA antibodies
- treatment
 - mild: slow transfusion rate and give diphenhydramine
 - moderate to severe: stop transfusion, give IV diphenhydramine, steroids, epinephrine, IV fluids, and bronchodilators

Transfusion-Related Acute Lung Injury

- new-onset acute lung injury that occurs during transfusion or within 6 h of transfusion completion
 - insidious, acute onset of pulmonary insufficiency
 - profound hypoxemia ($\text{PaO}_2/\text{FiO}_2 < 300$ mmHg)
 - bilateral pulmonary edema on CXR
 - pulmonary artery wedge pressure <18 mmHg
 - no clinical evidence of left atrial hypertension
- pathogenesis uncertain; perhaps due to binding of donor antibodies to WBC of recipient and release of mediators that increase capillary permeability in the lungs
- typically occurs 2-4 h post transfusion and resolves in 24-72 h
- risk per unit of blood is 1 in 10,000
 - is currently the leading cause of transfusion-related morbidity and mortality
- treatment: supportive therapy (oxygen)
- inform blood bank; patient and donor testing will be arranged

NONIMMUNE

Transfusion-Associated Circulatory Overload

- due to impaired cardiac function and/or excessive rapid transfusion
- presentation: dyspnea, orthopnea, hypotension, tachycardia, crackles at base of lung, and increased venous pressure
- incidence: 1 in 700 and is becoming more common
- treatment: transfuse at lower rate, give diuretics and oxygen

Bacterial Infection

- Gram-positive: *S. aureus*, *S. epidermidis*, *Bacillus cereus*
- Gram-negative: *Klebsiella*, *Serratia*, *Pseudomonas*, *Yersinia*
- overall risk is 1 in 100,000 for RBC and 1 in 10,000 for platelets
- never store blood >4 h after bag has left blood bank
- treatment: stop transfusion, blood cultures, IV antibiotics, fluids

DDx of Post-Transfusion Fever

- Acute hemolytic transfusion reaction
- Febrile non-hemolytic transfusion reaction
- Bacterial contamination
- Allergy

DDx of Post-Transfusion Dyspnea

- Transfusion-associated circulatory overload (TACO)
- Transfusion-related acute lung injury (TRALI)
- Allergy (bronchospasm/anaphylaxis)

Hyperkalemia

- due to K^+ release from stored RBC
- risk increases with storage time and if blood is irradiated and risk decreases if given fresh blood
- occurs in 5% of massively transfused patients
- treatment: see [Nephrology, NP13](#)

**Citrate Toxicity**

- occurs with massive transfusion in patients with liver disease – patients are unable to clear citrate from blood
- citrate binds to Ca^{2+} and causes signs and symptoms of hypocalcemia
- treatment: IV calcium gluconate (10 mL for every 2 units of blood)

Dilutional Coagulopathy

- occurs with massive transfusion (>10 units)
- pRBC contains no clotting factors, fibrinogen, cryoprecipitate, or platelets
- treatment: FP, cryoprecipitate, and platelets

Delayed Blood Transfusion Reactions

IMMUNE**Delayed Hemolytic**

- due to alloantibodies to minor antigens such as Rh, Kell, Duffy, and Kidd
- level of antibody at time of transfusion is too low to cause hemolysis; later the level of antibody increases due to secondary stimulus and causes extravascular hemolysis
- occurs 5-7 d after transfusion
- presentation: anemia and mild jaundice
- treatment: no specific treatment required; important to note for future transfusion
- N.B. serologic transfusion reactions are the development of alloantibodies in the absence of frank hemolysis

Transfusion-Associated Graft Versus Host Disease

- transfused T-lymphocytes recognize and react against “host” (recipient)
- occurs 4-30 d following transfusion
- most patients already have severely impaired immune systems (e.g. Hodgkin lymphoma or leukemia)
- presentation: fever, diarrhea, liver function abnormalities, and pancytopenia
- can be prevented by giving irradiated blood products

NONIMMUNE**Iron Overload**

- due to repeated transfusions over long period of time (e.g. β -thalassemia major)
- can cause secondary hemochromatosis
- treatment: iron chelators or phlebotomy if no longer requiring blood transfusion and not anemic

Viral Infection Risk

- HBV 1 in 1.1 to 1.7 million
- HCV 1 in 5 to 7 million
- HIV 1 in 8 to 12 million
- Human T-lymphotropic virus (HTLV) 1 in 1 to 1.3 million
- other infections include EBV, CMV, WNV (West Nile virus)

Common Medications

Antiplatelet Therapy

• see Figure 11a, Platelet Activation Cascade, H26

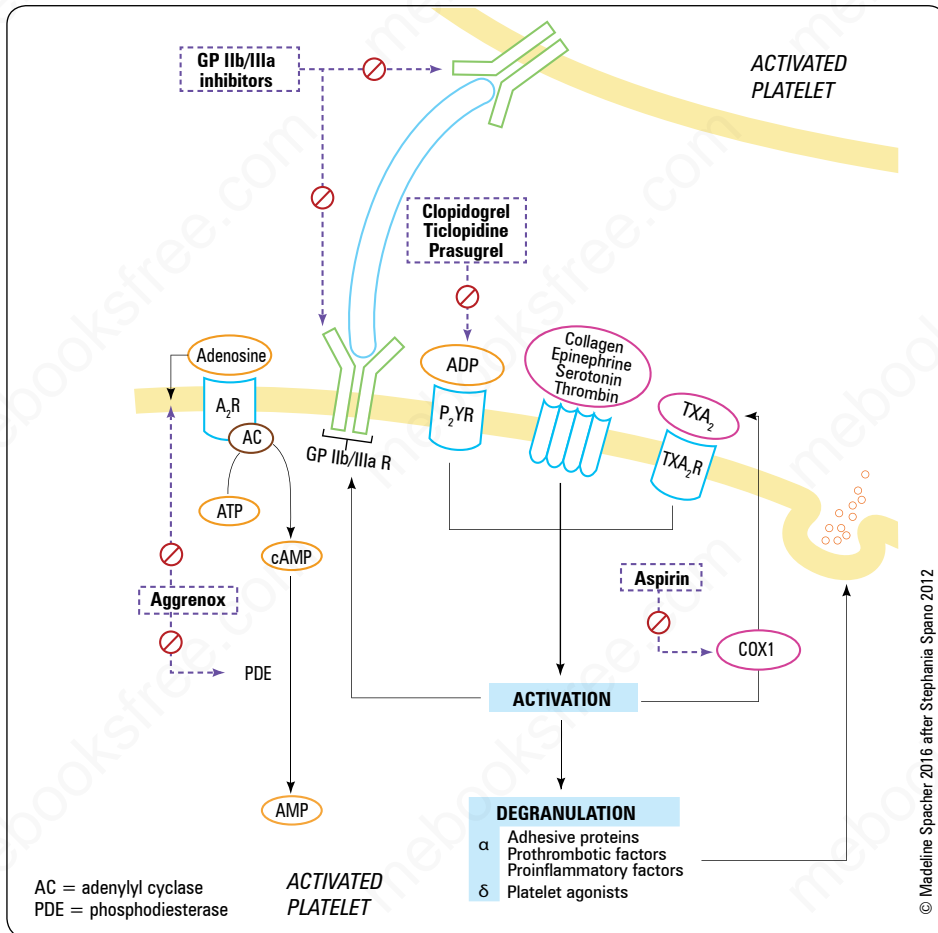

Figure 15. Mechanisms of action of antiplatelet therapy

Table 40. Antiplatelet Therapy

	Mechanism of Action	Dose/Route of Administration	Onset/Peak/Duration	Specific Side Effects	Remarks
Aspirin® (ASA)	Irreversibly acetylates COX, inhibiting TXA ₂ synthesis, thus inhibiting platelet aggregation	Single loading 200-300 mg PO, followed by dose of 75-100 mg PO daily	Onset: 5-30 min Peak: 0.25-3 h Duration: 3-6 h	GI ulcer/bleeding Tinnitus Bronchospasm Angioedema Reye's syndrome in pediatric patients	Indicated for stroke/MI prophylaxis Reduce incidence of recurrent MI Decrease mortality in post-MI patients Contraindicated in patients with GI ulcers
Aggrenox® (ASA + Dipyridamole)	Dipyridamole increases intracellular cAMP levels, which inhibits TXA ₂ synthesis, leading to decreased platelet aggregation	1 capsule PO bid	Peak: 75 min	H/A Dyspepsia N/V Abdominal pain Cardiac failure Hemorrhoids	More effective than ASA in secondary prevention of stroke Dipyridamole potentiates antiplatelet action of ASA
Clopidogrel (Plavix®)	Irreversibly inhibit ADP binding to platelets, thus decreased platelet aggregation	75-300 mg PO daily	Onset: 2 h Peak: 1 h	URI Chest pain H/A Flu-like syndrome Depression UTI GI hemorrhage Pancytopenia May cause TTP	Prevention of cardiovascular events in high-risk patients Clopidogrel is a prodrug requiring two-step activation to active metabolite CYP2C19 poor metabolizers have diminished response to clopidogrel Caution with hepatic/renal impairment
Prasugrel (Effient®)	Same as clopidogrel	5-10 mg PO daily	Onset: 30 min	Dizziness H/A Nervousness Blurry vision	Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel No significant drug-drug interaction, although more data is required

Table 40. Antiplatelet Therapy (continued)

	Mechanism of Action	Dose/Route of Administration	Onset/Peak/Duration	Specific Side Effects	Remarks
Ticagrelor (Brilinta®)	Reversibly inhibit ADP binding to platelets	90 mg PO daily	Onset: 1.5 h for prodrug, 2.5 h for active metabolite	Difficulty or laboured breathing Shortness of breath Tightness in chest Dizziness	Alternative to clopidogrel for prevention of cardiovascular events in high-risk patients Higher potency compared to clopidogrel Ticagrelor is a prodrug that requires CYP3A4-mediated activation to active metabolite Drug-drug interactions with CYP3A4 inhibitors and inducers
Glycoprotein IIb/IIIa Inhibitors (Reopro® [abciximab], Integrelin® [eptif])	Blocking GP II/IIIa receptor inhibits fibrinogen and vWF binding, leading to decreased platelet aggregation	Variable IV	Variable	Hypotension Back pain N/V Chest pain Abdominal pain Thrombocytopenia	Used most commonly in cardiac catheterization Contraindicated in PUD Monitoring aPTT/activated clotting time

Anticoagulant Therapy

Table 41. Anticoagulant Therapy

	Mechanism of Action	Dose/Route of Administration	Onset/Peak/Duration	Reversing Agent	Monitoring	Specific Side Effects	Remarks
Heparin	Accelerates inhibitory activity of antithrombin	As per hospital nomogram	Onset: 20-60 min Peak: 2-4 h	Protamine sulfate	aPTT (intrinsic pathway), UFH (anti-Xa) levels	Hemorrhage HIT Increased liver enzymes	Pregnancy: safe (does not cross placenta)
Warfarin	Vitamin K antagonist: inhibits production of II, VII, IX, X, proteins C and S	Individualized dosing by monitoring PT/INR PO	Onset: 36-48 h Peak: 1.5-3 d	IV vitamin K PCC FP	PT/INR maintain 2-3 (2.5-3.5 for mechanical valves)	Hemorrhage Cholesterol embolism syndrome Intraocular hemorrhage	Pregnancy: not used, can cross placenta (teratogenic)
LMWH (enoxaparin, dalteparin, tinzaparin)	Inhibits FXa	Variable SC/IV	Onset: 3-5 h Peak: 3-5 h Duration: 12 h	Partial reversibility with protamine sulfate	FXa in pediatrics, pregnancy and weight > 150 kg	Hemorrhage Fever Increased liver enzymes < 1% HIT	Increased bioavailability than heparin Can accumulate in patients low CrCl (< 30 mL/min)
Fondaparinux	Indirect inhibitor of FXa (through antithrombin)	Variable SC daily	Onset: 2 h Peak: 2-3 h	Not reversible	None	Anemia Fever Nausea Rash	Heparin analogue Contraindicated in renal failure
Rivaroxaban	Direct FXa inhibitor	PO	Peak: 2-4 h	Not reversible	None	Syncope GI hemorrhage	Indicated in treatment of acute VTE (non-cancer patients), secondary VTE prevention, thromboprophylaxis in orthopedic patients and stroke prophylaxis in non-valvular AFib; ensure CrCl > 30 mL/min
Apixaban	Direct FXa inhibitor	PO	Onset: 3-4h Peak: 3-4 h	Not reversible	None	Hemorrhage Nausea Anemia	Indicated for stroke prophylaxis in non-valvular AFib; Idiopathic VTE; ensure CrCl > 30
Argatroban	Direct thrombin inhibitor	Variable IV	Onset: 5-10 min Duration: 20-40 min	Not reversible	aPTT	Dyspnea Hypotension Fever	Indicated for HIT and heparin resistance in the presence renal failure
Dabigatran	Direct thrombin inhibitor	150 mg PO bid	Peak: 1 h	Not reversible	None (prolonged aPTT can suggest residual drug on board)	GI upset Dyspepsia	Only indicated for AFib in Canada Contraindicated in renal failure, cancer patients, mechanical heart valves

Adverse Reactions of Heparin

- hemorrhage: depends on dose, age, and concomitant use of antiplatelet agents or thrombolytics
- heparin-induced thrombocytopenia: associated with venous or arterial thrombosis (see Table 22, H29)
- osteoporosis: with long-term use

Low Molecular Weight Heparin (enoxaparin, dalteparin, tinzaparin)

- increased bioavailability compared to normal heparin
- increased duration of action
- SC route of administration
- do not need to monitor aPTT
- adverse reactions less common than UFH
- patients with renal failure (CrCl < 30 mL/min) can accumulate LMWH, therefore must adjust dose
- only partially reversible with protamine sulfate
- HIT is less common

Table 42. Recommended Therapeutic INR Ranges of Common Indications for Oral Anticoagulant Therapy

Indication	INR Range
Prophylaxis of venous thrombosis (high-risk surgery)	2.0-3.0
Treatment of venous thrombosis	
Most cases of thrombosis with antiphospholipid antibody syndrome	
Treatment of pulmonary embolism	
Prevention of systemic embolism	
Tissue heart valves	
AMI (to prevent systemic embolism)	
Valvular heart disease	
Atrial fibrillation	
Bileaflet mechanical valve in aortic position	
Mechanical prosthetic mitral valves (high risk)	2.5-3.5

AMI = acute myocardial infarction

Table 43. Recommended Management of a Supratherapeutic INR

INR	Bleeding Present	Recommended Action
>Therapeutic to 4.5	No	Lower warfarin dose OR Omit a dose and resume warfarin at a lower dose when INR is in therapeutic range OR No dose reduction needed if INR is minimally prolonged
>4.5 to 10.0	No	Omit the next 1 to 2 doses of warfarin, monitor INR more frequently and resume treatment at a lower dose when INR is in therapeutic range OR Omit a dose and administer 1 to 2.5 mg oral vit K in patients with increased risk of bleeding
>10.0	No	Hold warfarin and administer 5 to 10 mg oral vit K; monitor INR more frequently and administer more vit K as needed; resume warfarin at a lower dose when INR is in therapeutic range
Any	Serious or life threatening	Hold warfarin and administer 10 mg vit K by slow IV infusion; supplement with four-factor prothrombin complex concentrate; monitor and repeat as needed

Chemotherapeutic and Biologic Agents Used in Oncology

Table 44. Selected Chemotherapeutic and Biologic Agents

Class	Example	Mechanism of Action or Target
Alkylating Agent	<ul style="list-style-type: none"> chlorambucil, cyclophosphamide, melphalan (nitrogen mustards) carboplatin, cisplatin dacarbazine, procarbazine busulfan bendamustine 	Damage DNA via alkylation of base pairs Leads to cross-linking of bases, abnormal base-pairing, DNA breakage
Antimetabolites	<ul style="list-style-type: none"> methotrexate (folic acid antagonist) 6-mercaptopurine, fludarabine (purine antagonist) 5-fluorouracil (5-FU) (pyrimidine antagonist) hydroxyurea cytarabine 	Inhibit DNA synthesis
Antibiotics	<ul style="list-style-type: none"> adriamycin (anthracycline) bleomycin mitomycin C daunorubicin 	Interfere with DNA and RNA synthesis
Taxanes	<ul style="list-style-type: none"> paclitaxel docetaxel 	Stabilize microtubules against breakdown once cell division complete
Vinca-alkaloids	<ul style="list-style-type: none"> vinblastine vincristine vinorelbine 	Inhibit microtubule assembly (mitotic spindles), blocking cell division
Topoisomerase Inhibitors	<ul style="list-style-type: none"> irinotecan, topotecan (topo I) etoposide (topo II) 	Interfere with DNA unwinding necessary for normal replication and transcription
Steroids	<ul style="list-style-type: none"> prednisone dexamethasone 	Immunosuppression
Purine Analogues	<ul style="list-style-type: none"> fludarabine cladribine 	Interferes with DNA synthesis
Monoclonal Antibodies	<ul style="list-style-type: none"> trastuzumab (Herceptin®) bevacizumab (Avastin®) rituximab (Rituxan®), ofatumumab (Arzerra®), obinutuzumab (Gazyva®) cetuximab (Erbix®) 	HER2 antagonist VEGF antagonist CD20 antagonist EGFR antagonist
Small Molecule Inhibitors	<ul style="list-style-type: none"> imatinib mesylate (Gleevec®) dasatinib nilotinib erlotinib (Tarceva®) gefitinib (Iressa®) bortezomib (Velcade®) sunitinib (Sutent®) ibrutinib (Imbruvica®) idealtasib (Zydelig®) ruxolitinib (Jakavi®) 	<i>Bcr-Abl</i> inhibitor <i>Bcr-Abl</i> inhibitor <i>Bcr-Abl</i> inhibitor EGFR antagonist EGFR antagonist 26S proteasome inhibitor VEGFR, PDGFR antagonist BTK inhibitor P13K inhibitor JAK2 inhibitor

Landmark Hematology Trials

Trial	Reference	Results
Hematologic Malignancies and Related Disorders		
Hodgkin Lymphoma: ABVD vs. MOPP	<i>NEJM</i> 1992;327:1478-84	In Hodgkin lymphoma, ABVD regimen has equal failure-free and overall survival to MOPP + ABVD, but less myelotoxicity; ABVD is standard chemotherapy for Hodgkin lymphoma
CHOP	<i>NEJM</i> 1993;328:1002-6	In NHL, CHOP has lowest incidence of fatal toxic reactions and shows no significant difference from 3 other regimens in response or disease-free/overall survival; CHOP is the standard for advanced NHL
R-CHOP	<i>NEJM</i> 2002;346:235-42	Addition of rituximab to CHOP increases complete response rate and prolongs event-free survival and overall survival in elderly with DLBCL
CML: Imatinib vs. IFN + Cytarabine	<i>NEJM</i> 2003;348:994-1004	In patients with chronic-phase CML, imatinib was more effective than IFN α + cytarabine in inducing cytogenetic response and freedom from progression to accelerated phase/blast crisis
AZA-001	<i>Lancet Oncol</i> 2009;10:223-32	Azacitidine increases overall survival in higher-risk myelodysplastic syndrome than conventional care
CLL8	<i>Lancet</i> 2010;376:1164-74	Rituximab plus fludarabine and cyclophosphamide (FCR) improves progression-free and overall survival compared with fludarabine and cyclophosphamide alone (FC) in the treatment of CLL
VISTA	<i>JCO</i> 2010;28:2259-66	Bortezomib plus melphalan and prednisone (MPV) is superior to melphalan and prednisone (MP) in overall survival of non-transplant-eligible multiple myeloma patients
MIInT Group	<i>Lancet</i> 2011;12:1013-1022	Rituximab added to CHOP-like chemotherapy improved long-term outcomes for young patients with good-prognosis DLBCL
StIL	<i>Lancet</i> 2013;381(9873):1203-10	Bendamustine plus rituximab is superior to R-CHOP in terms of progression-free survival and fewer toxic effects in patients with previously untreated indolent lymphoma
Ibrutinib vs. Ofatumumab in previously treated CLL	<i>NEJM</i> 2014;371:213-223	Ibrutinib, as compared with ofatumumab, significantly improved progression-free survival, overall survival, and response rate among patients with previously treated CLL or SLL
Thrombosis		
CLOT	<i>NEJM</i> 2003;349:146-53	In patients with cancer and acute venous thromboembolism, LWMH was more effective than warfarin in reducing the risk of recurrent thromboembolism without increasing the risk of bleeding
PT1	<i>NEJM</i> 2005;353:85-6	Hydroxyurea plus low-dose ASA is superior to anagrelide plus low-dose ASA for patients with essential thrombocythemia at high risk for vascular events
ESPIRIT	<i>Lancet</i> 2006;367:1665-73	ASA plus dipyridamole is recommended over ASA alone as antithrombotic therapy after cerebral ischemia of arterial origin
Dabigatran vs. Warfarin in VTE	<i>NEJM</i> 2009;361:2342-52	In the treatment of venous thromboembolism, dabigatran is as effective as warfarin and also has a similar safety profile; note: many problems in the trial, making it less pivotal in having drug approval
EINSTEIN-PE	<i>NEJM</i> 2012;366:1287-1297	Among patients with acute PE, rivaroxaban is noninferior to warfarin in preventing recurrent VTE, and is associated with similar bleeding rates
AMPLIFY	<i>NEJM</i> 2013;369:799-808	In patients with VTE who have completed 6-12 months of anticoagulation, long-term apixaban treatment reduces recurrent VTE or all-cause mortality without increasing rates of major bleeding.
RE-VERSE AD	<i>NEJM</i> 2015;373:511-520	Idarucizumab for dabigatran reversal
Blood Products and Transfusion		
Platelet Transfusion Threshold	<i>NEJM</i> 1997;337:1870-5	The risk of major bleeding in patients with AML undergoing induction chemotherapy was similar whether the platelet-transfusion threshold was set at 20 or 10; use of the lower threshold reduced platelet usage by 21.5%
TRICC BP	<i>NEJM</i> 1999;340:409-17	A restrictive strategy of red-cell transfusion (when Hb <70) is at least as effective as and possibly superior to a liberal transfusion strategy (when Hb <100) in ICU patients; one possible exception is patients with an acute MI or unstable angina
Dose of Platelet Transfusion	<i>NEJM</i> 2010;362:600-13	Low dose prophylactic platelet transfusion decreases total number of platelets transfused but increases number of transfusions but not incidence of bleeding in patients with hypoproliferative thrombocytopenia
Transfusion in High-Risk Patients after Hip Surgery	<i>NEJM</i> 2011;365:2453-2462	A liberal transfusion strategy (Hb <100), as compared with a restrictive strategy (anemia symptoms or at physician discretion for Hb <80), did not reduce rates of death or inability to walk independently on 60-day follow-up or reduce in-hospital morbidity in elderly patients at high cardiovascular risk
Therapeutic Platelet Transfusion	<i>Lancet</i> 2012;380:1309-16	Therapeutic platelet transfusions (when bleeding occurs) may be used if severe bleeding can be identified early in autologous stem-cell transplant patients; prophylactic transfusion (when platelets <10) should remain standard of care in AML patients
Transfusion Strategies for Acute Upper GI Bleeding	<i>NEJM</i> 2013;368:11-21	As compared with a liberal transfusion strategy (Hb <90), a restrictive strategy (Hb <70) significantly improved outcomes in patients with acute upper gastrointestinal bleeding
Other		
MSH	<i>NEJM</i> 1995;332:1317-22	Hydroxyurea is effective in reduction of complications and clinical manifestations of sickle cell disease
ITP: Dexamethasone	<i>NEJM</i> 2003;349:831-6	A four-day course of high-dose dexamethasone is effective initial therapy for adults with immune thrombocytopenic purpura
CRASH-2	<i>Health Technol Assess</i> 2013; 17(10):1-79	Early administration of TXA safely reduced the risk of death in bleeding trauma patients and is highly cost-effective. Treatment beyond 3 hours of injury is unlikely to be effective

Principles of Microbiology

Bacteriology

Bacteria Basics

- bacteria are prokaryotic cells that divide asexually by binary fission
- Gram stain divides most bacteria into two groups based on their cell wall
 - Gram positive (GP): thick, rigid layer of peptidoglycan
 - Gram negative (GN): thin peptidoglycan layer + thicker outer membrane composed of lipoproteins and lipopolysaccharides
 - clinical significance: GN thick outer membrane makes it resistant to penicillin's mechanism of action
- acid-fast bacilli (AFB): high mycolic acid content in cell wall, "acid fast" as washout phase with acid-alcohol is ineffective in acid-fast bacteria,
 - e.g. *Mycobacteria*, *Nocardia*
- "atypical" bacteria: not seen on Gram stain and difficult to culture
 - obligate intracellular bacteria: e.g. *Chlamydia*, *Chlamydomphilia*
 - bacteria lacking a cell wall: e.g. *Mycoplasma*
 - spirochetes: e.g. *Treponema pallidum*
- O₂ can be either vital or detrimental to growth
 - obligate aerobes: require O₂
 - obligate anaerobes: require environment without O₂
 - facultative anaerobes: can survive in environments with or without O₂

Mechanisms of Bacterial Disease

- adherence to and colonization of skin or mucous membranes
 - fimbriae (pili): microfilaments extending through the cell wall attach to epithelial cells (e.g. *E. coli* in the urinary tract)
- invasion or crossing epithelial barriers
- evasion of host defense system through inhibition of
 - phagocytic uptake via polysaccharide capsule (e.g. *S. pneumoniae*, *N. meningitidis*, *H. influenzae*) or surface proteins (e.g. *Staphylococcus*, *Streptococcus*)
- toxin production
 - exotoxins are secreted by living pathogenic bacteria and cause disease even if the bacteria is not present (e.g. *Clostridium*)
 - endotoxins are structural components of GN bacterial cell walls, and may be shed by live cells or released during cell lysis
- intracellular growth
 - obligate intracellular: Rickettsia, *Chlamydia*, *Chlamydomphilia*
 - facultative intracellular: *Salmonella*, *Neisseria*, *Brucella*, *Mycobacteria*, *Listeria*, *Legionella*
- biofilm
 - an extracellular polysaccharide network forming mesh around the bacteria (e.g. *S. epidermidis*) which can coat prosthetic devices such as IV catheters

Table 1. Common Bacteria

	Gram-Positive Bacteria		Gram-Negative Bacteria		Not Seen on Gram Stain	
	Cocci	Bacilli (rods)	Diplococci	Bacilli (rods)	Acid Fast	Others
Aerobes	<i>Staphylococcus</i> <i>S. aureus</i> <i>S. saprophyticus</i> <i>S. epidermidis</i> <i>Streptococcus</i> <i>S. pneumoniae</i> <i>S. pyogenes</i> (GAS) <i>S. agalactiae</i> (GBS) <i>Enterococcus</i> <i>E. faecalis</i>	<i>Bacillus</i> <i>B. anthracis</i> <i>Listeria</i> <i>Nocardia</i> (modified acid-fast positive)	<i>Neisseria</i> <i>N. meningitidis</i> <i>N. gonorrhoeae</i> <i>Moraxella</i> <i>M. catarrhalis</i>	<i>Enterobacteriaceae</i> <i>E. coli</i> <i>Salmonella</i> <i>Shigella</i> <i>Campylobacter</i> <i>Yersinia</i> <i>Klebsiella</i> <i>Legionella</i> <i>Pseudomonas</i> <i>Haemophilus</i> <i>H. influenzae</i>	<i>Mycobacteria</i> <i>M. tuberculosis</i> <i>M. leprae</i> <i>M. avium</i> complex <i>M. bovis</i>	Obligative intracellular <i>Rickettsiae</i> <i>Chlamydia</i> <i>C. trachomatis</i> <i>Chlamydomphila</i> <i>C. pneumoniae</i> No cell wall <i>Mycoplasma</i> Spirochaete (spiral) <i>Treponema pallidum</i>
Anaerobes	<i>Peptostreptococcus</i>	<i>Clostridium</i> <i>C. difficile</i> <i>C. tetani</i> <i>C. botulinum</i> <i>C. perfringens</i>		<i>Bacteroides</i> <i>B. fragilis</i>		

Table 2. Commensal Flora

Site	Organisms
Skin	Coagulase-negative staphylococci, <i>Corynebacterium</i> , <i>Propionibacterium acnes</i> , <i>Bacillus</i> , <i>S. aureus</i>
Oropharynx	Viridans group streptococci, <i>Haemophilus</i> , <i>Neisseria</i> , anaerobes (<i>Peptostreptococcus</i> , <i>Bacteroides</i> , <i>Veillonella</i> , <i>Fusobacterium</i> , <i>Actinomyces</i> , <i>Prevotella</i>)
Small Bowel	<i>E. coli</i> , anaerobes (low numbers)
Colon	<i>E. coli</i> , <i>Klebsiella</i> , <i>Enterobacter</i> , <i>Enterococcus</i> , anaerobes (<i>Bacteroides</i> , <i>Peptostreptococcus</i> , <i>Clostridium</i>)
Vagina	<i>Lactobacillus acidophilus</i> , viridans group streptococci, coagulase-negative staphylococci, facultative Gram-negative bacilli, anaerobes

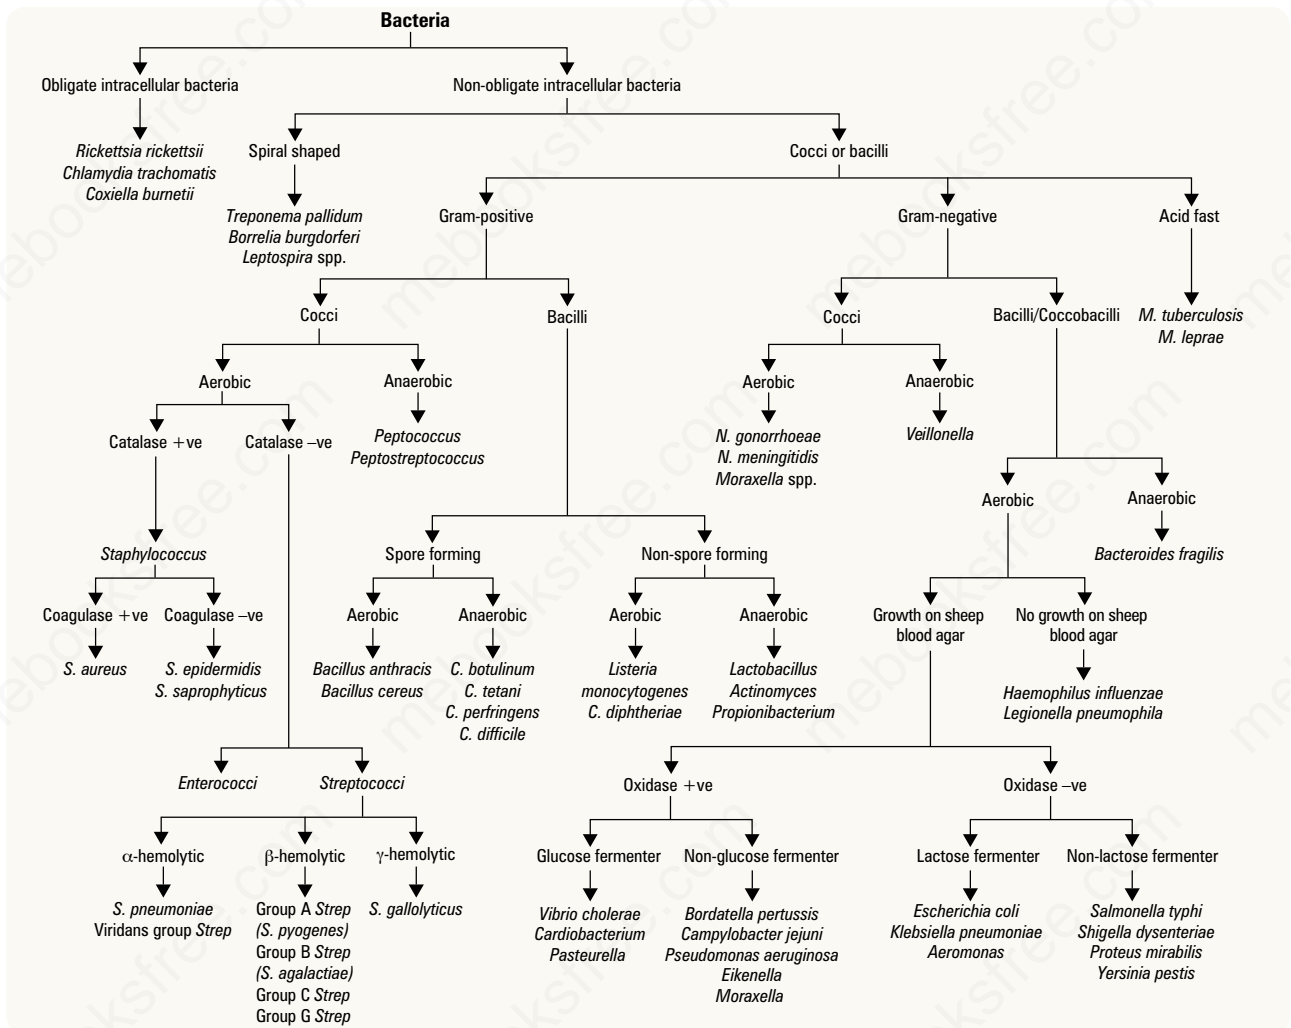

Figure 2. Laboratory identification of bacterial species

Virology

Viral Basics

- viruses are infectious particles consisting of RNA or DNA covered by a protein coat
 - infect cells and use host metabolic machinery to replicate
 - nucleic acid can be double stranded (ds) or single stranded (ss)
 - can be enveloped or naked
- virions are mature virus particles that can be released into the extracellular environment
- host susceptibility is governed by the host cell and virus surface proteins (viral tropism) and cellular immunity

Viral Disease Patterns

- acute infections (e.g. adenovirus)
 - host cells are lysed in the process of virion release
 - some produce acute infections with late sequelae (e.g. measles virus induced subacute sclerosing panencephalitis)
- chronic infections (>6 mo): (e.g. HBV, HIV)
 - host cell machinery is used to produce and chronically release virions
- latent infections
 - viral genome remains latent in host cell nucleus
 - can reactivate (e.g. HSV, VZV)

Table 3. Common Viruses

Nucleic Acid	Enveloped	Virus Family	Major Viruses	Medical Importance
dsDNA	N	<i>Adenoviridae</i>	Adenovirus	URTI Conjunctivitis Gastroenteritis
	N	<i>Papillomaviridae</i>	HPV1,4 HPV6,11 HPV16,18, etc.	Plantar warts Genital warts Cervical/anal dysplasia and cancer
	Y	<i>Herpesviridae</i>	HHV1=HSV1 HHV2=HSV2 HHV3=VZV HHV4=EBV HHV5=CMV HHV6* HHV8=KSHV	Oral, ocular, and genital herpes; encephalitis Genital, oral, and ocular herpes; encephalitis Chicken pox, shingles Mononucleosis, viral hepatitis Retinitis, pneumonitis, hepatitis, encephalitis Roseola Kaposi's sarcoma, multicentric Castleman's disease, body cavity lymphoma
	N	<i>Polyomaviridae</i>	JC virus	Progressive multifocal leukoencephalopathy
	Y	<i>Hepadnaviridae</i>	Hepatitis B	Hepatitis
	Y	<i>Poxviridae</i>	Variola	Smallpox
ssDNA	N	<i>Parvoviridae</i>	Parvovirus B19	Erythema infectiosum (Fifth disease)
(+) ssRNA	N	<i>Caliciviridae</i>	Norwalk Hepatitis E	Gastroenteritis Acute hepatitis
	N	<i>Picornaviridae</i>	Poliovirus Echovirus Rhinovirus Coxsackie virus Hepatitis A	Poliomyelitis URTIs, viral meningitis URTIs Hand-foot-and-mouth, viral meningitis, myocarditis Acute hepatitis
	Y	<i>Coronaviridae</i>	Coronavirus	URTIs, SARS, MERS
	Y	<i>Flaviviridae</i>	Yellow fever Dengue fever Hepatitis C West Nile Zika	Yellow fever Dengue fever Hepatitis Encephalitis, flaccid paralysis Zika virus disease
	Y	<i>Togaviridae</i>	Rubella Chikungunya	Rubella (German measles) Chikungunya
	(+) ssRNA-RT	Y	<i>Retroviridae</i>	HIV HTLV-1
(+) ssRNA	Y	<i>Arenaviridae</i>	Lassa	Lassa fever
	Y	<i>Filoviridae</i>	Ebola, Marburg	Hemorrhagic fever
	Y	<i>Orthomyxoviridae</i>	Influenza A, B, C	Influenza
	Y	<i>Paramyxoviridae</i>	Measles Mumps Parainfluenza RSV	Measles Mumps URTIs, croup, bronchiolitis Bronchiolitis, pneumonia
	Y	<i>Rhabdoviridae</i>	Rabies	Rabies
dsRNA	N	<i>Reoviridae</i>	Rotavirus	Gastroenteritis

Note: ___viridae = family, ___virus = genus, # = species (e.g. Retroviridae HIV-2)

*Roseolovirus, Herpes lymphotropic virus

Herpesviridae
Adenoviridae
Papillomaviridae
Parvoviridae
Polyomaviridae
Poxviridae

Mycology

Fungal Basics

- fungi are eukaryotic organisms, they can have the following morphologies
- 1. yeast (unicellular)
- 2. moulds, also known as filamentous fungi (multicellular with hyphae)
- 3. dimorphic fungi (found as mould at room temperature but grow as yeast-like forms at body temperature)

Table 4. Membrane and Cell Wall Compositions

	Membrane Sterol	Cell Wall
Bacteria	–	Peptidoglycan
Human Cell	Cholesterol	–
Fungi	Ergosterol	Chitin (complex glycopolysaccharide)

Mechanisms of Fungal Disease

- primary fungal infection by
 - overgrowth of normal flora (e.g. *Candida* species)
 - inhalation of fungal spores
 - traumatic inoculation into skin
- toxins produced by fungi (e.g. ingestion aflatoxins)
- allergic reactions to fungi (e.g. bronchopulmonary aspergillosis)

Parasitology

Parasite Basics

- **parasite:** an organism that lives in or on another organism (host) and damages the host in the process
- parasites with complex life cycles require more than one host to reproduce
 - reservoir host: maintains a parasite and may be the source for human infection
 - intermediate host: maintains the asexual stage of a parasite or allows development of the parasite to proceed through the larval stages
 - definitive host: allows the parasite to develop to the adult stage where reproduction occurs
- 2 major groups of parasites: protozoa and helminths
- see Tables 26 and 27 for examples of clinically important parasites

Table 5. Differences Between Protozoa and Helminths

Protozoa	Helminths
Unicellular	Multicellular
Motile trophozoite inactive cyst	Adult egg larva
Multiplication	No multiplication in human host
Eosinophilia unusual	Eosinophilia (proportional to extent of tissue invasion)*
Indefinite life span	Definite life span

*Adult *Ascaris* (roundworm) does not cause eosinophilia; migratory larval phases of *Ascaris*, however, cause high-grade eosinophilia

Characteristics of Parasitic Disease

- symptoms are usually proportional to parasite burden
- tissue damage is due to the parasite and host immune response
- chronic infections may occur with or without overt disease
- immunocompromised hosts are more susceptible to manifestations of infection, reactivation of latent infections, and more severe disease
- eosinophilia may suggest a parasitic infection

Mechanisms of Parasitic Disease

1. mechanical obstruction (e.g. ascariasis, clonorchiasis)
2. competition with host for resources (e.g. anemia in hookworm disease, vitamin B12 deficiency in diphyllobothriasis)
3. cytotoxicity leading to abscesses and ulcers (e.g. amoebiasis, leishmaniasis)
4. inflammatory
 - acute hypersensitivity (e.g. pneumonitis in Loeffler's syndrome)
 - delayed hypersensitivity (e.g. egg granulomas in schistosomiasis)
 - cytokine-mediated (systemic illness of malaria, disseminated strongyloidiasis)
5. immune-mediated injury
 - autoimmune (e.g. myocarditis of Chagas disease, tissue destruction of mucocutaneous leishmaniasis)
 - immune complex (e.g. nephritis of malaria, schistosomiasis)

Figure 4. Common fungus morphology

Figure 5. Classification of protozoa based on movement

Parasite sampling may need to be repeated on a number of occasions before infection can be ruled out

Transmission of Infectious Diseases

Table 6. Mechanism of Transmission

Mechanism	Mode of Transmission	Examples	Preventative Measure
Contact	Direct physical contact, or indirect contact with a fomite	Skin-to-skin (MRSA) Sexual (<i>N. gonorrhoeae</i> , <i>C. trachomatis</i> , HSV, HIV) Blood-borne (HIV, HBV, HCV)	For patients in health care facilities: Contact precautions Barrier precautions Safe needlestick/sharp practices
Droplet/ Contact	Respiratory droplets (>5 µm) can be projected short distances (≤2 m) and deposit on mucosal surfaces of the recipient (e.g. by coughing, sneezing, or talking); transmission can also occur by direct physical contact of respiratory fluids or indirect contact with a fomite contaminated with respiratory fluids	Influenza, mumps <i>N. meningitidis</i> , <i>Bordetella pertussis</i>	For patients in health care facilities: Contact/droplet precautions
Airborne	Airborne droplet nuclei (<5 µm) remain infectious over time and distance	<i>M. tuberculosis</i> , VZV, measles	For patients in health care facilities: Airborne precautions
Food/ Waterborne	Ingestion of contaminated food or water	<i>V. cholerae</i> , <i>Salmonella</i> , HAV, HEV	Prophylactic vaccinations where available Ensure clean food/water supply For patients in health care facilities: Contact precautions used for admitted patients with fecal incontinence when stool is unable to be contained in diapers
Zoonotic	Disease transmission from animals to humans either directly or via an insect vector	Animals (rabies, Q fever) Arthropods (malaria, Lyme disease)	Prophylactic medications, vaccinations Protective clothing, insect repellent, mosquito nets, tick inspection
Vertical	Spread of disease from parent to offspring	Congenital syndromes (TORCH infections) Perinatal (HIV, HBV, GBS)	Prenatal screening Prophylactic treatment

Nosocomial Infections

- **definition:** infections acquired >48 h after admission to a healthcare facility OR within 30 d from discharge
- **risk factors:** prolonged hospital stay, antibiotic use, surgery, hemodialysis, intensive care, colonization with a resistant organism, immunodeficiency
- patients with nosocomial infections have higher mortality, longer hospital stays, and higher healthcare costs
- hand hygiene is an essential precaution

Table 7. Common Nosocomial Infectious Agents

Bacteria	Characteristics	Manifestation	Investigations	Management
Methicillin-Resistant <i>S. aureus</i> (MRSA)	Gram-positive cocci	Skin and soft tissue infection Bacteremia Pneumonia Endocarditis Osteomyelitis	Admission screening culture from nares and peri-anal region identifies colonization Culture of infection site CXR	Contact precautions For infection: vancomycin or daptomycin or linezolid To decolonize: 2% chlorhexidine wash OD (+ rifampin + (doxycycline or TMP/SMX) + mupirocin cream bid to nares) x 7 d
Vancomycin-Resistant <i>Enterococcus</i> (VRE)	Majority are <i>E. faecium</i> Resistant if minimum inhibitory concentration of vancomycin is ≥32 µg/mL	Rarely causes disease in healthy people UTI Bacteremia Endocarditis Meningitis	Rectal or perirectal swab OR stool culture for colonization Culture of infected site	Contact precautions* Ampicillin if susceptible Otherwise, linezolid, tigecycline, or daptomycin depending on site of infection No effective decolonization methods identified
<i>Clostridium difficile</i> (<i>C. difficile</i>)	Releases exotoxins A and B Hypervirulent strain (NAP1/B1/027) has been responsible for increase in incidence and severity	Fever, nausea, abdominal pain Watery diarrhea ± occult blood Pseudomembranous colitis Severe: toxic megacolon Risk of bowel perforation Associated with antibiotic use Leukocytosis	Stool PCR for toxin A and B genes Stool immunoassay for toxins A and B (less sensitive than PCR) AXR (may see colonic dilatation) Sigmoidoscopy for pseudomembranes; avoid if known colonic dilatation	Contact precautions Stop culprit antibiotic therapy (primarily fluoroquinolones and cephalosporins) Supportive therapy (IV fluids) Mild-moderate disease: metronidazole PO x 10-14 d Severe disease: vancomycin PO x 10-14 d Toxic megacolon: metronidazole IV + vancomycin PO (as above) and general surgery consult
Extended Spectrum β-lactam Producers (ESBL producing <i>E. coli</i>, <i>K. pneumoniae</i>)	Resistant to most β-lactam antibiotics except carbapenams e.g. penicillins, aztreonam**, and cephalosporins	UTI Pulmonary infection Bacteremia Liver abscess in susceptible patients Meningitis	Blood, sputum, urine, or aspirated body fluid culture Imaging at infection site (CXR, CT, U/S)	Carbapenems or non-β-lactam antibiotics can be used for empiric therapy

*the use of contact precautions for VRE varies depending on institutional policies.

**Not available in Canada

Respiratory Infections

Pneumonia

• see [Pediatrics](#), P80

Definition

- infection of the lung parenchyma

Etiology and Risk Factors

- impaired lung defenses
 - poor cough/gag reflex (e.g. illness, drug-induced)
 - impaired mucociliary transport (e.g. smoking, cystic fibrosis)
 - immunosuppression (e.g. steroids, chemotherapy, AIDS/HIV, DM, transplant, cancer)
- increased risk of aspiration
 - impaired swallowing mechanism (e.g. impaired consciousness, neurologic illness causing dysphagia, mechanical obstruction)
- no organism identified in 75% of hospitalized cases, and >90% of ambulatory cases

Table 8. Common Organisms in Pneumonia

Community-Acquired	Nosocomial	Aspiration	Immunocompromised Patients	Alcoholic
Typical Bacteria <i>Streptococcus pneumoniae</i> <i>Moraxella catarrhalis</i> <i>Haemophilus influenzae</i> <i>Staphylococcus aureus</i>	Enteric GNB (e.g. <i>E. coli</i>) <i>Pseudomonas aeruginosa</i> <i>S. aureus</i> (including MRSA)	Oral anaerobes (e.g. <i>Bacteroides</i>) Enteric GNB (e.g. <i>E. coli</i>) <i>S. aureus</i>	<i>Pneumocystis jiroveci</i> Fungi (e.g. <i>Cryptococcus</i>) <i>Nocardia</i> CMV HSV TB	<i>Klebsiella</i> Enteric GNB <i>S. aureus</i> Oral anaerobes (aspiration) TB
Atypical Bacteria <i>Mycoplasma pneumoniae</i> <i>Chlamydia pneumoniae</i> <i>Legionella pneumophila</i>				
Viral Influenza virus Adenovirus				

*See [Pediatrics](#), P81, Table for Common Causes and Treatment of Pneumonia at Different Ages

Clinical Presentation

- cough (± sputum), fever, pleuritic chest pain, dyspnea, tachypnea, tachycardia
- elderly often present atypically; altered LOC is sometimes the only sign
- evidence of consolidation (dullness to percussion, bronchial breath sounds, crackles)
- features of parapneumonic effusion (decreased air entry, dullness to percussion)
- complications: ARDS, lung abscess, parapneumonic effusion/empyema, pleuritis ± hemorrhage

Investigations

- pulse oximetry to assess severity of respiratory distress
- CBC and differential, electrolytes, urea, Cr, ABG (if respiratory distress), troponin/CK, LFTs, urinalysis
- sputum Gram stain/C&S, blood C&S, ± serology/viral detection, ± pleural fluid C&S (if effusion >5 cm or respiratory distress)
- CXR±CT chest shows distribution (lobar consolidation or interstitial pattern), extent of infiltrate ± cavitation
- bronchoscopy ± washings for:
 - (1) severely ill patients refractory to treatment and (2) immunocompromised patients

Treatment

- ABC, O₂, IV fluids, consider salbutamol (nebulized or MDI)
- determine prognosis and need for hospitalization and antibiotics

Criteria for Hospitalization

Table 9. CURB 65 Score – Pneumonia Clinical Prediction Tool

Component*	Measurement(s)	Points	Total Score	Mortality	Disposition
Confusion	Altered mental status	1	0-1	<5%	Can treat as outpatient
Urea/BUN	Urea >7 mmol/L or BUN >20 mg/dL	1	2-3	5-15%	Consider hospitalization
Respiratory Rate	>30 breaths/min	1	4-5	15-30%	Consider ICU
Blood Pressure	Systolic <90 or diastolic <60 mmHg	1			
Age	65 or older	1			

* A CRB-65 score may be applied in the community as its criteria depend on clinical assessment alone

When *Klebsiella* causes pneumonia; see red currant jelly sputum

3 As of *Klebsiella*
Aspiration pneumonia
Alcoholics and diabetics
Abscess in lungs

Aspiration pneumonias more commonly manifest as infiltrates in the right middle or lower lobes due to the larger calibre and more vertical orientation of the right bronchus

Does This Patient Have Ventilator-Associated Pneumonia?
JAMA 2007;297:1583-1593
Study: Systematic review of articles describing the precision and accuracy of clinical, radiographic, and laboratory data to diagnose bacterial ventilator-associated pneumonia, which is the most common and fatal nosocomial complication of intensive care.
Results: The presence of a new infiltrate on radiography with 2 or more of purulent sputum, fever, or increased white blood cell count increases the likelihood of ventilator-associated pneumonia (LR 2.8, 95% CI 0.97-7.9). Fewer than 50% neutrophils on the cell count of lower pulmonary secretions make ventilator-associated pneumonia unlikely (LR 0.05-0.10).
Conclusions: Routine bedside evaluation with radiographic information provides suggestive, but not definitive, evidence of ventilator-associated pneumonia. Clinicians need to consider additional tests to provide further evidence for ventilator-associated pneumonia.

Table 10. IDSA/ATS Community Acquired Pneumonia Treatment Guidelines 2007

Setting	Circumstances	Treatment
Outpatient	Previously well No antibiotic use in last 3 mo	Macrolide ¹ OR Doxycycline
	Comorbidities ² Antibiotic use in last 3 mo (use different class)	Respiratory fluoroquinolone ³ OR β -lactam ⁴ + Macrolide ¹
Inpatient	Ward	Respiratory fluoroquinolone ³
	ICU	β -lactam ⁴ + (Macrolide ¹ OR Respiratory fluoroquinolone ³)

1. **Macrolide:** azithromycin, clarithromycin, erythromycin

2. **Comorbidities:** chronic heart, lung, liver, or renal disease, DM, alcoholism, malignancy, asplenia, immunocompromised

3. **Respiratory fluoroquinolone:** moxifloxacin, gemifloxacin, levofloxacin

4. **β -lactam:** cefotaxime, ceftriaxone, ampicillin-sulbactam

IDSA: Infectious Diseases Society of America

ATS: American Thoracics Society

Table 11. IDSA/ATS Hospital-Acquired (HAP) and Ventilator-Associated (VAP) Pneumonia Clinical Practice Guidelines 2016

Setting	Treatment
Clinically suspected HAP (non-VAP) with no increase in likelihood of MRSA and not at high risk of mortality	One of: piperacillin-tazobactam OR cefepime OR levofloxacin OR imipenem or meropenem
Clinically suspected HAP (non-VAP) with increasing likelihood of MRSA and not at high risk of mortality	One of: piperacillin-tazobactam OR cefepime or ceftazidime OR levofloxacin or ciprofloxacin OR imipenem or meropenem OR aztreonam* PLUS one of: vancomycin or linezolid for MRSA coverage
Clinically suspected HAP (non-VAP) with high risk of mortality or recipient of IV Abx in last 90 d	Two of the following (avoid 2 β-lactams): piperacillin-tazobactam OR cefepime or ceftazidime OR levofloxacin or ciprofloxacin OR imipenem or meropenem OR aztreonam* OR amikacin or gentamicin or tobramycin PLUS either MRSA or MSSA coverage: MRSA: vancomycin or linezolid OR MSSA: piperacillin-tazobactam, cefepime, levofloxacin, imipenem, meropenem
Clinically suspected VAP in units where empiric MRSA coverage and double antipseudomonal/ Gram-negative coverage are appropriate	One of: β -lactam/ β -lactamase inhibitor (piperacillin/tazobactam) OR antipseudomonal cephalosporin (cefepime or ceftazidime) OR antipseudomonal carbapenem (imipenem or meropenem) OR monobactam (aztreonam*) PLUS one of: antipseudomonal fluoroquinolone (ciprofloxacin or levofloxacin) OR aminoglycoside (amikacin, gentamicin, or tobramycin) OR polymyxins (colistin or polymyxin B) PLUS one of: vancomycin or linezolid for MRSA coverage

*Not available in Canada

Risk factors for mortality include need for ventilatory support due to pneumonia and septic shock need for ventilatory support due to pneumonia and septic shock

Risk factors for MDR VAP: prior IV Abx use within 90 days, septic shock at time of VAP, ARDS preceding VAP, 5+ days of hospitalization prior to VAP onset, acute renal replacement therapy prior to VAP onset

Risk factors for MDR HAP, MRSA VAP/HAP or MDR pseudomonas VAP/HAP: Prior IV Abx use within 90 days

Note: Indications for MRSA coverage includes IV Abx treatment during the prior 90 d and treatment in a unit where prevalence of MRSA of *S. aureus* isolates is not known or is >20%

Note: These guidelines may be less applicable in Canada given lower rates of antibiotic resistance among common nosocomial pathogens

Prevention

- Public Health Agency of Canada recommends the following
 - vaccine for influenza A and B annually for all ages ≥ 6 mo
 - pneumococcal polysaccharide vaccine (Pneumovax[®]) for all adults >65 yr and in younger patients 24 mo of age and older at high risk for invasive pneumococcal disease (e.g. functional or anatomic asplenia, congenital or acquired immunodeficiency)
 - pneumococcal conjugate vaccine (Prevnar-13[®]) for all children <5 yr, and for children and adolescents at high risk for invasive pneumococcal disease who are 5-17 yr and who have not previously received Prevnar-13[®] (CDC recommends giving Prevnar-13[®] to all adults at high risk for invasive pneumococcal disease)

Lobar Pneumonia

Bronchopneumonia

Interstitial Pneumonia

©Stuart Jantzen 2012

Figure 6. Lobar, broncho, and interstitial pneumonia

Does This Adult Patient Have Pneumonia?

From The Rational Clinical Examination

JAMA 2009; <http://www.jamaevidence.com/content/3485708>

Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult community acquired pneumonia.

Results: The presence of fever or immunosuppression had a positive likelihood ratio (+LR) of 2, while a history of dementia had a +LR of 3; however, these traits are not confirmatory. The presence of an abnormality in any vital sign, including tachycardia, tachypnea, or fever had a +LR ranging from 2-4, which was not significantly affected by different cut-points. The absence of vital sign abnormality had a -LR ranging from 0.5-0.8. The combination of respiratory rate <30/min, heart rate <100/min, and temperature <37.8°C had a -LR of 0.18. Findings on chest exam raised the likelihood of diagnosis, but were uncommonly seen in studies. For example, presence of asymmetric respirations essentially confirmed the diagnosis, but was only present in 4% of patients. In patients with a clinical diagnosis, but normal radiograph, only ~10% will develop radiographic findings in 72 h.

Conclusions: Evidence suggests no single item on clinical history or physical exam is sufficient to rule in or out pneumonia without chest x-ray. Vital sign abnormalities were correlated with a diagnosis of pneumonia. Findings on chest exam significantly raised the likelihood of pneumonia, but were uncommonly seen in studies.

Influenza

Definitions and Etiology

- influenza viruses A and B
- influenza A further divided into subtypes based on envelope glycoproteins
 - hemagglutinin (H) and neuraminidase (N)
- seasonal (epidemic) influenza
 - main circulating influenza viruses: influenza A (H1N1), influenza A (H3N2) and influenza B
 - associated with antigenic drift (gradual, minor changes due to random point mutations)
 - may create a new viral subtype resulting in a seasonal epidemic (disease prevalence is greater than expected)
 - outbreaks occur mainly during winter months (late December to early March)
- pandemic influenza
 - associated with antigenic shift: abrupt, major changes due to mixing of two different viral strains from different hosts
 - may create a new viral strain resulting in a pandemic outbreak (worldwide)
 - antigenic shift occurs only in type A
- transmission: droplet, possibly airborne

Table 12. Difference Between Influenza Strains

	Influenza A	Influenza B
Host(s)	Humans, birds, mammals	Humans only
Antigenic drift	Yes, new strains	Yes, new strains
Antigenic shift	Yes, new subtypes	No
Epidemics	Yes	Yes
Pandemics	Yes	No

Clinical Presentation

- incubation period 1-4 d and symptoms typically resolve in 7-10 days
- acute onset of systemic (fever, chills, myalgias, arthralgias, H/A, fatigue) and respiratory symptoms (cough, dyspnea, pharyngitis)
- complications: respiratory (viral pneumonia, secondary bacterial pneumonia, otitis media, sinusitis), muscular (rhabdomyolysis, myositis), neurologic (encephalitis, meningitis, transverse myelitis, Guillain-Barré syndrome)
- severe disease more likely in the elderly, children, pregnant women, patients with immunocompromise, asthma, COPD, CVD, diabetes and obesity

Investigations

- diagnosis is primarily clinical based on symptoms during the influenza season
- nasopharyngeal swabs for RT-PCR (gold standard), or rapid antigen detection (DFA, direct fluorescent antigen) detection
- serology: rarely used for clinical management

Treatment and Prevention

- primarily supportive unless severe infection or high-risk of complications
- neuraminidase inhibitors: zanamivir (Relenza®) and oseltamivir (Tamiflu®) for treatment and prophylaxis against types A and B
 - decreases duration (by ~1 d) and severity of symptoms if given within 48 h of onset
 - treatment beyond 48 h time window may be warranted in immunosuppressed and critically ill patients
- vaccine for influenza A and B viruses is recommended annually for all ages ≥ 6 mo
 - vaccine is reformulated each year to reflect circulating influenza A and B strains

Beware! Do Not Confuse *H. influenzae* with Influenza Virus

H. influenzae: a bacterium (Types A, B, C, D, E, F, refer to capsule)

Influenza: a virus (Types A and B refer to strain)

Vaccines for Preventing Influenza in Healthy Adults

Cochrane DB Syst Rev 2014;CD001269

Study: Meta-analysis of 90 RCTs and quasi-RCTs evaluating influenza vaccines compared to placebo in healthy individuals aged 16-65 yr.

Results: The preventative effect of inactivated influenza vaccine on healthy adults is small: 40 people would need a vaccination to avoid one influenza-like illness and 71 people would need a vaccination to prevent one case of influenza. 15.6% of unvaccinated versus 9.9% of vaccinated people developed influenza-like symptoms: of these participants, only 2.4% and 1.1%, respectively, developed laboratory-confirmed influenza.

Vaccination had a modest effect on working days lost, but no effects on hospitalization or complications. The effectiveness of live aerosol vaccinations on healthy adults is similar to that of inactivated influenza vaccines: 46 people would need a vaccination to avoid one influenza-like illness.

Conclusions: Influenza vaccines have a very modest effect in reducing influenza-like illness and working days lost in the general population.

Skin and Soft Tissue Infections

Cellulitis

Definition

- acute infection of the skin principally involving the dermis and subcutaneous tissue

Etiology

- common causative agents: *S. aureus*, β -hemolytic streptococci
- immunocompromised patients or water exposure: may also include GN rods and fungi
- risk factors
 - trauma with direct inoculation, recent surgery
 - peripheral vascular disease, lymphedema DM, cracked skin in feet/toes (tinea pedis)

Clinical Presentation

- pain, edema, erythema with indistinct borders \pm regional lymphadenopathy, systemic symptoms (fevers, chills, malaise)
- can lead to ascending lymphangitis (visible red streaking in skin along lymphatics proximal to area of cellulitis)

Investigations

- CBC and differential, blood C&S if febrile
- skin swab ONLY if open wound with pus

Treatment

- antibiotics: cephalexin (broader coverage if risk factors for GN rods)
- if extensive erythema or systemic symptoms, consider cefazolin IV
- if MRSA is suspected, alternative therapy should be prescribed (see *A Simplified Look at Antibiotics, ID47*)
- limb rest and elevation may help reduce swelling

Necrotizing Fasciitis

Definition

- life- and limb-threatening infection of the deep fascia characterized by rapid spread

Etiology

- two main forms
 - Type I: polymicrobial infection – aerobes and anaerobes (e.g. *S. aureus*, *Bacteroides*, *Enterobacteriaceae*)
 - Type II: monomicrobial infection with GAS, and less commonly *S. aureus*

Clinical Presentation

- pain out of proportion to clinical findings and beyond border of erythema
- edema, \pm crepitus (subcutaneous gas from anaerobes), \pm fever
- infection spreads rapidly
- patients may rapidly become very sick (tachycardia, hypotension, lightheadedness)
- late findings
 - skin turns dusky blue and black (secondary to thrombosis and necrosis)
 - induration, formation of hemorrhagic bullae

Investigations

- clinical/surgical diagnosis – do NOT wait for results of investigations before beginning treatment
- blood and tissue C&S
- serum CK (elevated CK usually means myonecrosis – a late sign)
- plain film x-ray (soft tissue gas may be visualized)
- surgical exploration for debridement of infected tissue

Treatment

- resuscitation with IV fluids
- emergency surgical debridement to confirm diagnosis and remove necrotic tissue (may require amputation)
- IV antibiotics
 - unknown organism: meropenem or piperacillin/tazobactam + clindamycin IV \pm vancomycin if MRSA is considered
 - Type I (polymicrobial): piperacillin/tazobactam + clindamycin IV
 - Type II (monomicrobial): cefazolin (or cloxacillin) + clindamycin IV; with confirmed GAS infection, penicillin G + clindamycin IV
 - with Type II, evaluate for streptococcal toxic shock syndrome and the need for IVIg

Gastrointestinal Infections

Acute Diarrhea

- see [Gastroenterology, G15](#) and [Pediatrics, P34](#)

Epidemiology

- one of the top five leading causes of death worldwide, according to the World Health Organization
- significant morbidity in developed countries (over 900,000 hospitalizations in the United States each year)

Definition

- passage of ≥ 3 loose or liquid stools/d OR >200 g stool/d for >2 d but ≤ 14 d

Approach to Acute Diarrhea

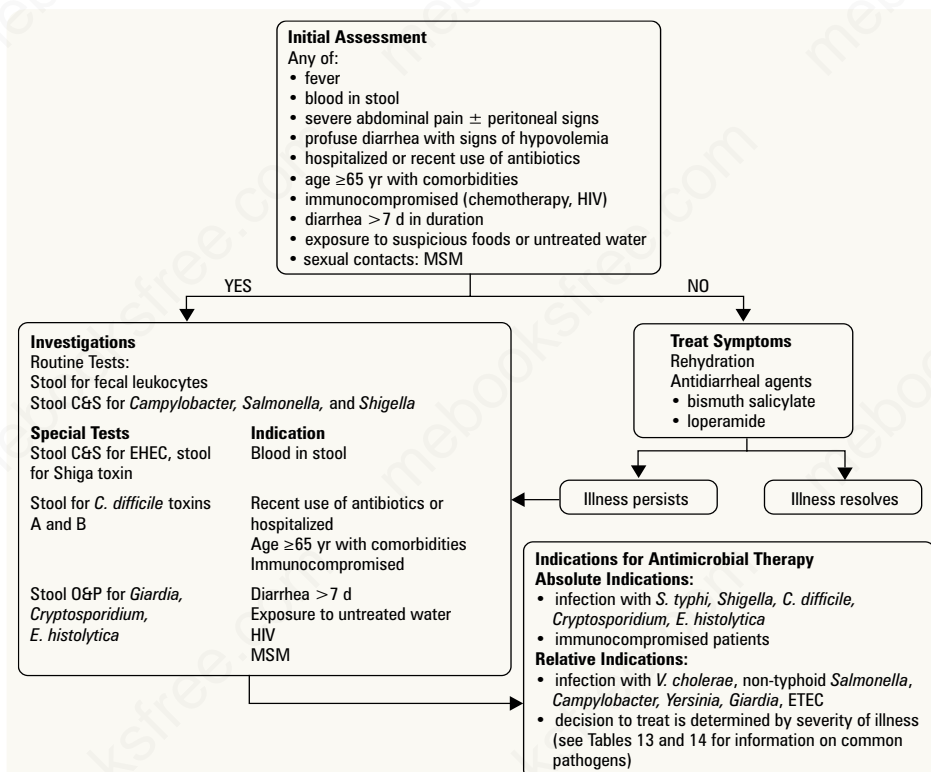

- rationale
 - the vast majority of acute diarrhea is caused by infection
 - in most cases, acute diarrheal illness is viral and/or self-limited, and lasts <3 d
 - investigations are costly and are necessary only in certain circumstances
- therefore, the evaluation of acute diarrhea involves
 - identifying characteristics of the illness or patient that warrant further investigation
 - assessing volume status to determine appropriate method of rehydration

Physical Exam

- volume status: appearance, level of alertness, pulse, BP, orthostatic vitals, JVP, mucous membranes, skin turgor, capillary refill
- abdominal exam: pain, guarding, peritoneal signs

Treatment

- rehydration is mainstay of treatment
 - oral rehydration therapy
 - IV rehydration if oral intake insufficient to replace fluid loss
- antidiarrheal agents reduce duration of diarrhea: loperamide, bismuth salicylate
 - delays excretion of causative pathogens
 - contraindications: diarrhea with fever, bloody stool or diarrhea caused by *C. difficile*
- antibiotic therapy is rarely indicated because:
 - most acute diarrheal illness is viral and self-limited
 - antibiotics can eradicate normal gut flora, predisposing patient to *C. difficile* infection
 - antibiotics prolong the shedding of *Salmonella* and other causes of bacterial diarrhea
 - in EHEC infection, antibiotics may increase the risk of HUS

Causes of Acute Bloody Diarrhea

CHES

Campylobacter
Hemorrhagic *E. coli* (e.g. O157:H7)
Entamoeba histolytica
Salmonella
Shigella

Figure 7. Approach to acute diarrhea

Table 13. Bacteria in Infectious Diarrhea

Pathogen	Source or Mode of Transmission	Incubation	Clinical Features				Duration	Antimicrobial Therapy	Notes
			Fever	Bloody Stool	Abdo Pain	N/V			
<i>B. cereus</i> – Type A (emetic)	Rice dishes	1-6 h	–	–	–	+	<12 h	None	Preformed exotoxin
<i>B. cereus</i> – Type B (diarrheal)	Meats, vegetables, dried beans, cereals	8-16 h	–	–	–	–	<24 h	None	Secondary endotoxin
<i>Campylobacter jejuni</i>	Uncooked meat, especially poultry	2-10 d	+	±	+	±	<1 wk	Macrolide or fluoroquinolone if diarrhea >1 wk, bloody diarrhea, or immunocompromised	Most common bacterial cause of diarrhea in Canada Associated with Guillain-Barré syndrome
<i>Clostridium difficile</i>	Can be normally present in colon in small numbers (primary risk factor for disease is exposure to antimicrobials)	Unclear	±	±	±	–	Variable	Stop culprit antibiotic therapy, if possible Supportive therapy (IV fluids) Mild-moderate disease: metronidazole PO x 10-14 d Severe disease: vancomycin PO x 10 - 14 d Toxic Megacolon: metronidazole IV + vancomycin PO (as above) and general surgery consult	Usually follows antibiotic treatment (especially clindamycin, fluoroquinolones, penicillins, cephalosporins) Can develop pseudomembranous colitis
<i>Clostridium perfringens</i>	Contaminated food, especially meat and poultry	8-12 h	±	–	+	–	<24 h	None	<i>Clostridium</i> spores are heat resistant Secondary enterotoxin Enteroinvasive
<i>E. coli</i> (EIEC)	Contaminated food/water	1-3 d	+	±	+	–	7-10 d	None	Relatively uncommon Enterotoxigenic
<i>E. coli</i> (EPEC)	Contaminated food/water	1-3 d	–	–	+	–	3 d	Fluoroquinolone or azithromycin for moderate to severe symptoms	Most common cause of traveller's diarrhea Heat-labile and heat-stable toxins
Enterohemorrhagic <i>E. coli</i> (EHEC/STEC) i.e. O157:H7	Contamination of hamburger, raw milk, drinking, and recreational water	3-8 d	–	+	+	±	5-10 d	None: antibiotics increase risk of HUS	Shiga toxin production Monitor renal function: 10% develop HUS Antidiarrheals increase risk of HUS
<i>Salmonella Typhi</i> <i>S. Paratyphi</i> (i.e. Enteric Fever, Typhoid)	Fecal-oral Contaminated food/water, travel to endemic area	10-14 d	+	±	+	±	<5-7 d	Empiric treatment with ceftriaxone, ciprofloxacin, or azithromycin Fluoroquinolone resistance is increasing	<i>Salmonella typhi</i> : "Rose spot" rash (on anterior thorax, upper abdomen), fever, and abdominal pain precedes diarrhea
Non-typhoidal Salmonellosis <i>S. Typhimurium</i> , <i>S. Enteritidis</i>	Contaminated animal food products, especially eggs, poultry, meat, milk	12-72 h	+	±	+	+	3-7 d	Ciprofloxacin only in severe illness, extremes of age, joint prostheses, valvular heart disease, severe atherosclerosis, cancer, uremia	
<i>Shigella dysenteriae</i>	Fecal-oral Contaminated food/water	1-4 d	+	±	+	+	<1 wk	Fluoroquinolone	Very small inoculum needed for infection Complications include toxic megacolon, HUS Antidiarrheals may increase risk of toxic megacolon
<i>Staphylococcus aureus</i>	Unrefrigerated meat and dairy products (custard, pudding, potato salad, mayo)	2-4 h	–	–	+	+	1-2 d	None	Heat-stable preformed exotoxin
<i>Vibrio cholerae</i>	Contaminated food/water, especially shellfish	1-3 d	–	–	–	–	3-7 d	Tetracycline or quinolones (ciprofloxacin)	Massive watery diarrhea (1-3 L/d) Mortality <1% with treatment
<i>Yersinia</i>	Contaminated food Unpasteurized milk	5 d	+	±	+	±	Up to 3 wk	Fluoroquinolone only for severe illness	Majority of cases in children 1-4 yr Mesenteric adenitis and terminal ileitis can occur without diarrhea, mimicking appendicitis

Table 14. Parasites in Infectious Diarrhea

Pathogen	Source or Mode of Transmission	Incubation	Clinical Features				Duration	Antimicrobial Therapy	Notes
			Fever	Bloody Stool	Abdo Pain	N/V			
<i>Cryptosporidium</i>	Fecal-oral	7 d	±	–	–	+	1-20 d	Paromomycin + nitazoxanide	Immune reconstitution if immunosuppressed
<i>Entamoeba histolytica</i>	Worldwide endemic areas Fecal-oral	2-4 wk	±	+	–	+	Variable	Metronidazole + iodoquinol or paromomycin if symptomatic infection Only iodoquinol or paromomycin for asymptomatic cyst passage	If untreated, potential for liver abscess Sigmoidoscopy shows flat ulcers with yellow exudates
<i>Giardia lamblia</i>	Fecal-oral Contaminated food/ water	1-4 wk	–	–	+	+	Variable	Metronidazole or nitazoxanide Treatment of asymptomatic carriers NOT recommended	Higher risk in: day care children, intake of untreated water ("beaver fever"), MSM, immunodeficiency (decreased IgA) May need duodenal biopsy

Table 15. Viruses in Infectious Diarrhea

Pathogen	Source or Mode of Transmission	Incubation	Clinical Features				Duration	Antimicrobial Therapy	Notes
			Fever	Bloody Stool	Abdo Pain	N/V			
Norovirus	Fecal-oral	24 h	–	–	+	+	24 h	None	Noroviruses includes Norwalk virus
Rotavirus	Fecal-oral	2-4 d	±	–	–	±	3-8 d	None	Can cause severe dehydration Virtually all children are infected by 3 yr of age Oral vaccine given at 2 and 4 mo of age

Traveller's Diarrhea

- see *Acute Diarrhea*, ID11

Epidemiology

- most common illness to affect travellers
- up to 50% of travellers to developing countries affected in first 2 wk and 10-20% after returning home

Etiology

- bacterial (80-90%): *E. coli* most common (ETEC), *Campylobacter*, *Shigella*, *Salmonella*, *Vibrio* (non-cholera); wide regional variation (e.g. *Campylobacter* more common in Southeast Asia)
- viral: norovirus, rotavirus, and astrovirus account for 5-8%
- protozoal (rarely): *Giardia*, *Entamoeba histolytica*, *Cryptosporidium*, and *Cyclospora* for ~10% in long-term travellers
- pathogen-negative traveller's diarrhea common despite exhaustive microbiological workup

Treatment

- rehydration is the mainstay of therapy
 - rehydrate with sealed beverages
 - in severe fluid loss, use oral rehydration solutions (1 package in 1 L boiled or treated water)
- treat symptoms: antidiarrheal agents (e.g. bismuth salicylate, loperamide)
- empiric antibiotics in moderate or severe illness: ciprofloxacin or azithromycin or rifaximin
 - note: there is increasing fluoroquinolone resistance in causative agents, especially in South and Southeast Asia

Prevention

- proper hygiene practices
 - avoid consumption of: foods or beverages from establishments with unhygienic conditions (e.g. street vendors), raw fruits or vegetables without a peel, raw or undercooked meat and seafood
 - avoid untreated water
- bismuth salicylate (Pepto-Bismol®): 60% effective (2 tablets qid according to CDC website)
- CDC Guidelines: antibiotic prophylaxis not recommended
 - increased risk of infection with resistant organisms
 - high risk groups (e.g. immunocompromised) likely to be infected with pathogen not covered by standard antimicrobial agents

Bismuth salicylate (Pepto-Bismol®) can cause patients to have black stools, which may be mistaken for melena

- Dukoral[®]: oral vaccine that offers protection against *V. cholerae* (efficacy ~80%) and ETEC (efficacy ~50-67%)
 - PHAC recommends that it may be considered for the following situations (not recommended for routine use in travellers):
 - ◆ short-term travellers >2 yr old who are high-risk (e.g. chronic illness) for whom there is an increased risk of serious consequences for traveller's diarrhea (e.g. chronic renal failure, CHF, type 1 DM, inflammatory bowel disease)
 - ◆ immunosuppressed
 - ◆ history of repeat traveller's diarrhea
 - ◆ increased risk of acquiring traveller's diarrhea (gastric hypochlorhydria or young children >2 yr),
 - ◆ travellers to cholera endemic countries at increased risk of exposure
- two vaccines against *Salmonella typhi* are available and their effectiveness is estimated to be between 50-70%

Chronic Diarrhea

- see [Gastroenterology, G16](#)

Peptic Ulcer Disease (*H. pylori*)

- see [Gastroenterology, G11](#)

Bone and Joint Infections

Septic Arthritis

Routes of Infection

- hematogenous
 - contiguous osteomyelitis common in children
- direct inoculation via skin/trauma
- iatrogenic (surgery, arthroscopy, arthrocentesis)

Etiology

- gonococcal
 - *N. gonorrhoeae*: previously accounted for 75% of septic arthritis in young sexually active adults
- non-gonococcal
 - *S. aureus*: affects all ages, rapidly destructive, accounts for most non-gonococcal cases of septic arthritis in adults (especially in those with rheumatoid arthritis)
 - *Streptococcus* species (Group A and B)
 - Gram-negatives: affect neonates, elderly, IV drug users, immunocompromised
 - *S. pneumoniae*: affects children
 - *Kingella kingae*: affects children aged <4 yr of age
 - *Haemophilus influenzae* type B (Hib) now rare due to Hib vaccine: consider in unvaccinated children
 - *Salmonella* spp.: characteristic of sickle cell disease
 - coagulase-negative *Staphylococcus* species: prosthetic joints
- if culture negative: partially-treated infection (prior to oral antibiotics), reactive arthritis, rheumatic fever, less common bacterial causes such as *Borrelia* spp. (Lyme disease) or *Tropheryma whippelii* (Whipple's disease), and non-infectious causes

Risk Factors

- gonococcal
 - age (<40 yr), multiple partners, unprotected intercourse, MSM
- non-gonococcal
 - most affected children are previously healthy with no risk factors: occasionally preceding history of minor trauma
 - bacteremia (extra-articular infection with hematogenous seeding, endocarditis)
 - prosthetic joints/recent joint surgery
 - underlying joint disease (rheumatoid arthritis, osteoarthritis)
 - immunocompromise (DM, chronic kidney disease, alcoholism, cirrhosis)
 - loss of skin integrity (cutaneous ulcer, skin infection)
 - age >80 yr

Clinical Presentation of Gonococcal Arthritis

- two forms (although often overlap)
 - bacteremic form
 - systemic symptoms: fever, malaise, chills
 - gonococcal triad: migratory polyarthralgias, tenosynovitis, dermatitis (pustular skin lesions)
 - septic arthritis form
 - local symptoms in involved joint: swelling, warmth, pain, inability to bear weight, marked decrease in range of motion)

Medical Emergency
Septic arthritis is a medical emergency! If untreated, rapid joint destruction will occur

Disseminated Gonococcal Infection Triad

- Migratory arthralgias
- Tenosynovitis next to inflamed joint
- Pustular skin lesions

Clinical Presentation of Non-Gonococcal Arthritis

- acute onset of pain, swelling, warmth, decreased range of motion ± fever and chills; in children, refusal to weight bear
- most often in large weight-bearing joints (knee, hip, ankle) and wrists
- usually monoarticular (polyarticular risk factors: rheumatoid arthritis, endocarditis, GBS)

Investigations

- consider rheumatologic causes for monoarthritis (see [Rheumatology, RH3](#))
- gonococcal: blood C&S, as well as endocervical, urethral, rectal, and oropharyngeal testing
- non-gonococcal: blood C&S
- arthrocentesis (synovial fluid analysis) is mandatory: CBC and differential, Gram stain, C&S, examine for crystals
 - infectious = opaque, increased WBCs (>15,000/mm³): likelihood of infection increases with increasing WBCs, PMNs >90%, culture positive
 - growth of *N. gonorrhoeae* from synovial fluid is successful in <50% of cases
- ± plain x-ray: assess for osteomyelitis, provides baseline to monitor treatment

Treatment

- medical
 - empiric IV antibiotics: specific choice depends on clinical scenario; for most adults, vancomycin + ceftriaxone is reasonable; for fully vaccinated children, cefazolin or cloxacillin IV unless MRSA is a consideration – delay may result in joint destruction
 - Gram stain and cultures guide subsequent treatment
 - gonococcal: ceftriaxone + azithromycin, for concurrent treatment of *C. trachomatis*
 - non-gonococcal: antibiotics against *Streptococcus* spp. (2-3 wk IV f/b PO), *S. aureus* (4 wk IV minimum), or GNB (4 wk)
- surgical drainage if (see [Orthopedics, OR10](#))
 - persistent positive joint cultures on repeat arthrocentesis
 - hip joint involvement
 - prosthetic joint
- daily joint aspirations until culture sterile; no need to give intra-articular antibiotics
- physiotherapy

Prognosis

- gonococcal: responds well after 24-48 h of initiating antibiotics (usually complete recovery)
- non-gonococcal: in children, generally good outcome if treated promptly; in adults, up to 50% morbidity (decreased joint function/mobility)

Intra-articular steroids are contraindicated until septic arthritis has been excluded

Diabetic Foot Infections

Etiology

- neuropathy, peripheral vascular disease, and hyperglycemia contribute to foot ulcers that heal poorly, and are predisposed to infection
- organisms in mild infection: *S. aureus*, *Streptococcus* spp.
- organisms in moderate/severe infection: polymicrobial with aerobes (*S. aureus*, *Streptococcus*, *Enterococcus*, GNB) and anaerobes (*Peptostreptococcus*, *Bacteroides*, *Clostridium*)

Clinical Presentation

- not all ulcers are infected
- consider infection if: probe to bone (see below), ulcer present >30 d, recurrent ulcers, trauma, PVD, prior amputation, loss of protective sensation, renal disease, history of walking barefoot
- diagnosis of infected ulcer: ≥2 of the cardinal signs of inflammation (redness, warmth, swelling, pain) OR the presence of pus
- ± crepitus, osteomyelitis, systemic toxicity
- visible bone or probe to bone → osteomyelitis
- infection severity
 - mild = superficial (no bone/joint involvement)
 - moderate = deep (beneath superficial fascia, involving bone/joint) or erythema >2 cm
 - severe = infection in a patient with systemic toxicity (fever, tachypnea, leukocytosis, tachycardia, hypotension)

Investigations

- curettage specimen from ulcer base, aspirate from an abscess or bone biopsy (results from superficial swabs do not represent organisms responsible for deeper infection)
- blood C&S if febrile
- assess for osteomyelitis by x-ray (although not sensitive in early stages) or MRI if high clinical suspicion
 - if initial x-ray normal, repeat 2-4 wk after initiating treatment to increase test sensitivity

Treatment

- evaluate for early surgical debridement ± revascularization or amputation
- eliminate/reduce pressure and provide regular local wound care
- mild: cephalexin or clindamycin

Does this Patient with Diabetes have Osteomyelitis of the Lower Extremity?

JAMA 2008;299:806-813

Study: Systematic literature review. 21 studies.

Population: 1,027 adult patients with DM being investigated for osteomyelitis.

Intervention: Various aspects of history, physical exam, laboratory tests, and diagnostic imaging studies versus bone biopsy.

Primary Outcome: Diagnostic utility.

Results: No studies examined any part of history taking. Temperature, ulcer characteristics (erythema, swelling, purulence), elevated WBC, skin swabs, and soft tissue cultures were not useful. Nuclear imaging has poor specificity for osteomyelitis (62%-88.5%), and MRIs have greater accuracy in detecting osteomyelitis.

Finding	(+) LR	(-) LR
Visualization of bone	9.2	0.70
Ulcer area >2 cm ²	7.2	0.48
Probe-to-bone	6.4	0.39
Clinical judgment	5.5	0.54
ESR >70 mm/h	11	NS*
Plain radiographs	2.3	0.63
MRI	3.8	0.14

*NS = not significant

- moderate: clindamycin + ciprofloxacin or moxifloxacin PO, ceftriaxone or ertapenem IV ± MRSA coverage
- severe: piperacillin/tazobactam or meropenem IV ± vancomycin if MRSA known or suspected
- encourage glycemic control

Osteomyelitis

- see [Orthopedics, OR9](#)

Cardiac Infections

Infective Endocarditis

Definition

- infection of cardiac endothelium, most commonly the valves
- classifications: acute vs. subacute, native valve vs. prosthetic valve, right sided vs. left sided
- leaflet vegetations are made of platelet-fibrin thrombi, WBCs, and bacteria

Risk Factors and Etiology

- predisposing conditions
 - high risk: prosthetic cardiac valve, previous IE, congenital heart disease (unrepaired, repaired within 6 mo, repaired with defects), cardiac transplant with valve disease (surgically constructed systemic-to-pulmonary shunts or conduits)
 - moderate risk: other congenital cardiac defects, acquired valvular dysfunction, hypertrophic cardiomyopathy
 - low/no risk: secundum ASD or surgically repaired ASD < VSD, PDA, MV prolapse, ischemic heart disease, previous CABG
 - opportunity for bacteremia: IVDU, indwelling venous catheter, hemodialysis, poor dentition, DM, HIV
- frequency of valve involvement MV >> AV > TV > PV
 - but in 50% of IVDU-related IE the tricuspid valve is involved

- Etiology of Culture-Negative Endocarditis**
- HACEK (fastidious Gram-negative bacilli)
 - Haemophilus parainfluenzae*
 - Aggregatibacter aphrophilus/Aggregatibacter actinomycetemcomitans*
 - Cardiobacterium hominis*
 - Eikenella corrodens*
 - Kingella kingae*
 - *Coxiella burnetii*
 - *Bartonella species*
 - *Tropheryma whippelii*
 - Fungi
 - *Mycobacteria*

Table 16. Microbial Etiology of Infective Endocarditis Based on Risk Factors

Native Valve	Intravenous Drug Users (IVDU)	Prosthetic Valve (recent surgery < 2 mo)	Prosthetic Valve (remote surgery > 2 mo)
<i>Streptococcus</i> 1 (36%) <i>S. aureus</i> (28%) <i>Enterococcus</i> (11%) <i>S. epidermidis</i> GNB Other ²	<i>S. aureus</i> (68%) <i>Streptococcus</i> (13%) <i>Enterococcus</i> GNB <i>Candida</i> Other ²	<i>S. aureus</i> (36%) <i>S. epidermidis</i> (17%) Other <i>Enterococcus</i> GNB Other ²	<i>Streptococcus</i> (20%) <i>S. aureus</i> (20%) <i>S. epidermidis</i> (20%) <i>Enterococcus</i> (13%) Other ²

Organisms in bold are the most common isolates

1. *Streptococcus* includes mainly viridans group streptococci

2. Other includes less common organisms such as:

- *Streptococcus gallolyticus* (previously known as *S. bovis*; usually associated with underlying GI malignancy, cirrhosis)
- Culture-negative organisms including nutritionally-deficient streptococci, HACEK, *Bartonella*, *Coxiella*, *Chlamydia*, *Legionella*, *Brucella*
- *Candida*

3. IVDU endocarditis pathogens depend on substance used to dilute the drugs (i.e. tap water = *Pseudomonas*, saliva = oral flora, toilet water = GI flora)

Clinical Presentation

- systemic
 - fever (80-90%), chills, weakness, rigors, night sweats, weight loss, anorexia
- cardiac
 - dyspnea, chest pain, clubbing (subacute)
 - regurgitant murmur (new onset or increased intensity)
 - signs of CHF (secondary to acute MR, AR)
- embolic/vascular
 - petechiae over legs, splinter hemorrhages (linear, reddish-brown lesion within nail bed)
 - Janeway lesions (painless, 5 mm, erythematous, hemorrhagic pustular lesions on soles/palms)
 - focal neurological signs (CNS emboli), H/A (mycotic aneurysm)
 - splenomegaly (subacute)
 - microscopic hematuria, flank pain (renal emboli) ± active sediment
- immune complex
 - Osler's nodes (painful, raised, red/brown, 3-15 mm on digits)
 - glomerulonephritis
 - arthritis
 - Roth's spots (retinal hemorrhage with pale centre)

Diagnosis

- Modified Duke Criteria
 - definitive diagnosis if: 2 major, OR 1 major + 3 minor, OR 5 minor
 - possible diagnosis if: 1 major + 1 minor, OR 3 minor

- Clinical Features of Infective Endocarditis**
- FROM JANE**
- Fever
 - Roth's spots
 - Osler's nodes
 - Murmur
 - Janeway lesions
 - Anemia
 - Nail-bed hemorrhages (i.e. splinter hemorrhages)
 - Emboli

Table 17. Modified Duke Criteria

Major Criteria (2)
1. Positive blood cultures for IE <ul style="list-style-type: none"> • Typical microorganisms for IE from 2 separate blood cultures (<i>Streptococcus viridans</i>, HACEK group, <i>Streptococcus gallolyticus</i> (previously known as <i>S. bovis</i>), <i>Staphylococcus aureus</i>, community-acquired enterococci) OR • Persistently positive blood culture, defined as recovery of a microorganism consistent with IE from blood drawn > 12 h apart OR • All of 3 or a majority of 4 or more separate blood cultures, with first and last drawn > 1 h apart OR • Single positive blood culture for <i>Coxiella burnetii</i> or antiphase I IgG antibody titer > 1:800 2. Evidence of endocardial involvement <ul style="list-style-type: none"> • Positive echocardiogram for IE (oscillating intracardiac mass on valve or supporting structures, or in the path of regurgitant jets, or on implanted material in the absence of an alternative anatomic explanation OR abscess OR new partial dehiscence of prosthetic valve) OR • New valvular regurgitation (insufficient if increase or change in preexisting murmur)
Minor Criteria (5)
1. Predisposing condition (abnormal heart valve, IVDU) 2. Fever (38.0°C/100.4°F) 3. Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysms, ICH, conjunctival hemorrhages, Janeway lesions 4. Immunologic phenomena: glomerulonephritis, rheumatoid factor, Osler's nodes, Roth's spots 5. Positive blood culture but not meeting major criteria OR serologic evidence of active infection with organism consistent with IE

Investigations

- serial blood cultures: 3 sets (each containing one aerobic and one anaerobic sample) collected from different sites > 1 h apart
 - persistent bacteremia is the hallmark of endovascular infection (such as IE)
- repeat blood cultures (at least 2 sets) after 48-72 h of appropriate antibiotics to confirm clearance
- blood work: CBC and differential (normochromic, normocytic anemia), ESR (increased), RF (+), BUN/Cr
- urinalysis (proteinuria, hematuria, red cell casts) and urine C&S
- ECG: prolonged PR interval may indicate perivalvular abscess
- echo findings: vegetations, regurgitation, abscess
 - TTE (poor sensitivity) inadequate in 20% (obesity, COPD, chest wall deformities)
 - TEE indicated if TTE is non-diagnostic in patients with at least possible endocarditis or if suspect prosthetic valve endocarditis or complicated endocarditis (e.g. paravalvular abscess/perforation) (~90% sensitivity)

TEE transesophageal echo
 TTE transthoracic echo

Treatment

- medical
 - usually non-urgent and can wait for confirmation of etiology before initiating treatment
 - empiric antibiotic therapy if patient is unstable; administer ONLY after blood cultures have been taken
 - ♦ first line empiric treatment for native valve: vancomycin + gentamicin OR ceftriaxone
 - ♦ first line empiric treatment for prosthetic valve: vancomycin + gentamicin + cefepime + rifampin
 - targeted antibiotic therapy: antibiotic and duration (usually 4-6 wk) adjusted based on valve, organism, and sensitivities
 - monitor for complications of IE (e.g. CHF, conduction block, new emboli) and complications of antibiotics (e.g. interstitial nephritis)
 - prophylaxis only for high risk individuals listed above with dental procedures that may lead to bleeding OR invasive procedure of the respiratory tract that involves incision or biopsy of the respiratory mucosa, such as tonsillectomy and adenoidectomy OR procedures on infected skin, skin structure, or musculoskeletal tissue
 - ♦ dental/respiratory: amoxicillin single dose 30-60 min prior; clindamycin if penicillin-allergic
 - ♦ skin/soft tissue: cephalexin single dose 30-60 min prior; clindamycin if penicillin-allergic (modify based on etiology of skin/soft tissue infection)
- surgical
 - most common indication is refractory CHF
 - other indications include: valve ring abscess, fungal etiology, valve perforation, unstable prosthesis, ≥2 major emboli, antimicrobial failure (persistently positive blood cultures), mycotic aneurysm, *Staphylococci* on a prosthetic valve

Prognosis

- adverse prognostic factors: CHF, prosthetic valve infection, valvular/myocardial abscess, embolization, persistent bacteremia, altered mental status
- mortality: prosthetic valve IE (25-50%), non-IVDU *S. aureus* IE (30-45%), IVDU *S. aureus* or streptococcal IE (10-15%)

CNS Infections

Meningitis

- see [Pediatrics, P54](#)

Definition

- inflammation of the meninges

Etiology

Table 18. Common Organisms in Meningitis

Bacterial			Viral	Fungal	Other
Age 0-4 wk	Age 1-3 mo	Age >3 mo			
GBS	GBS	<i>S. pneumoniae</i>	HSV-1, 2	<i>Cryptococcus</i>	Lyme disease
<i>E. coli</i>	<i>E. coli</i>	<i>N. meningitidis</i>	VZV	<i>Coccidioides</i>	Neurosyphilis
<i>L. monocytogenes</i>	<i>S. pneumoniae</i>	<i>L. monocytogenes</i>	Enteroviruses		TB
<i>Klebsiella</i>	<i>N. meningitidis</i>	(age >50 and comorbidities)	Parechoviruses		
	<i>H. influenzae</i>		West Nile		

Risk Factors

- lack of immunization against *H. influenzae* type b, *S. pneumoniae*, and *N. meningitidis* in children
- most cases of bacterial meningitis are due to hematogenous spread from a mucosal surface (nasopharynx)
- direct extension from a parameningeal focus (otitis media, sinusitis) less common
- penetrating head trauma
- anatomical meningeal defects – CSF leaks
- previous neurosurgical procedures, shunts
- immunodeficiency (corticosteroids, HIV, asplenia, hypogammaglobulinemia, complement deficiency)
- contact with colonized or infected persons

Clinical Presentation

- neonates and children: fever, lethargy, irritability, vomiting, poor feeding
- older children and adults: fever, H/A, neck stiffness, confusion, lethargy, altered level of consciousness, seizures, focal neurological signs, N/V, photophobia, papilledema
- petechial rash in meningococcal meningitis, seen more frequently on trunk or lower extremities

Investigations

- blood work: CBC and differential, electrolytes (for SIADH), blood C&S
 - CSF: opening pressure, cell count + differential, glucose, protein, Gram stain, bacterial C&S
 - AFB, fungal C&S, cryptococcal antigen in immunocompromised patients, subacute illness, suggestive travel history or TB exposure
 - PCR for HSV, VZV, enteroviruses; in infants <6 mo, parechoviruses
 - WNV serology in blood and CSF during summer and early fall if viral cause suspected
- imaging/neurologic studies: CT, MRI, EEG if focal neurological signs present

Table 19. Typical CSF Profiles for Meningitis

CSF Analysis	Bacterial	Viral
Glucose (mmol/L)	Decreased	Normal
Protein (g/L)	Markedly Increased	Increased
WBC	500-10,000/ μ L	10-500/ μ L
Predominant WBC	Neutrophils	Lymphocytes

Treatment

- bacterial meningitis is a medical emergency: do not delay antibiotics for CT or LP
- empiric antibiotic therapy
 - age \leq 28 days: ampicillin + cefotaxime
 - age 29 days-3 mo: cefotaxime + vancomycin
 - age >3 mo: ceftriaxone + vancomycin
 - ♦ add ampicillin IV if risk factors for infection with *L. monocytogenes* present: age >50, alcoholism, immunocompromised
- steroids in acute bacterial meningitis: dexamethasone IV within 20 min prior to or with first dose of antibiotics
 - continue in those patients with proven pneumococcal meningitis
 - not recommended for patients with suspected bacterial meningitis in some resource-limited countries
 - not recommended for neonatal meningitis

Brudzinski's Sign

Passive neck flexion causes involuntary flexion of hips and knees

Kernig's Sign

Resistance to knee extension when hip is flexed to 90°

Jolt Accentuation of H/A

Headache worsens when head turned horizontally at 2-3 rotations; more sensitive than Brudzinski's and Kernig's

CSF Gram Stain Findings

- *S. pneumoniae* – GP diplococci
- *N. meningitidis* – GN diplococci
- *H. influenzae* – Pleiomorphic GN coccobacilli
- *L. monocytogenes* – GP rods

Does this Adult Patient Have Acute Meningitis?

From The Rational Clinical Examination

JAMA 2009; <http://www.jamaevidence.com/content/3482857>

Study: Systematic review of articles assessing the sensitivity and specificity of clinical exam maneuvers for the diagnosis of adult meningitis.

Results: In retrospective studies, sensitivity for headache was 68%, and 52% for nausea and vomiting. Sensitivity for physical exam findings is similarly low (fever: 87%, neck stiffness: 80%, altered mental status: 69%). Sensitivity for the combination of the classic triad of fever, neck stiffness, and altered mental status was 46%. In prospective studies, sensitivity of H/A was 92%, while sensitivity of N/V could not be pooled, and ranged from 32-70%. Brudzinski's and Kernig's signs had a sensitivity of 5% and Kernig's sign only 5-9%. Jolt accentuation had a sensitivity of 97%.

Conclusions: Data were heterogeneous, and lacked standardization of clinical exams. No single item on clinical history or physical exam was sufficient to rule out meningitis, including Kernig's and Brudzinski's signs, or the absence of the classic triad of fever, neck stiffness, and altered mental status meningitis. Jolt accentuation has high sensitivity, but further research is needed. LP may be performed safely without CT head in patients without altered LOC, no recent seizure, no history of CNS disease, not immunocompromised, and <60 yr.

Prevention

- see [Pediatrics, P54](#)
- immunization
 - children: immunization against *H. influenzae* type B (Pentacel®), *S. pneumoniae* (Synflorix®, Prevnar-13®), *N. meningitidis* (Menjugate®, Menactra®, Nimenrix®, Menveo®, Bexsero®)
 - adults: immunization against *N. meningitidis* in selected circumstances (outbreaks, travel, epidemics) and *S. pneumoniae* (Pneumovax®) for high-risk groups
- prophylaxis: close contacts of patients infected with *H. influenzae* type B should be treated with rifampin if they live with an inadequately immunized (<4 yr) or immunocompromised child (<18 yr); ciprofloxacin, rifampin, or ceftriaxone if close or household contact of a patient with *N. meningitidis*; meningococcal vaccines are also recommended for post-exposure prophylaxis for close contacts and in outbreak control

Prognosis

- complications
 - H/A, seizures, cerebral edema, hydrocephalus, SIADH, residual neurological deficit (especially CN VIII), deafness, death
- mortality
 - *S. pneumoniae* 25%; *N. meningitidis* 5-10%; *H. influenzae* 5%
 - worse prognosis if: extremes of age, delays in diagnosis and treatment, stupor or coma, seizures, focal neurological signs, septic shock at presentation

Public Health Agency of Canada Indications for Adult Immunization

Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax®)

- > 65 yr (option to also give pneumococcal conjugate vaccine; if so, to give polysaccharid vaccine 8 wks after conjugate vaccine)

Pneumococcal Polysaccharide Vaccine (i.e. Pneumovax®) and Pneumococcal Conjugate Vaccine

- Chronic cardiovascular/respiratory/hepatic/renal disorders, asplenia, sickle cell, or immunosuppression (polysaccharide vaccine to be given 8 wk after pneumococcal conjugate vaccine)

Meningococcal Quadrivalent Vaccine (Menactra® or Menomune®)

- Healthy young adults
- Asplenia
- Travellers to high-risk areas
- Military recruits or laboratory personnel
- Complement, factor D, or properdin deficiency or acquired terminal complement deficiency through receipt of eculizumab

Multicomponent Meningococcal Serogroup B Vaccine (Bexsero®)

- Asplenia
- Military recruits or laboratory personnel
- Complement, factor D, or properdin deficiency, or acquired terminal complement deficiency through receipt of eculizumab

Meningitis and encephalitis patients can be distinguished based on their cerebral function. Cerebral function is abnormal in encephalitis patients (e.g. altered mental status, motor or sensory deficits, altered behaviour, speech or movement disorders), but may be normal in patients with meningitis. Note however, that there is considerable overlap between the two syndromes ("meningoencephalitis")

Encephalitis

Definition

- inflammation of the brain parenchyma

Etiology

- identified in only 40-70% of cases
 - when cause is identified, the most common etiology is viral: HSV, VZV, EBV, CMV, enteroviruses, parechoviruses, West Nile and other arboviruses, influenza and other respiratory viruses, HIV, mumps, measles, rabies, polio
 - bacteria: *L. monocytogenes*, *mycobacteria*, spirochetes (Lyme, syphilis), *Mycoplasma pneumoniae*
 - parasites: protozoa (e.g. *Toxoplasma*) and helminths (rare)
 - fungi: e.g. *Cryptococcus*
 - post-infectious (e.g. acute disseminated encephalomyelitis [ADEM])
 - auto-antibody mediated encephalitis
 - ♦ anti-N-methyl-D-aspartate (NMDA) receptor encephalitis most common
 - ♦ in adults, most autoantibody-mediated encephalitis cases are associated with malignancy

Pathophysiology

- acute inflammatory disease of the brain due to direct invasion or pathogen-initiated immune response
- viruses may reach the CNS via peripheral nerves (e.g. rabies, HSV)
- herpes simplex encephalitis
 - acute, necrotizing, asymmetrical hemorrhagic process with lymphocytic and plasma cell reaction which usually involves the medial temporal and inferior frontal lobes
 - associated with HSV-1, but can also be caused by HSV-2
- influenza and other respiratory viruses are associated with acute necrotizing encephalopathy (ANE); likely mediated by pathogen-initiated immune response

Clinical Presentation

- constitutional: fever, chills, malaise, N/V
- meningeal involvement (meningoencephalitis): H/A, nuchal rigidity
- parenchymal involvement: seizures, altered mental status, focal neurological signs
- herpes simplex encephalitis
 - acute onset (<1 wk) of focal neurological signs: hemiparesis, ataxia, aphasia, focal or generalized seizures
 - temporal lobe involvement: behavioural disturbance
 - usually rapidly progressive over several days and may result in coma or death
 - common sequelae: memory and behavioural disturbances

Investigations

- CSF: opening pressure, cell count and differential, glucose, protein, Gram stain, bacterial C&S, PCR for HSV, VZV, EBV, enteroviruses/parechoviruses, *M. pneumoniae*, and selectively for other less common etiologies
- serology: may aid diagnosis of certain causes of encephalitis (e.g. EBV, West Nile virus, rabies, *Bartonella henselae*)
- imaging/neurologic studies: CT, MRI, EEG to define anatomical sites affected
- invasive testing: brain tissue biopsy may be required for culture, histological examination, and immunocytochemistry (if diagnosis not clear via non-invasive means)
- findings in herpes simplex encephalitis (must rule out due to high mortality)
 - CT/MRI: medial temporal lobe necrosis
 - EEG: early focal slowing, periodic discharges

Treatment

- general supportive care
- monitor vital signs carefully
- IV acyclovir empirically until HSV encephalitis ruled out

Generalized Tetanus

- see [Pediatrics, P4](#)

**Etiology and Pathophysiology**

- caused by *Clostridium tetani*: motile, spore forming, anaerobic GP bacillus
- found in soil, splinters, rusty nails, GI tract (humans and animals)
- traumatic implantation of spores into tissues with low oxygenation (e.g. puncture wounds, burns, nonsterile surgeries or deliveries)
- upon inoculation, spores transform into *C. tetani* bacilli that produce tetanus toxin
 - toxin travels via retrograde axonal transport to the CNS where it irreversibly binds presynaptic neurons to prevent the release of inhibitory neurotransmitters (e.g. GABA)
 - net effect is the disinhibition of spinal motor reflexes which results in tetany and autonomic hyperactivity

Clinical Presentation

- generalized tetanus
 - initially present with painful spasms of masseters (trismus or “lockjaw”)
 - sustained contraction of skeletal muscle with periodic painful muscle spasms (triggered by sensory stimuli, e.g. loud noises)
 - paralysis descends to involve large muscle groups (neck, abdomen)
 - apnea, respiratory failure, and death secondary to tonic contraction of pharyngeal and respiratory muscles
- autonomic hyperactivity
 - diaphoresis, tachycardia, HTN, fever as illness progresses

Investigations

- primarily a clinical diagnosis, often although not always with a history of a traumatic wound and lack of immunization
- culture wounds, CK may be elevated

Treatment

- stop toxin production
 - wound debridement to clear necrotic tissue and spores
 - antimicrobial therapy: IV metronidazole; IV penicillin G is an effective alternative
- neutralize unbound toxin with tetanus immune globulin (TIG)
- supportive therapy: intubation, spasmolytic medications (benzodiazepines), quiet environment, cooling blanket
- control autonomic dysfunction: α - and β -blockade (e.g. labetalol), magnesium sulfate

Antimicrobial therapy (e.g. metronidazole) may fail to treat *C. tetani* unless adequate wound debridement is performed

Prevention

- infection with *C. tetani* does not produce immunity – vaccinate patients on diagnosis
- tetanus toxoid vaccination (see [Pediatrics, P4](#) and [Emergency Medicine, ER17](#))

**Rabies****Definition**

- acute progressive encephalitis caused by RNA virus (genus *Lyssavirus* of the Rhabdoviridae family)

Etiology and Pathophysiology

- any mammal can transmit the rabies virus
 - most commonly transmitted by raccoon, skunk, bat, fox, cat, and dog; monkeys also a risk in the developing world
- transmission: breaching of skin by teeth or direct contact of infectious tissue (saliva, neural tissue) with skin or mucous membranes
 - almost all cases due to bites
- virus travels via retrograde axonal transport from PNS to CNS
- virus multiplies rapidly in brain, then spreads to other organs, including salivary glands
- development of clinical signs occurs simultaneously with excretion of rabies virus in saliva
 - infected animal can transmit rabies virus as soon as it shows signs of disease

Clinical Presentation

- five stages of disease
 1. incubation period
 - 1-3 mo on average (can range from days to years)

2. prodrome (<1 wk)
 - influenza-like illness: low-grade fever, malaise, anorexia, N/V, H/A, sore throat
 - pain, pruritus, and paresthesia may occur at wound site
 - once prodromal symptoms develop, there is rapid, irreversible progression to death
 - ♦ progression from prodrome to coma and death may occur without an intervening acute neurologic syndrome
3. acute neurologic syndrome: 2 types (<1 wk)
 - a. encephalitic (most common): hyperactivity, fluctuating LOC, hydrophobia, aerophobia, hypersalivation, fever, seizures
 - ♦ painful pharyngeal spasms on encountering gust of air or swallowing water cause aerophobia and hydrophobia, respectively
 - b. paralytic: quadriplegia, loss of anal sphincter tone, fever
4. coma
 - complete flaccid paralysis, respiratory and cardiovascular failure
5. death (within days to weeks of initial symptoms)

Investigations

- purpose of diagnosis by investigations is to limit patient contact with others and to identify others exposed to the infectious source
- ante-mortem: direct immunofluorescence or PCR on multiple specimens: saliva, skin biopsy, serum, CSF
- post-mortem: direct immunofluorescence in nerve tissue, presence of Negri bodies (inclusion bodies in neurons)

Treatment

- post-exposure prophylaxis depends on regional prevalence (contact Public Health) and circumstances surrounding injury
- 3 general principles
 - wound care: clean wound promptly and thoroughly with soap and running water
 - passive immunization: HRIG infiltrated into wound site, with any remaining volume administered IM in anatomical site distant from vaccine administration
 - active immunization: inactivated human diploid cell rabies virus vaccine (series of 4 shots post-exposure if not pre-immunized)
- treatment is supportive once victim manifests signs and symptoms of disease

Prevention

- pre-exposure vaccination
 - recommended for high risk persons: laboratory staff working with rabies, veterinarians, animal and wildlife control workers, long-term travellers to endemic areas
 - eliminates need for HRIG following an exposure, and reduces number of HDCV PEP shots from 4 to 2

Systemic Infections

Sepsis and Septic Shock

- see [Respirology, R34](#)

Definitions

- systemic inflammatory response syndrome (SIRS): 2 or more of
 1. temperature $<36^{\circ}\text{C}/96.8^{\circ}\text{F}$ or $>38^{\circ}\text{C}/100.4^{\circ}\text{F}$
 2. heart rate >90 beats/min
 3. respiratory rate >20 breaths/min or $\text{P}_a\text{CO}_2 <32$ mmHg
 4. WBC $<4 \times 10^9/\text{L}$ or $>12 \times 10^9/\text{L}$ or $>10\%$ bands
- sepsis: SIRS + proven or provable infection
- severe sepsis: sepsis + signs of end-organ dysfunction and hypoperfusion
- septic shock: severe sepsis + hypotension (<90 mmHg sBP), despite adequate fluid resuscitation

Pathophysiology

- causative agents are identified in only 50-70% of cases
- when organisms are identified, GP and GN organisms are the cause in 90% of cases
- primary bloodstream infection or secondary bacteremia \rightarrow local immune response \rightarrow immune cells release pro-inflammatory cytokines \rightarrow immune response spreads beyond local environment \rightarrow unregulated, exaggerated systemic immune response \rightarrow vasodilation and hypotension \rightarrow involvement of tissues remote from the site of injury/infection resulting in multiple major organ dysfunction \rightarrow periodic immunoparalysis

Clinical Presentation

- history: fever, chills, dyspnea, cool extremities, fatigue, malaise, anxiety, confusion
- physical: abnormal vitals (fever, tachypnea, tachycardia, hypotension), local signs of infection

Investigations

- CBC and differential, electrolytes, BUN, creatinine, liver enzymes, ABG, lactate, INR, PTT, FDP, blood C&S x2, urinalysis, urine C&S and cultures of any wounds or lines
- CXR (other imaging depends on suspicion of focus of infection)

Treatment (see **Respirology, R34**)

- respiratory support: O₂ ± intubation
- cardiovascular support: IV fluids, ± norepinephrine + ICU
- IV antibiotics (empirical, depends on suspected source)
 - start with broad spectrum antibiotics (piperacillin/tazobactam or meropenem) ± additional agents depending on patient risk factors, suspected etiology of infection, and local microbial susceptibilities (± aminoglycoside for drug-resistant GNs or vancomycin for MRSA)
 - narrow once susceptibilities are known
- hydrocortisone IV in patients with septic shock unresponsive to fluid resuscitation and vasopressors

Leprosy (Hansen's Disease)

Etiology

- *Mycobacterium leprae*: obligate intracellular bacteria, slow-growing (doubling time 12.5 d), survives in macrophages
- bacteria transmitted from nasal secretions, potentially via skin lesions
- invades skin and peripheral nerves leading to chronic granulomatous disease

Clinical Presentation

- lesions involve cooler body tissues (e.g. skin, superficial nerves, nose, eyes, larynx)
- spectrum of disease determined by host immune response to infection
 - i. paucibacillary "tuberculoid" leprosy (intact cell-mediated immune response)
 - ♦ ≤5 hypoesthetic lesions, usually hypopigmented, well-defined, dry
 - ♦ early nerve involvement, enlarged peripheral nerves, neuropathic pain
 - ♦ may be self-limited, stable, or progress over time to multibacillary "lepromatous" form
 - ii. multibacillary "lepromatous" leprosy (weak cell-mediated immune response)
 - ♦ ≥6 lesions, symmetrical distribution
 - ♦ leonine facies (nodular facial lesions, loss of eyebrows, thickened ear lobes)
 - ♦ extensive cutaneous involvement, late and insidious nerve involvement causing sensory loss at the face and extremities
 - iii. borderline leprosy
 - ♦ lesions and progression lies between tuberculoid and lepromatous forms

Investigations

- skin biopsy down to fat or slit skin smears for AFB staining, PCR
- histologic appearance: intracellular bacilli in spherical masses (lepra cells), granulomas involving cutaneous nerves

Treatment (WHO Treatment Regimens)

- paucibacillary: dapsone daily + rifampin monthly x 6 mo
- single skin lesion paucibacillary: single dose of rifampicin, ofloxacin, and minocycline
- multibacillary: dapsone + rifampin monthly + clofazimine monthly x 12 mo AND low dose clofazimine once daily x 12 mo
- treatment of leprosy can cause an immune reaction to killed or dying bacteria (e.g. erythema nodosum leprosum and reversal reaction): symptomatic management with NSAIDs if mild, prednisone with 6-12 wk taper if severe; thalidomide for erythema nodosum leprosum

Prognosis

- curable with WHO-approved treatment regimens
- complications: muscle atrophy, contractures, trauma/superinfection of lesions, crippling/loss of limbs, erythema nodosum leprosum, social stigmatization due to clofazimine hyperpigmentation
- long post-treatment follow-up warranted to monitor for relapse and immune reactions

Lyme Disease

Etiology/Epidemiology

- spirochete bacteria: *Borrelia burgdorferi* (N. America), *B. garinii*, *B. afzelii* (Europe and Asia)
- transmitted by *Ixodes* tick
- reported in 49 of the 50 U.S. states, but most cases occur in the Northeast, the Midwest, and Northern California
- in Canada, reported in southern and southeastern Quebec, southern and eastern Ontario, southeastern Manitoba, New Brunswick and Nova Scotia, as well as southern British Columbia
- small rodents (mice) serve as primary reservoir, while larger animals (white-tailed deer) serve as hosts for ticks
- human contact usually May-August in fields with low brush near wooded areas
- infection usually requires >36 h tick attachment

Clinical Presentation

- stage 1 (early localized stage: 7-14 d post-bite)
 - malaise, fatigue, H/A, myalgias
 - erythema migrans: expanding, non-pruritic bulls-eye (target) lesions (red with clear centre) on thigh/groin/axilla
- stage 2 (early disseminated stage): weeks post-infection
 - CNS: aseptic meningitis, CN palsies (CN VII palsy), peripheral neuritis
 - cardiac: transient heart block or myocarditis
- stage 3 (late persistent stage: months to years post-infection)
 - may not have preceding history of early stage infection
 - MSK: chronic monoarticular or oligoarticular arthritis
 - acrodermatitis chronica atrophicans (due to *B. afzelii*)
 - neurologic: encephalopathy, meningitis, neuropathy

Investigations

- serology: ELISA, Western blot

Prevention

- use of protective clothing (tuck pants into socks), insect repellent, inspection for ticks and prompt removal of tick
- doxycycline prophylaxis within 72 h of removal of an engorged, *Ixodes scapularis* tick in hyperendemic area (local rate of infection of ticks $\geq 20\%$) for patients >8 yr who are not pregnant or lactating

Treatment

- stage 1: doxycycline/amoxicillin/cefuroxime
- stage 2-3: ceftriaxone

BAKE a Key Lyme Pie

Bell's palsy
Arthritis
Kardiac block
Lyme
Erythema chronicum migrans

Toxic Shock Syndrome

Etiology

- superantigens produced by some strains of *S. aureus* or GAS cause widespread T-cell activation and pro-inflammatory cytokine release (IL-1, IL-6, TNF)
- course of disease is precipitous and leads to acute fever, shock, multiorgan failure
- Staphylococcal TSS involves the production of superantigen TSST-1 (toxic shock syndrome toxin 1)
- Streptococcal TSS involves the production of superantigens SPEA, SPEB, SPEC

Risk Factors

- Staphylococcal: tampon use, nasal packing, wound infections (e.g. postpartum vaginal or Cesarean or other surgical infections)
- Streptococcal: minor trauma, surgical procedures, preceding viral illness (e.g. chickenpox), use of NSAIDs

Clinical Presentation and Investigations

- acute onset
- Staphylococcal TSS
 - T >38.9°C
 - sBP <90 mmHg
 - diffuse erythroderma with subsequent desquamation, especially on palms and soles
 - involvement of 3 or more organ systems: GI (vomiting, diarrhea), muscular (myalgia, increased CK), mucous membranes (hyperemia), renal, hepatic, hematologic (thrombocytopenia), CNS (disorientation)
 - isolation of *S. aureus* is not required for diagnosis (*S. aureus* is rarely recovered from blood in TSS)

- Streptococcal TSS
 - sBP <90 mmHg
 - isolation of GAS from a normally sterile site (e.g. blood, pleural, tissue biopsy, or surgical wound)
 - ≥2 of coagulopathy, liver involvement, ARDS, soft tissue necrosis (necrotizing fasciitis, myositis, gangrene), renal impairment, erythematous macular rash that may desquamate

Treatment

- supportive: fluid resuscitation
- Staphylococcal: for methicillin-susceptible *S. aureus*: clindamycin + cloxacillin (IV); for MRSA: clindamycin + vancomycin x 10-14 d
- Streptococcal: IV penicillin and clindamycin and ± IVIg

Cat Scratch Disease

Etiology

- *Bartonella henselae*: intracellular bacteria
- cat-to-human transmission via cat scratch/bite

Clinical Presentation

- skin lesion appears 3-10 d post-inoculation
- may be followed by fever, tender regional lymphadenopathy
- in some patients, organism may disseminate causing fever of unknown origin, hepatosplenomegaly, retinitis, encephalopathy
- usually self-limited

Investigations

- serology, PCR, lymph node biopsy

Treatment

- the disease may be self-limited but treatment is recommended by the Infectious Disease Society of America with a 5 d course of azithromycin for immunocompetent patients with mild to moderate illness
- needle aspiration of painful suppurative lymph nodes may hasten the relief of symptoms
- combination therapy consisting of doxycycline or azithromycin plus rifampin often used for disseminated disease (neuroretinitis, hepatosplenic involvement)

Rocky Mountain Spotted Fever

Etiology

- *Rickettsia rickettsii*: obligate intracellular GN organism
- reservoir hosts: rodents, dogs
- vectors: *Dermacentor* ticks
- organisms cause inflammation of endothelial lining of small blood vessels, leading to small hemorrhages and thrombi
- can cause widespread vasculitis leading to H/A, and CNS changes; can progress to death if treatment is delayed

Clinical Presentation

- usually occurs in summer following tick bite
- influenza-like prodrome: acute onset fever, H/A, myalgia, N/V, anorexia
- macular rash appearing on day 2-4 of fever
 - begins on wrists and ankles, then spreads centrally to arms/legs/trunk/palms/soles
 - occasionally "spotless" (10% of patients)

Investigations

- skin biopsy and serology (indirect fluorescent antibody test)

Treatment

- doxycycline, usually 5-7 d (treat for 3 d after defervescence)

West Nile Virus

Epidemiology

- virus has been detected throughout the United States and much of southern Canada
- overall case-fatality rates in severe cases is ~10%

Transmission

- primarily from mosquitoes that have fed on infected birds (crows, blue jays)
- transplacental, blood products (rare), organ transplantation

Clinical Presentation

- most are asymptomatic
- most symptomatic cases are mild (West Nile fever): acute onset of H/A, back pain, myalgia, anorexia, maculopapular non-pruritic rash involving chest, back, arms
- severe complications: encephalitis, meningoenzephalitis, and acute flaccid paralysis (especially in those >60 yr)

Investigations

- IgM antibody in serum or CSF (cross reactivity with yellow fever and Japanese encephalitis vaccines, and with dengue fever and St. Louis virus infection); may not reflect current illness as IgM antibody can last for >6 mo
- viral isolation by PCR from CSF, tissue, blood, and fluids (all have low sensitivity)
- CSF: elevated lymphocytes and protein if CNS involvement

Treatment and Prevention

- treatment: supportive
- prevention: mosquito repellent (DEET), drain stagnant water, community mosquito control programs

Syphilis

Etiology

- *Treponema pallidum*: thick motile spirochetes historically detectable by dark-field microscopy
- transmitted sexually, vertically, or parenterally (rare)

Clinical Presentation

- see [Dermatology, D31](#) and [Gynecology, GY30](#)
- multi-stage disease
 1. primary syphilis (3-90 d post-infection)
 - painless chancre at inoculation site (any mucosal surface)
 - regional lymphadenopathy
 - acute disease lasts 3-6 wk, 25% progress to secondary syphilis without treatment
 2. secondary syphilis = systemic infection (2-8 wk following chancre)
 - maculo-papular non-pruritic rash including palms and soles
 - generalized lymphadenopathy, low grade fever, malaise, H/A, aseptic meningitis, ocular/otic syphilis
 - condylomata lata: painless, wart-like lesion on palate, vulva, or scrotum (highly infectious)
 3. latent syphilis
 - asymptomatic infection that follows untreated primary/secondary syphilis
 - early latent (<1 yr post-infection) or late latent/unknown duration (>1 yr post-infection)
 - increased transmission risk with early latent; longer treatment duration required for late latent
 4. tertiary syphilis (1-30 yr post-infection)
 - gummatous syphilis: nodular granulomas of skin, bone, liver, testes, brain
 - aortic aneurysm and aortic insufficiency
 - neurosyphilis: dementia, personality changes, Argyll-Robertson pupils, tabes dorsalis
 5. congenital syphilis
 - causes spontaneous abortions, stillbirths, congenital malformations, developmental delay, deafness
 - most infected newborns are asymptomatic
 - clinical manifestation in early infancy include rhinitis (snuffles), lymphadenopathy, hepatosplenomegaly, pseudoparalysis (bone pain associated with osteitis) and rash (usually maculopapular and involving palms and soles)
 - late onset manifestations (>2 yr of age) include saddle nose, saber shins, Glutton joints, Hutchinson's teeth, mulberry molars, rhagades, CN VIII deafness, interstitial keratitis, juvenile paresis

Investigations

- screening tests: CMIA, CLIA, EIA (treponemal), RPR, or VDRL (non-treponemal)
- confirmatory tests: TPPA, FTA-ABS, MHA-TP, TPI, dark field microscopy with silver stain (rarely)
- LP for neurosyphilis if: seropositive and symptoms of neurosyphilis or treatment failure/other tertiary symptoms, or with HIV and late latent/unknown duration syphilis; consider in others
- for congenital syphilis, LP is essential; long bone x-rays may also be helpful

Treatment

- for 1^o, 2^o, early latent: benzathine penicillin G 2.4 million units IM x 1
- for 3^o, late latent: benzathine penicillin G 2.4 million units IM weekly x 3
- if allergic to penicillin: doxycycline 100 mg PO bid x 14 d
- neurosyphilis: aqueous Penicillin G 18-24 million units/d IV x 14 d
- for congenital syphilis, penicillin G IV x 10 d
- see [Family Medicine, FM42](#) for generalized STI workup

Argyll Robertson Pupil

Accommodates but does not react to light

Those with Untreated 1^o or 2^o Syphilis

1/3 cure
1/3 latent indefinitely
1/3 3^o syphilis

Causes of False Positive VDRL and RPR Tests

Viruses (mononucleosis, hepatitis)
Drugs and substance abuse
Rheumatic fever
Lupus and leprosy

Patients with 2^o or 3^o syphilis treated with penicillin may experience a Jarisch-Herxheimer reaction. Lysis of organisms release pyrogens thought to cause fever, chills, myalgia, flu-like symptoms may last up to 24 h

VDRL	Venereal Disease Research Laboratory
RPR	Rapid Plasma Reagin
EIA	Enzyme Immunoassay
CLIA	Chemiluminescent ImmunoAssay
CMIA	Chemiluminescent Microparticle ImmunoAssay
FTA-ABS	Fluorescent Treponema Antibody-Absorption
MHA-TP	Microhemagglutination Assay <i>T. pallidum</i>
TPPA	<i>T. pallidum</i> Particle Agglutination Assay
TPI	<i>T. pallidum</i> immobilization test

Tuberculosis

Etiology, Epidemiology, and Natural History

- 1/3 of the world's population is infected with TB
- contracted by aerosolized inhalation of *Mycobacterium tuberculosis*, a slow growing aerobe (doubling time = 18 h) that can evade innate host defenses, survive, and replicate in macrophages
- inhalation and deposition in the lung can lead to one of the following outcomes
 1. immediate clearance of the pathogen
 2. latent TB: asymptomatic infection contained by host immune defenses (represents 95% of infected people)
 3. primary TB: symptomatic, active disease (represents 5% of infected people)
 4. secondary TB: symptomatic reactivation of previously dormant TB (represents 5-10% of those with latent TB, most often within the first 1-2 yr of initial infection) at a pulmonary or extrapulmonary site

Tuberculous Polyserositis

pleural + pericardial + peritoneal effusions
(usually from granuloma breakdown that spills TB into pleural cavity – very rare)

Figure 8. Tuberculosis statistics
Canadian Tuberculosis Standards, 7th ed.

Risk Factors

- social and environmental factors
 - travel or birth in a country with high TB prevalence (e.g. Asia, Latin America, Sub-Saharan Africa, Eastern Europe)
 - Aboriginal (particularly Inuit), crowded living conditions, low SES/homeless, IVDU
 - personal or occupational contact
- host factors
 - immunocompromised/immunosuppressed (especially HIV, including extremes of age)
 - silicosis
 - chronic renal failure requiring dialysis
 - malignancy and chemotherapy
 - substance abuse (e.g. drug use, alcoholism, smoking)

Clinical Presentation

- primary infection usually asymptomatic, although progressive primary disease may occur, especially in children and immunosuppressed patients
- secondary infection/reactivation usually produces constitutional symptoms (fatigue, anorexia, night sweats, weight loss) and site-dependent symptoms
 1. pulmonary TB
 - chronic productive cough ± hemoptysis
 - CXR consolidation or cavitation, lymphadenopathy
 - non-resolving pneumonia despite standard antimicrobial therapy
 2. miliary TB
 - widely disseminated spread especially to lungs, abdominal organs, marrow, CNS
 - CXR: multiple small 2-4 mm millet seed-like lesions throughout lung
 3. extrapulmonary TB
 - lymphadenitis, pleurisy, pericarditis, hepatitis, peritonitis, meningitis, osteomyelitis (vertebral = Pott's disease), adrenal (causing Addison's disease), renal, ovarian

Investigations

- screening for latent TB
 - PPD/Mantoux skin tests
 - ♦ both tests diagnose prior TB exposure; neither can diagnose or exclude active disease

- IFN- γ release assay (IGRA)
 - ♦ in patients previously infected with TB, T-cells produce increased amounts of IFN- γ when re-exposed to TB antigen
 - ♦ detects antigen not present in the BCG vaccine or in most types of non-tuberculous-*Mycobacteria* (NTM), therefore fewer false positives
- Canadian and American guidelines treat IGRAs as equivalent to the TB skin test and preferable in patients with a history of BCG vaccination or who may not return for a skin test reading
- diagnostic tests/investigations for active pulmonary TB
 - three sputum specimens (either spontaneous or induced) should be collected for acid-fast bacilli smear and culture; the three specimens can be collected on the same day, a minimum of 1 hour apart
 - BAL
 - CXR
 - ♦ nodular or alveolar infiltrates with cavitation (middle/lower lobe if primary, apical if secondary)
 - ♦ pleural effusion (usually unilateral and exudative) may occur independently of other radiograph abnormalities
 - ♦ hilar/mediastinal adenopathy (especially in children)
 - ♦ tuberculoma (semi-calcified well-defined solitary coin lesion 0.5-4 cm that may be mistaken for lung CA)
 - ♦ miliary TB (see clinical features)
 - ♦ evidence of past disease: calcified hilar and mediastinal nodes, calcified pulmonary focus, pleural thickening with calcification, apical scarring

Prevention

- primary prevention
 - airborne isolation for active pulmonary disease
 - BCG vaccine
 - ♦ ~80% effective against pediatric miliary and meningeal TB
 - ♦ effectiveness in adults debated (anywhere from 0-80%)
 - ♦ recommended in high-incidence communities in Canada for infants in whom there is no evidence of HIV infection or immunodeficiency; widely used in other countries
- secondary prevention (defer in pregnancy unless mother is high risk)
 - likely INH-sensitive: isoniazid (INH) + pyridoxine (vit B6 to help prevent INH-associated neuropathy) x 9 mo
 - likely INH-resistant: rifampin x 4 mo

Treatment of Active Infection

- pulmonary TB: INH + rifampin + pyrazinamide + ethambutol + pyridoxine x 2 mo (initiation phase), then INH + rifampin + pyridoxine x 4 mo in fully susceptible TB (continuation phase), total 6 mo
- extrapulmonary TB: same regimen as pulmonary TB but increase to 12 mo in bone/joint, CNS, and miliary/disseminated TB + corticosteroids for meningitis, pericarditis
- empiric treatment of suspected MDR (multidrug resistant) or XDR (extensively drug-resistant) TB requires referral to a specialist
 - MDR = resistance to INH and rifampin \pm others
 - XDR = resistance to INH + rifampin + fluoroquinolone + ≥ 1 of injectable, second-line agents
 - ♦ very difficult to treat, global public health threat, 5 documented cases in Canada from 1997-2008
 - suspect MDR TB if previous treatment, exposure to known MDR index case, or immigration from a high-risk area
- note: TB is a reportable disease to Public Health (please see Public Health Agency of Canada website for more information: www.phac-aspc.gc.ca/tbpc-latb/pubs/tb-canada-7/index-eng.php)

Positive PPD Test

If induration at 48-72 h

> 5 mm if immunocompromised, close contact with active TB
> 10 mm all others; positive PPD \rightarrow CXR; decision to treat depends on individual risk factors

False(-): poor technique, anergy, immunosuppression, infection < 10 wk or remotely

False(+): BCG after 12 mo of age in a low-risk individual, NTM

Booster effect: initially false(-) result boost to a true(+) result by the testing procedure itself (usually if patient was infected long ago so had diminished delayed type hypersensitivity reaction or if history of BCG)

HIV and AIDS

Epidemiology

Canadian Situation (Public Health Agency of Canada, 2013)

- estimated 71,300 Canadians living with HIV infection at the end of 2011, 25% unaware of HIV-positive status
- 2,090 new infections were reported in 2013: MSM account for 49.3% of cases, IVDU 12.8%

Global Situation (WHO and UNAIDS Core Epidemiology Slides, July 2014)

- estimated 35 million people living with HIV/AIDS in 2013
- estimated 2.1 million newly infected in 2013
- estimated 1.5 million AIDS-related deaths in 2013

HIV-1 is the predominant type in North America and most of the world

HIV-2 is found mainly in West Africa

Both lead to AIDS but HIV-2 is generally less virulent

Etiology

- HIV is a retrovirus that causes progressive immune system dysfunction which predisposes patients to various opportunistic infections and malignancies
- HIV virion includes an envelope (gp41 and gp120 glycoproteins), matrix (p17) and capsid (p24) enclosing 2 single-stranded copies of RNA plus enzymes in its core
- virion glycoproteins bind CD4 and CCR5/CXCR4 on CD4+ T lymphocytes (T-helper cells) to fuse and enter the cells
- RNA converted to dsDNA by viral reverse transcriptase; dsDNA is integrated into host genome by viral integrase
- virus DNA transcribed and translated using host cell machinery, post-translational modifications include proteolytic activity of virally encoded protease enzymes
- newly produced virions bud out of host cell, incorporating host cell membrane; additional maturation steps are required before virion is considered infectious
- exact mechanisms of CD4 depletion incompletely characterized but likely include direct viral cytopathic effects, apoptosis, and increased cell turnover

p24 = capsid protein
gp41 = fusion and entry
gp120 = attachment to host T-cell

Homozygosity for A32 mutation in CCR5 gene confers relative resistance to HIV infection
Heterozygosity for A32 mutation in CCR5 gene associated with slower disease course

Modes of Transmission

Table 20. Modes of Transmission in Adolescents and Adults by Site and Medium

HIV Invasion Site	Sub-Location	Transmission Medium	Transmission Probability per Exposure Event
Female genital tract	Vagina, ectocervix, endocervix	Semen	1 in 200 to 1 in 2,000
Male genital tract	Inner foreskin, penile urethra	Cervicovaginal and rectal secretions and desquamations	1 in 700 to 1 in 3,000
Intestinal tract	Rectum, upper GI tract	Semen	1 in 20 to 1 in 300
		Semen	1 in 2,500
		Maternal blood/genital secretions (intrapartum) Breastmilk	1 in 5 to 1 in 10
Placenta	Chorionic villi	Maternal blood (intrauterine)	1 in 10 to 1 in 20
Blood stream		Contaminated blood products	95 in 100
		Sharp/needlestick injuries	1 in 150

Adapted with permission from Macmillan Publishers Ltd. Nat Rev Immunology 2008;8:447-457

NOTE: these estimates are for "all comers" i.e. they estimate transmission risk for anyone with HIV infection and do not take into account treatment status of the HIV+ person (in contrast to results of PARTNER study)

Natural History

Figure 10. Relationships between CD4 T-cell count, viral load, and anti-HIV antibodies

Acute (Infection) Retroviral Syndrome

- 40-90% experience an acute "flu-like" illness (may include fever, pharyngitis, lymphadenopathy, rash, arthralgias, myalgias, H/A, GI symptoms, oral ulcers, weight loss) 2-6 wk post-exposure lasting 10-15 d
- hematologic disturbances (lymphopenia, thrombocytopenia)
- 10-20% present with aseptic meningitis; HIV RNA and/or p24 may be detected in CSF
- associated with a high level of plasma viremia and therefore high risk of transmission

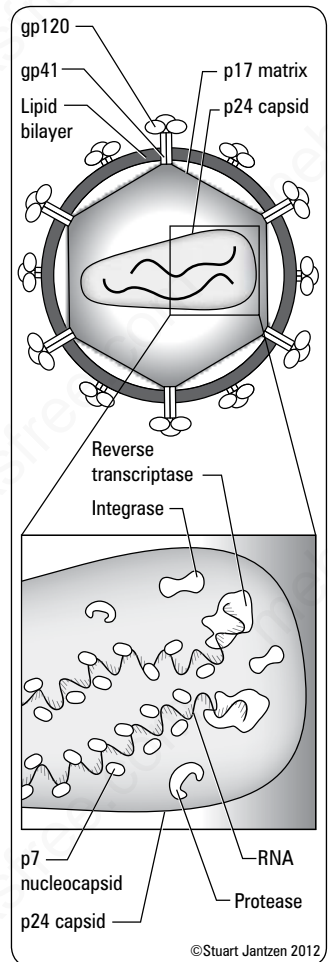

Figure 9. HIV viral particle

Asymptomatic (Latent) Stage

- during latent phase, HIV infects and replicates in CD4+ T lymphocytes (lymph nodes)
- normal CD4 count in adults: 500-1,100 cells/mm³
- CD4 count drops 60-100 cells/mm³ per year
- by 10 yr post-infection, 50% have AIDS, 30% demonstrate milder symptoms, and <20% are asymptomatic if left untreated

Definition of AIDS

- HIV-positive AND
- one or more of the clinical illnesses that characterize AIDS, including: opportunistic infections (e.g. PJP (previously PCP), esophageal candidiasis, CMV, MAC, TB, toxoplasmosis), malignancy (Kaposi's sarcoma, invasive cervical cancer), wasting syndrome
- OR CD4 <200 (or <15%); this is largely historical since ART can reverse CD4 count decline

Table 21. Symptomatic Stage (CD4 count thresholds for classic clinical manifestations)

CD4 Counts	Possible Manifestations
<500 cells/mm ³	Often asymptomatic Constitutional symptoms: fever, night sweats, fatigue, weight loss Mucocutaneous lesions: seborrheic dermatitis, HSV, VZV (shingles), oral hairy leukoplakia (EBV), candidiasis (oral, esophageal, vaginal), Kaposi's sarcoma (KS) Recurrent bacterial infections, especially pneumonia Pulmonary and extrapulmonary tuberculosis Lymphoma
<200 cells/mm ³	<i>Pneumocystis jirovecii</i> pneumonia (formerly PCP) KS Oral thrush Local and/or disseminated fungal infections: <i>Cryptococcus neoformans</i> , <i>Coccidioides immitis</i> , <i>Histoplasma capsulatum</i>
<100 cells/mm ³	Progressive multifocal leukoencephalopathy (PML) – JC virus CNS toxoplasmosis
<50 cells/mm ³	CMV infection: retinitis, colitis, cholangiopathy, CNS disease <i>Mycobacterium avium</i> complex (MAC) <i>Bacillary angiomatosis</i> (disseminated <i>Bartonella</i>) Primary central nervous system lymphoma (PCNSL)

Laboratory Diagnosis

- anti-HIV antibodies detectable after a median of 3 wk, virtually all by 3 mo (therefore 3 mo window period)
- initial screening test (3rd generation antibody test): enzyme linked immunosorbent assay (ELISA) detects serum antibody to HIV; sensitivity >99.5%
- increasingly, combination p24 antigen/HIV antibody tests (4th generation) used for screening; improved sensitivity in early or acute infection and sensitivity/specificity approach 100% for chronic infection
- confirmatory test: if positive screen, Western blot confirmation by detection of antibodies to at least two different HIV protein bands (p24, gp41, gp120/160); specificity >99.99%
- rapid (point of care) antibody tests: higher false positives, therefore need to confirm positive results with traditional serology
- p24 antigen: detection by ELISA may be positive during "window period"

Management of the HIV-Positive Patient

- verify positive HIV test
- complete baseline history and physical exam, then follow-up every 3-6 mo
- laboratory evaluation
 - routine CD4 count to measure status of the immune system
 - routine HIV-RNA levels (viral load)
 - also important indicator of effect of ART
 - baseline HIV resistance testing to guide ARV therapy
 - HLA-B*5701 genetic test to screen for abacavir hypersensitivity if considering abacavir in treatment regimen
 - CCR5 tropism testing if considering CCR5 antagonist in treatment regimen
 - baseline tuberculin skin test (PPD): induration greater than 5 mm is positive
 - baseline serologies (hepatitis A, B, and C, syphilis, toxoplasmosis, CMV, VZV)
 - routine biochemistry and hematology, CXR, urinalysis
 - annual fasting lipid profile and fasting glucose (due to ART side effects)
- education
 - regular follow-up on CD4 counts and viral loads (q3-6mo) as well as strict adherence to ART improves prognosis
 - prevention of further transmission through safer sex and clean needles for IVDU
 - HIV superinfection (transmission of different HIV strains from another HIV+ person) does rarely occur so barrier protection during sex is still recommended
 - discuss importance of disclosing HIV status to partners including risk of criminal prosecution of non-disclosure in jurisdictions where applicable
 - connect to relevant community groups and resources

PARTNER Study: Risk of HIV Transmission Between Serodiscordant Couples with HIV+ Partner on ART

Preliminary results presented at Conference on Retroviruses and Opportunistic Infections 2014 (CROI 2014); final results due 2017

Participants: 740 serodiscordant heterosexual (60% of couples) and homosexual couples (40% of couples) that engage in sex without using condoms. The HIV- partner cannot be using pre- or post-exposure prophylaxis and the HIV+ partner must be on ART with an undetectable viral load.

Methods: Partners enrolled in the study are asked to independently complete a questionnaire on sexual behaviour with their partner every 3-6 mo. Additionally, if the HIV- partner seroconverts, a blood sample will be taken from each partner and the viruses genotyped for comparison. To remain in the study, the requirements for participation must be maintained.

Results: No HIV transmissions within couples from a partner with an undetectable viral load in an estimated 16,400 occasions of sex in MSM and 28,000 occasions of sex in the heterosexual couples. If the HIV+ partners had not been on treatment in this group, 50-100 (median: 86) transmissions would have been expected in the MSM group and 15 transmissions in heterosexual couples. In a couple whose sexual activity is considered as average for the group studied, there was a 95% chance that the greatest-possible risk of transmission from a partner was 0.45% per year as well as 1% per year from anal sex.

Seroconversion: Development of detectable anti-HIV antibodies

Window Period: Time between infection and development of anti-HIV antibodies; when serologic tests (ELISA, Western blot) are negative

All infants born to HIV infected mothers have positive ELISA tests because of circulating maternal anti-HIV antibodies, which disappear by 18 mo; early diagnosis is made by detection of HIV RNA in plasma

HLA-B*5701 Testing

Abacavir hypersensitivity reactions usually only occur in individuals carrying this HLA allele (~5-7% of Caucasians, lower prevalence in other ethnic groups). Routine screening for HLA-B*5701 at baseline and definitely prior to abacavir use

HIV Status

- CD4 count: progress and stage of disease
- Viral load: rate of progression

- health care maintenance
 - assessment of psychosocial concerns and referral to psychiatry or social work if appropriate
 - vaccines: influenza annually, 23-valent pneumococcal every 5 yr, HBV (if not immune), HAV (if seronegative)
 - annual screening (PAP smear, STIs)
 - management of comorbid conditions and provision of general primary care

Table 22. Prophylaxis Against Opportunistic Infections in HIV-infected Patients

Pathogen	Indication for Prophylaxis	Prophylactic Regimen
<i>Pneumocystis jiroveci</i>	CD4 count <200 cells/mm ³ or history of oral candidiasis	TMP-SMX 1 SS or DS OD
<i>Toxoplasma gondii</i>	IgG antibody to <i>Toxoplasma</i> and CD4 count <100 cells/mm ³	TMP-SMX 1 DS OD
<i>Mycobacterium tuberculosis</i>	PPD reaction >5 mm or contact with case of active TB	INH + pyridoxine daily x 9 mo
<i>Mycobacterium avium</i> complex	CD4 count <50 cells/mm ³	Azithromycin 1,200 mg q1wk

SS = single strength; DS = double strength

See USPHS/IDSA guidelines for preventing opportunistic infections among HIV-infected persons (Relevant Sections updated 2013, 2015). Available from: <http://aidsinfo.nih.gov/>

1° and 2° prophylaxis may be discontinued if CD4 count is above threshold for ≥6 mo while on ART

Anti-Retroviral pre-exposure prophylaxis (PrEP) for preventing HIV in high-risk individuals

Cochrane DB Syst Rev 2012 Jul 11;7:CD007189.

Purpose: To evaluate the efficacy of oral anti-retroviral prophylactic therapy in preventing HIV infection.

Study: Systematic review of 12 randomized controlled trials with 6 trials forming the core analysis.

Population: 9849 HIV-uninfected patients at high risk of contracting HIV including men who have sex with men, serodiscordant couples and others.

Outcome: New infection with HIV.

Results: Daily oral tenofovir disoproxil fumarate (TDF) plus emtricitabine (FTC) reduced the risk of HIV acquisition compared to placebo (RR 0.49; 95% CI 0.28-0.85). TDF alone also showed significant risk reduction in trials with fewer patients (RR 0.33; 95% CI 0.20-0.55). There was no significant increase in adverse events in any of the treatment groups. Sexual practices and adherence did not differ between treatment and placebo arms.

Conclusions: Pre-exposure prophylaxis with TDF with or without FTC effectively reduces the risk of HIV acquisition in high risk, HIV uninfected patients without causing significant adverse effects.

Reasons for Deterioration of a Patient with HIV/AIDS

- Opportunistic infections
- Neoplasms
- Medication-related toxicities
- Co-infections (e.g. HBV, HCV, STIs)
- Non-AIDS-related comorbidities (e.g. cardiovascular, renal, hepatic, neurocognitive, bone disease)

Treatment Failure

- Assess adherence
- Assess drug interactions
- Resistance testing
- Rule out opportunistic infections
- Rule out marrow suppression
- Construct new 3-drug regimen

Anti-Retroviral Treatment

Overall Treatment Principles

- recommended that all HIV+ patients initiate combination ART to restore and preserve immune function, reduce morbidity, prolong survival and prevent transmission
- patients starting ART should be committed to treatment and understand the importance of adherence; poor compliance can lead to viral resistance; may defer treatment on the basis of clinical and psychosocial factors on case by case basis
- consider results of baseline resistance testing and complete ART history before (re-) initiating ART
- goal: keep viral load below limit of detection i.e. <40 copies/mL (undetectable); viral load should decrease 10-fold within 4-8 wk, be undetectable by 6 mo, and restore immunological function
- strong evidence against intermittent ART or 'drug holidays'
- ART leads to 96% reduction in risk of transmitting HIV to sexual partners

ART Recommendations for Treatment of Naïve Patients

- 2 NRTIs + 1 INSTI/PI (boosted with ritonavir or cobicistat)

Treatment Failure

- defined primarily by viral load (persistently >200 copies/mL)
- ensure that viral load >40 is not just a transient viremia or 'blip'; confirm medication adherence, assess drug interactions, perform resistance testing

Table 23. Anti-Retroviral Drugs

Class	Drugs	Mechanism	Adverse Effects
Nucleoside reverse transcriptase inhibitors (NRTIs)	zidovudine (AZT) lamivudine (3TC) stavudine (d4T) didanosine (ddI) abacavir (ABC) emtricitabine (FTC) tenofovir disoproxil fumarate (TDF) Combination Tablets: AZT/3TC (Combivir®) AZT/3TC/ABC (Trizivir®) ABC/3TC (Kivexa®) TDF/FTC (Truvada®)	Incorporated into the growing viral DNA chain, thereby competitively inhibiting reverse transcriptase and terminating viral DNA growth	Lactic acidosis Lipodystrophy Rash N/V/diarrhea Bone marrow suppression (AZT) Peripheral neuropathy (ddI, d4T) Drug-induced hypersensitivity (ABC) Pancreatitis (ddI/d4T) Myopathy (AZT)
Non-nucleoside reverse transcriptase inhibitors (NNRTIs)	efavirenz (EFZ) nevirapine (NVP) delavirdine (DLV) etravirine (ETR) rilpivirine (RPV)	Non-competitively inhibit function of reverse transcriptase, thereby preventing viral RNA replication	Rash, Stevens-Johnson syndrome CNS: dizziness, insomnia, somnolence, abnormal dreams (efavirenz) Hepatotoxicity (nevirapine – avoid in females with CD4 > 250, men with CD4 > 400) CYP3A4 interactions
Protease inhibitors (PIs)*	ritonavir (RTV) saquinavir (SQV) amprenavir (APV) nelfinavir (NFV) indinavir (IDV) atazanavir (ATV) fosamprenavir (FPV) lopinavir/ritonavir (Kaletra®) tipranavir (TPV) darunavir (DRV)	Prevent maturation of infectious virions by inhibiting the cleavage of polyproteins	Lipodystrophy, metabolic syndrome N/V/diarrhea Nephrolithiasis (indinavir) Rash (APV) Hyperbilirubinemia (atazanavir, indinavir) CYP3A4 interactions Hyperlipidemia
Fusion inhibitor	enfuvirtide (T-20)	Inhibit viral fusion with T-cells by inhibiting gp41, preventing cell infection	Injection site reactions, rash, infection, diarrhea, nausea, fatigue
CCR5 antagonist	maraviroc	Inhibit viral entry by blocking host CCR5 co-receptor	Fever, cough, dizziness
Integrase strand transfer inhibitors (INSTIs)	raltegravir elvitegravir dolutegravir bictegravir	Inhibits integration of HIV DNA into the human genome thus preventing HIV replication	

*Standard of care is to pharmacologically boost most PIs with ritonavir to increase concentrations

Single Tablet ART Regimens

- reduces pill burden and increases adherence
- generally better tolerated

Table 24. Single Tablet ART Regimens

Name	Contents	Common Side Effects
Atripla®	efavirenz/tenofovir/emtricitabine	psychiatric events, vivid dreams
Complera®	rilpivirine/emtricitabine/tenofovir	good side effect profile
Odefsey®	rilpivirine/emtricitabine/tenofovir alafenamide	good side effect profile
Stribild®	elvitegravir/cobicistat/emtricitabine/tenofovir	good side effect profile
Triumeq®	dolutegravir/abacavir/lamivudine	good side effect profile; use only in HLAB*5701 negative patients
Genvoya®	tenofovir/emtricitabine/elvitegravir/cobicistat	good side effect profile

Lactic Acidosis

- Occurs secondary to mitochondrial toxicity
- Symptoms include abdominal pain, fatigue, N/V, muscle weakness

Lipodystrophy

Body fat redistribution (mainly with old ARVs)

- Lipohypertrophy (e.g. dorsal fat pad, breast enlargement, increased abdominal girth) thought to be caused primarily by protease inhibitors
- Lipodystrophy (e.g. facial thinning, decreased adipose tissue in the extremities) is thought to be caused by thymidine analogue NRTIs such as d4T and AZT
- Metabolic abnormalities: lipids (increased LDL, increased TGs), glucose (insulin resistance, type 2 DM), increased risk of CVD

Figure 11. Mechanism of HIV replications

Prevention of HIV Infection

- education, including harm-reduction
 - safer sexual practices: condoms for vaginal and anal sex, barriers for oral sex
 - harm reduction for IVDU: avoid sharing needles
- prevention of vertical HIV infection: treatment with ART should be initiated prior to pregnancy or as early as possible during pregnancy. The risk of vertical HIV transmission can be reduced to < 1% if maternal ART is started in a timely manner and the maternal viral load is undetectable prior to delivery.
- universal blood and body precautions for health care workers
 - post-exposure prophylaxis (PEP) after occupational (e.g. needle-stick injury) and non-occupational (e.g. consensual sex, sexual assault) exposure to HIV: 2- or 3-drug regimen initiated immediately (<72 h) after exposure and continuing for 4 wk
- recent data has demonstrated efficacy of pre-exposure prophylaxis (oral PrEP or topical microbicides) in preventing HIV
- ART associated with 96% reduction in risk of transmitting HIV to sexual partners
- screening of blood and organ donation

Types of Testing

1. Nominal/Name-Based HIV Testing

- person ordering the test knows the identity of the person being tested for HIV
- HIV test is ordered using the name of the person being tested
- person ordering the test is legally obligated to notify Public Health officials if test results are positive for HIV
- test result is recorded in the health care record of the person being tested

2. Non-Nominal/Non-Identifying HIV Testing

- similar to nominal/name-based testing on all points except:
- HIV test is ordered using a code or the initials of the person being tested

3. Anonymous Testing

- available at specialized clinics
- person ordering the HIV test does not know the identity of the person being tested
- HIV test is carried out using a unique non-identifying code that only the person being tested for HIV knows
- test results are not recorded on the health care record of the person being tested
- patient identification and notification of Public Health required to gain access to ART

Early identification of HIV is essential for patients to receive the maximal benefit from ART

HIV Pre- and Post-Test Counselling

- a diagnosis of HIV can be overwhelming and is often associated with stigma and discrimination
- consider pre- and post-test counselling, regardless of the results
- goals include: assessing risk, making informed decision to be tested, education to protect themselves and others from virus exposure, where to go for more information and support
- HIV+ patients should be connected with local support services

Fungal Infections

Skin and Subcutaneous Infections

Superficial Fungal Infections

- see [Dermatology, D25](#)

Dermatophytes

- see [Dermatology, D26](#)

Subcutaneous Fungal Infection

Etiology

- subcutaneous inoculation by fungi that naturally reside in the soil, including *Sporothrix schenckii*, which usually occurs in gardeners injured by a rose thorn or splinter

Clinical Presentation

- causes subcutaneous nodules at the point of entry, may develop into an ulcer
- fungi may migrate up lymphatic vessels creating nodules along the way – “nodular lymphangitis”

Treatment

- oral azole (e.g. itraconazole)
- IV amphotericin B for severe or disseminated infection

Endemic Mycoses

Etiology

- fungal infection that occurs through the inhalation of spores (from soil, bird droppings, vegetation) or inoculation injury
- thermally dimorphic organisms: mould in cold temperature (e.g. soil) and yeast at higher temperature (e.g. tissue)
- in North America, the three major endemic mycoses are: histoplasmosis, blastomycosis, and coccidioidomycosis

Histoplasmosis is commonly associated with exposure to chicken coops, bird roosts, and bat caves

Clinical Presentation

- may be asymptomatic
- all can cause pneumonia and may disseminate hematogenously
- may reactivate or disseminate during immunocompromised states

Treatment

- common to all endemic mycoses
 - oral azole (e.g. itraconazole for mild-moderate local infection)
 - IV amphotericin B for systemic infection

Table 25. Endemic Mycoses

Disease	Endemic Region	Clinical Features	Investigations
<i>Histoplasma capsulatum</i>	Ohio and Mississippi River valleys in central USA, Ontario, Quebec; widespread	Asymptomatic (in most people) Primary pulmonary <ul style="list-style-type: none"> • Fever, cough, chest pain, H/A, myalgia, anorexia • CXR (acute): pulmonary infiltrates ± hilar lymphadenopathy • CXR (chronic): pulmonary infiltrates, cavitory disease Disseminated (rare) <ul style="list-style-type: none"> • Occurs primarily in immunocompromised patients • Spread to bone marrow (pancytopenia), GI tract (ulcers), lymph nodes (lymphadenitis), skin, liver, adrenals, CNS 	Fungal culture, fungal stain Antigen detection (urine and serum) Serology
<i>Blastomyces dermatitidis</i>	States east of Mississippi River, Northern Ontario and along the Great Lakes	May be asymptomatic Primary: acute or chronic pneumonia <ul style="list-style-type: none"> • Fever, cough, chest pain, chills, night sweats, weight loss • CXR (acute): lobar or segmental pneumonia • CXR (chronic): lobar infiltrates, fibronodular interstitial disease Disseminated <ul style="list-style-type: none"> • Spread to skin (verruccous lesions that mimic skin cancer, ulcers, subcutaneous nodules), bones (osteomyelitis, osteolytic lesions), GU tract (prostatitis, epididymitis) 	Sputum smear and culture Direct examination of clinical specimens for characteristic broad-based budding yeast (sputum, tissue, purulent material)
<i>Coccidioides immitis</i>	Deserts in southwest USA, northwest Mexico	Primary <ul style="list-style-type: none"> • "Valley fever": subacute fever, chills, cough, chest pain, sore throat, fatigue that lasts for weeks to months • Can develop hypersensitivity with arthralgias, erythema nodosum Disseminated <ul style="list-style-type: none"> • Rare spread to skin (ulcers), joints (synovitis), bones (lytic lesions), meninges (meningitis) • Common opportunistic infection in patients with HIV 	Sputum culture Direct examination of clinical specimens for characteristic yeast (sputum, tissue, purulent material)

Opportunistic Fungi***Pneumocystis jiroveci* (formerly *P. carinii*)
Pneumonia: PJP or PCP****Etiology**

- respiratory exposure to a unicellular fungi (previously classified as a protozoa)
- rarely transmitted from person to person
- without prophylaxis, HIV patients with a CD4 count <200 cells/mm³ have an 80% lifetime risk of PJP

Clinical Presentation

- symptoms of pneumonia: fever, nonproductive cough, progressive dyspnea
- classic CXR
- most clinical disease is due to reactivation of latent infection or reinfection by a different genotype in immunocompromised patients (steroid use, HIV)

Investigations

- demonstration of organism in induced sputum, bronchoalveolar lavage, or endotracheal aspirate (if intubated)

Treatment and Prevention

- oxygen to keep SaO₂ >90%
- antimicrobial options
 - TMP/SMX (PO or IV)
 - dapsone and TMP
 - clindamycin and primaquine
 - pentamidine (IV)
 - atovaquone
- corticosteroids used as adjuvant therapy in those with severe hypoxia (pO₂ <70 mmHg or A-a gradient O₂ >35 mmHg)
- prophylactic TMP/SMX for those at high risk of infection (HIV patients when CD4 <200 cells/mm³ or non-HIV immunocompromised patients under specific conditions).

**CXR in *P. jiroveci***

- Bilateral, diffuse opacities
- CXR may be normal (20-30% cases)
- CT shows cysts (hence the name *Pneumo*"cystis") but almost never pleural effusions

***Cryptococcus* spp.**

Etiology

- inhalation of airborne encapsulated yeast from soil contaminated with pigeon droppings (*C. neoformans*) or certain tree species such as Eucalyptus or Douglas fir (*C. gatti*)
- *C. neoformans* tends to affect immunocompromised hosts vs. *C. gatti* which tends to affect immunocompetent hosts

Clinical Presentation

- asymptomatic
- pulmonary
 - usually asymptomatic or self-limited pneumonitis
 - only 2% of HIV+ patients present with pulmonary symptoms including productive cough, chest tightness, and fever
- disseminated
 - frequently disseminates in HIV+ population
 - CNS: meningitis (leading cause of meningitis in patients with HIV)
 - skin: umbilicated papules that resemble large lesions of *Molluscum contagiosum*
 - other: bone, lymph nodes, bone marrow, soft tissues, eyes

Investigations

- serum cryptococcal antigen
- CSF for meningitis: India-ink stain, cryptococcal antigen test, culture to confirm

Treatment

- in patients with HIV who have cryptococcal meningitis or severe pulmonary disease:
 - amphotericin B (+ flucytosine) is used in the first 2 wk for induction therapy; limited duration due to side effects
 - switch to fluconazole for at least 8 wk as consolidation therapy, then continue at lower dose for prolonged maintenance

C. gatti sees limited geographical distribution including Vancouver Island, Northern Australia, and Papua New Guinea

India-ink sensitivity for *Cryptococcus* is only 50% (higher in HIV patients); now replaced by cryptococcal antigen test in most laboratories

Candida albicans

Etiology

- overgrowth of *C. albicans* (normally found as part of the microbiome of the skin, mouth, vagina and GI tract)
- risk factors for overgrowth:
 - immunocompromised state (DM, corticosteroids)
 - ICU patients (broad-spectrum antibiotic use, central venous catheters, TPN)
 - obesity → maceration and moisture in intertriginous areas, pannus, under breasts

Clinical Presentation

- mucocutaneous
 - oral thrush, esophagitis (chest pain, odynophagia), vulvovaginitis (see [Gynecology, GY26](#)), balanitis, cutaneous (diaper rash, skin folds, folliculitis), chronic mucocutaneous
 - small satellite lesions beyond the margin of the rash
- invasive
 - candidemia, endophthalmitis, endocarditis, UTI (upper tract), hepatosplenic disease

Treatment

- thrush: nystatin suspension or pastilles for mild disease, fluconazole for severe disease
- vulvovaginal candidiasis: topical agents (imidazole or nystatin), oral fluconazole for recurrent disease
- cutaneous infection: topical imidazole
- opportunistic infections in HIV, other systemic infections: fluconazole or echinocandin
- chronic mucocutaneous: azoles

Aspergillus spp.

Etiology

- infection with *Aspergillus* fungi (*A. fumigatus*, *A. flavus*) which is found ubiquitously in the air and the environment
- Aspergillus* produces a toxin called aflatoxin that contaminates nuts, grains, and rice

Clinical Presentation

- allergic bronchopulmonary aspergillosis (ABPA)
 - IgE-mediated asthma-type reaction with dyspnea, high fever, and transient pulmonary infiltrates
 - occurs more frequently in patients with asthma and allergies
- aspergilloma (fungus ball)
 - ball of hyphae in a preexisting lung cavity
 - symptoms range from asymptomatic to massive hemoptysis
 - CXR: round opacity surrounded by a thin lucent rim of air, often in upper lobes ("air crescent" sign)
- invasive aspergillosis
 - associated with prolonged and persistent neutropenia or transplantation
 - pneumonia – most common
 - may disseminate to other organs: brain, skin
 - severe symptoms with fever, cough, dyspnea, cavitation; fatal if not treated early and aggressively
 - CXR: local or diffuse infiltrates ± pulmonary infarction, pulmonary nodules with surrounding ground glass ("halo" sign)
- mycotoxicosis
 - aflatoxin produced by *A. flavus* (nuts, grains, rice)
 - results in liver hemorrhage, necrosis, and hepatocellular carcinoma formation

Treatment Options

- for invasive aspergillosis: voriconazole or amphotericin B
- surgical resection for aspergilloma
- corticosteroids ± itraconazole for Allergic Bronchopulmonary Aspergillosis

Parasitic Infections

Protozoa – Intestinal/Genitourinary Infections

Entamoeba histolytica (Amoebiasis)

Etiology

- infection with *E. histolytica* occurs when the cysts are transmitted via the oral-fecal route in areas of poor sanitation that have been contaminated by other infected humans
- seen in migrants, travellers, institutionalized individuals, Aboriginal Canadians, MSM

Clinical Presentation

- asymptomatic carriers
- amoebic dysentery
 - abdominal pain, cramping, colitis, dysentery, low grade fever with bloody diarrhea secondary to local tissue destruction and ulceration of large intestine
- amoebic abscesses (liver abscesses, [see General Surgery, GS43](#))
 - most common in liver (hematologic spread); presents with RUQ pain, weight loss, fever, hepatomegaly
 - can also occur in lungs and brain

Investigations

- serology, fecal/serum antigen testing, stool exam (for cysts and trophozoites), colon biopsy
- E. histolytica* indistinguishable microscopically from the non-pathogen *E. dispar* (distinguish by specific stool antigen detection)

Treatment and Prevention

- metronidazole
- for invasive disease or cyst elimination: follow with iodoquinol or paromomycin
- aspiration of hepatic abscess if risk of cyst rupture, poor response to medical therapy, or diagnostic uncertainty
- asymptomatic cyst shedding: iodoquinol or paromomycin alone
- good personal hygiene, purification of water supply by boiling, filtration (not chlorination)

Figure 12. *Entamoeba* life cycle

Giardia lamblia

Etiology

- infection with *G. lamblia* occurs via the fecal-oral route with the ingestion of cysts from water/food contaminated by infected humans and other mammals (especially in the Rockies)
- risk factors: travel, camping, institutions, day care centres, MSM

Clinical Presentation

- giardiasis (“beaver fever”)
 - symptoms vary from asymptomatic to self-limited mild watery diarrhea to malabsorption syndrome (chronic giardiasis where the parasite coats the small intestine and thus prevents fat absorption)
 - nausea, malaise, abdominal cramps, bloating, flatulence, fatigue, weight loss, steatorrhea
 - no hematochezia (no invasion into intestinal wall), no mucous in stool

Investigations

- multiple stool samples (daily x 3 d) for microscopy, stool antigen used occasionally
- occasionally small bowel aspirate or biopsy

Treatment and Prevention

- metronidazole; nitazoxanide if symptomatic
- good personal hygiene and sanitation, water purification (iodine better than chlorination), outbreak investigation

Trichomonas vaginalis

Etiology

- infection with *T. vaginalis* occurs via sexual contact

Clinical Presentation

- often asymptomatic (10-50%), especially males (occasionally urethritis, prostatitis)
 - Trichomonas* vaginitis (see [Gynecology, GY27](#))
- vaginal discharge (profuse, malodorous, yellow-green or grey, frothy), pruritus, dysuria, dyspareunia

Investigations

- wet mount (motile parasites), antigen detection, culture
- urine PCR to detect in males

Treatment

- metronidazole for patient and partner(s)

***Cryptosporidium* spp.**

Etiology

- infection with *Cryptosporidium* spp. via the fecal-oral route occurs with the ingestion of cysts from water contaminated by infected humans and other animals (including cows)
- risk factors: summer and fall, young children (day care), MSM, contact with farm animals, immunodeficiency

Clinical Presentation

- range from self-limited watery diarrhea (immunocompetent) to chronic, severe, non-bloody diarrhea with N/V, abdominal pain, and anorexia resulting in weight loss and death (immunocompromised)

Investigations

- modified acid-fast stain of stool specimen, microscopic identification of oocysts in stool or tissue, stool antigen detection by direct fluorescent antibody

Treatment and Prevention

- supportive care
- in HIV+ patients, (re)initiate ART and try to increase their CD4 count to >100; if fails, try nitazoxanide
- good personal hygiene, water filtration

Trichomonas causes 25% of vaginitis

Blood and Tissue Infections

Plasmodium spp. (Malaria)

Etiology

- transmission of *Plasmodium* spp. (*P. falciparum*, *P. vivax*, *P. ovale*, *P. malariae*, *P. knowlesi*) primarily occurs during the blood meal of a night biting female *Anopheles* mosquito
- sporozoites injected during the blood meal then infect human liver cells, where they multiply and are released as merozoites; merozoites infect RBCs and cause disease
- infection with malaria parasites can also occur via vertical transmission (rare) or blood transfusion
- occurs in tropical/subtropical regions (sub-Saharan Africa, Oceania, South Asia, Central America, Southeast Asia, South America)

Clinical Presentation

- flu-like prodrome
- paroxysms of high spiking fever and shaking chills (due to synchronous systemic lysis of RBCs) (lasts several hours)
 - P. vivax* and *P. ovale*: chills and fever x48 h but can be variable
 - P. malariae*: chills and fever x72 h but can be variable
 - P. falciparum*: less predictable fever interval, can be highly variable
- abdominal pain, diarrhea, myalgia, H/A, and cough
- hepatosplenomegaly and thrombocytopenia without leukocytosis
- >90% of patients infected with *P. falciparum* are ill within 30 d
- relapsing malarial attacks may occur after many months due to the reactivation (entering the erythrocytic cycle) of dormant liver hypnozoites of either *P. ovale* or *P. vivax*
- complications:
 - P. falciparum* (most common and most lethal): CNS involvement (cerebral malaria = seizures and coma), severe anemia, acute kidney injury, ARDS, primarily responsible for fatal disease
 - P. knowlesi*, and rarely *P. vivax*, can be fatal

Investigations

- microscopy: blood smear q12-24h (x3) to rule out infection
 - thick smear (Giemsa stain) for presence of organisms
 - thin smear (Giemsa stain) for species identification and quantification of parasites
- rapid antigen detection tests

Treatment and Prevention

- P. vivax*, *P. ovale*: chloroquine (and primaquine to eradicate liver forms)
- P. vivax*, chloroquine resistant: atovaquone/proguanil + primaquine or quinine and doxycycline + primaquine
- P. malariae*, *P. knowlesi*: chloroquine
- P. falciparum*: most areas of the world show chloroquine resistance – check local resistance patterns
 - artemisinin combination therapy (e.g. artesunate + doxycycline or clindamycin or atovaquone/proguanil)
 - atovaquone/proguanil combination (Malarone®)
 - quinine + doxycycline or clindamycin
 - mefloquine and artemisinin resistance increasing in southeast Asia (check local resistance)
- prevention with antimalarial prophylaxis, covering exposed skin, bed nets, insect repellent

Trypanosoma cruzi

Etiology

- found in Mexico, South America, and Central America
- transmission by Reduviid insect vector (“Kissing Bug”), which defecates on skin and trypomastigotes in the stool are rubbed into bite site by host
- also transmitted via placental transfer, organ donation, blood transfusion, and ingestion of contaminated food containing Reduviid insects (especially cane juice)

Clinical Presentation

- American trypanosomiasis (Chagas disease)
 - acute: usually asymptomatic, local swelling at site of inoculation (“Romana’s sign”; usually around one eye) with variable fever, lymphadenopathy, cardiomegaly, and hepatosplenomegaly
 - chronic indeterminate phase: asymptomatic but increasing levels of antibody in blood; most infected persons (60-70%) remain in this phase, and do not go on to manifest a determinate form of Chagas disease
 - chronic determinate: leads to chronic dilated cardiomyopathy, esophagomegaly, and megacolon 10-25 yr after acute infection in 30-40% of infected individuals

Malaria is the most common fatal infectious disease worldwide

Figure 13. Life cycle of *Plasmodium* spp.

Drugs for Preventing Malaria in Travellers

Cochrane DB Syst Rev 2009;CD006491

Study: Cochrane Systematic Review. 8 RCTs.

Population: 4,240 non-immune adults and children traveling to regions with *P. falciparum* resistance to chloroquine.

Intervention: Atovaquone-proguanil, doxycycline, mefloquine, chloroquine-proguanil, or primaquine used for malaria prophylaxis.

Outcome: Efficacy, safety, and tolerability.

Results: Atovaquone-proguanil and doxycycline had similar adverse events. Atovaquone-proguanil had fewer overall (RR 0.72), GI (RR 0.54), and neuropsychiatric events (RR 0.49) than mefloquine. Doxycycline also had fewer neuropsychiatric events than mefloquine (RR 0.84).

Conclusion: Atovaquone-proguanil or doxycycline as prophylaxis against malaria is best tolerated in terms of adverse effects and mefloquine is associated with adverse neuropsychiatric outcomes.

Investigations

- wet prep and Giemsa stain of thick and thin blood smear, serology, PCR

Treatment and Prevention

- acute: nifurtimox or benznidazole
- indeterminate: increasing trend to treat as acute infection for children and adults under age 50 years
- chronic determinate: symptomatic therapy, surgery as necessary including heart transplant, esophagectomy, and colectomy; there may be a benefit to antiparasitic treatment
- insect control, bed nets

Toxoplasma gondii

Etiology

- infection with *T. gondii* occurs through exposure to cat feces (oocysts), ingestion of undercooked meat (tissue cysts), vertical transmission, organ transplantation, gardening without gloves (cat oocyst exposure), whole blood transfusions

Clinical Presentation

- congenital
 - result of acute primary infection of mother during pregnancy (see [Obstetrics, OB29](#), TORCH infection)
 - stillbirth (rare), chorioretinitis, blindness, seizures, severe developmental delay, microcephaly
 - initially asymptomatic infant may develop reactivation of chorioretinitis as adolescent or adult
 - blurred vision, scotoma, ocular pain, photophobia, epiphora, hearing loss, developmental delay
- acquired
 - usually asymptomatic or mononucleosis-like syndrome in immunocompetent patient
 - infection remains latent for life unless reactivation due to immunosuppression
- immunocompromised (most commonly AIDS with CD4 <200)
 - encephalitis with focal CNS lesions seen as single or multiple ring-enhancing masses on CT (H/A and focal neurological signs)
 - lymph node, liver, and spleen enlargement and pneumonitis
 - chorioretinitis

Investigations

- serology, CSF Wright-Giemsa stain, antigen or DNA detection (PCR); pathology provides definitive diagnosis
- immunocompromised patients: consider CT scan (ring-enhancing lesion in cortex or deep nuclei) and ophthalmologic examination
- negative serology in many AIDS patients (false negative due to decreased lymphocyte population)

Treatment and Prevention

- no treatment if immunocompetent, not pregnant, no severe organ damage
- pregnancy: spiramycin to prevent transplacental transmission or pyrimethamine + sulfadiazine (add folinic acid), avoid undercooked meat and refrain from emptying cat litter boxes
- HIV: pyrimethamine + sulfadiazine (see [Prophylaxis, ID30](#))
- eye disease, meningitis: corticosteroids
- proper hand hygiene, cook meat thoroughly to proper temperature

1/3 of Ontario's population is infected with *Toxoplasma gondii*

Classic Triad of Congenital Toxoplasmosis

- Chorioretinitis
- Hydrocephalus
- Intracranial calcifications

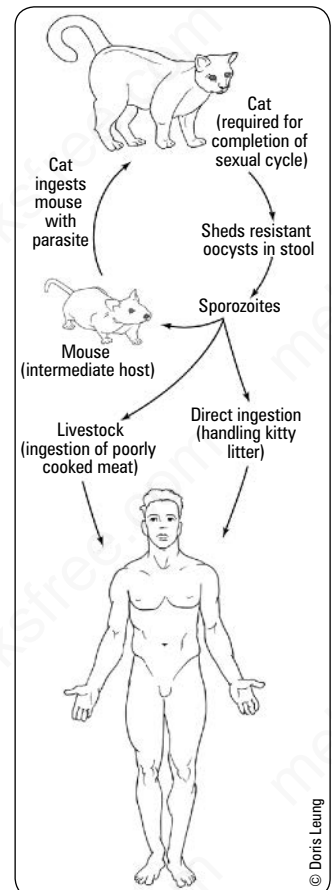

Figure 14. Life cycle of *Toxoplasma gondii*

Helminths

Roundworms – Nematodes

Table 26. Nematodes (Roundworms)

Nematode	Epidemiology	Transmission	Medical Importance	Treatment
<i>Ascaris lumbricoides</i>	Tropics	Human feces, ingestion of contaminated food or water containing eggs	Abdominal pain and intestinal obstruction from high worm burden Cough, dyspnea, pulmonary infiltrates from larval migration through lungs (Löfller's syndrome)	Mebendazole OR albendazole OR pyrantel pamoate
<i>Trichuris trichiura</i> (whipworm)	Tropics	Ingestion of eggs in soil	Diarrhea (\pm mucous, blood), abdominal pain, rectal prolapse, stunted growth	Mebendazole OR albendazole
<i>Onchocerca volvulus</i>	Africa, Latin America	Blackfly bite	River blindness (onchocerciasis), dermatitis	Ivermectin + doxycycline
<i>Wuchereria bancrofti</i>	Tropics	Mosquito bite	Damage to lymphatics resulting in lymphadenopathy, lymphedema, and elephantiasis Tropical pulmonary eosinophilia	Diethylcarbamazine + doxycycline
<i>Loa Loa</i>	Central Africa	Deer fly bite	Subcutaneous migration of worm, hyperresponsiveness in travellers	Diethylcarbamazine
<i>Enterobius vermicularis</i> (Pinworm)	Worldwide	Human host: fecal-oral self-inoculation and fomite person-to-person transfer Adult worms live in cecum and deposit eggs in peri-anal skin	Asymptomatic carriers or severe nocturnal peri-anal itching (pruritus ani) Occasional vaginitis, ectopic migration to appendix or other pelvic organs Abdominal pain, N/V with high worm burden	Sticky tape test: eggs adhere to tape applied to perianal skin (need 5-7 tests to rule out) Examination of perianal skin at night may reveal adult worms Usually no eosinophilia as no tissue invasion Mebendazole, albendazole, pyrantel in pregnancy Change underwear, bathe in morning, pajamas to bed, wash hands, trim fingernails Treat all family members simultaneously Reinfection common
<i>Strongyloides stercoralis</i> (Threadworm)	Subtropical, tropical, and temperate (including southern US)	Fecal contamination of soil: transmission via unbroken skin, walking barefoot Autoinfection: penetration of larvae through GI mucosa or perianal skin Adult worms live in mucosa of small intestine	One of few worms able to multiply in human host Mostly asymptomatic infection or can have pruritic dermatitis at site of larval penetration Transient pulmonary symptoms during pulmonary migration of larvae (eosinophilic pneumonitis = Löfller's syndrome) Abdominal pain, diarrhea, pruritus ani, larva currens (itchy rash) Hyperinfection: occasional fatal cases caused by massive auto-infection in immunocompromised host; immunoablative therapy, including high-dose corticosteroids, is the most common risk factor for disseminated infection	Ivermectin (OR Albendazole)

Figure 15. Life cycle of *Enterobius*

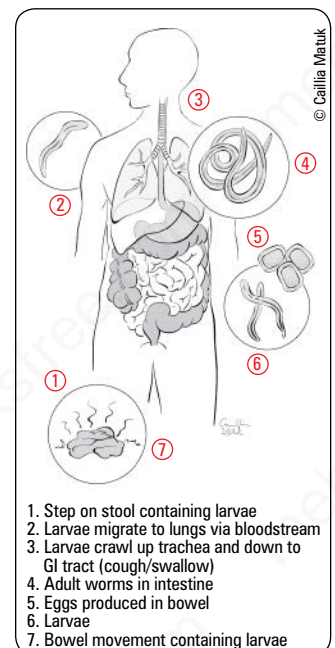

Figure 16. Life cycle of *Strongyloides*

Flatworms

Cestodes/Trematodes

Table 27. Cestodes/Trematodes (Flatworms)

	Epidemiology	Transmission	Medical Importance	Treatment
CESTODES				
<i>Taenia solium</i>	Developing countries	Undercooked pork (larvae), human feces (eggs)	Taeniasis: mild abdominal symptoms Cysticercosis: mass lesions in CNS, eyes, skin, seizures	Corticosteroids + albendazole for cysticercosis Antiepileptics if seizures Praziquantel for adult tapeworm in gut (taeniasis)
<i>Taenia saginata</i>	Developing countries	Undercooked beef (larvae)	Mild GI symptoms	Praziquantel
<i>Diphyllobothrium latum</i>	Europe, North America, Asia	Raw fish	B12 deficiency leading to macrocytic anemia and posterior column deficits	Praziquantel
<i>Echinococcus granulosus</i>	Rural areas, Sheep-raising countries	Dog feces (eggs)	Liver/lung cysts (enlarge between 1-20 yr; may cause mass effect or rupture) Risk of anaphylaxis if cystic fluid released during surgical evacuation	Albendazole ± praziquantel alone Surgery + perioperative albendazole Percutaneous aspiration + perioperative albendazole
TREMATODES				
<i>Clonorchis sinensis</i>	Japan, Taiwan, China, SE Asia	Raw fish	Exists in bile ducts, causes inflammation and sometimes cholangiocarcinoma	Praziquantel
<i>Schistosoma</i> spp.	Africa, SE Asia, focal in Western Hemisphere	Fresh water exposure	Chronic sequelae secondary to long-term infection (e.g. chronic liver disease, SCC of the bladder)	Praziquantel

Schistosoma spp.

Etiology

- infection with *Schistosoma* spp. (*S. mansoni*, *S. hematobium*, *S. japonicum*) occurs following penetration of unbroken skin by their larvae (cercariae) which are found in infested fresh water
- adult worms live in terminal venules of bladder/bowel passing eggs into urine/stool
- eggs must reach fresh water to hatch where they infect an intermediate host (snails) which then release cercariae into the water
- schistosomes cannot multiply in or pass between humans
- more common in individuals from sub-Saharan Africa, South America, Asia, Caribbean, Eastern Mediterranean/North Africa

Clinical Presentation

- most asymptomatic; symptoms seen in travellers (nonimmune)
- swimmer's itch: pruritic skin rash at site of penetration (cercarial dermatitis)
- acute schistosomiasis (Katayama fever): hypersensitivity to migrating parasites (4-8 wk after infection)
 - fever, hives, H/A, weight loss, cough, abdominal pain, chronic diarrhea, high-grade eosinophilia
- chronic schistosomiasis (can persist for years):
 - S. mansoni*, *S. japonicum*
 - worms in mesenteric vein, eggs in portal tracts of liver and bowel
 - heavy infections: intestinal polyps, portal and pulmonary HTN, splenomegaly (2° to portal HTN), hepatomegaly
 - S. hematobium*
 - worms in vesical plexus, eggs in distal ureter and bladder induce granulomas and fibrosis
 - hematuria and obstructive uropathy; associated with squamous cell bladder cancer
 - neurologic complications: spinal cord neuroschistosomiasis (transverse myelitis), cerebral or cerebellar neuroschistosomiasis (increased ICP, focal CNS signs, seizures)
 - pulmonary complications: granulomatous pulmonary endarteritis, pulmonary HTN, cor pulmonale; especially in patients with hepatosplenic involvement

Investigations

- serology (high sensitivity and specificity), CBC (eosinophilia, anemia, thrombocytopenia)
- S. mansoni*, *S. japonicum*: eggs in stool, liver U/S shows fibrosis, rectal biopsy
- S. hematobium*: bladder biopsy, eggs in urine and occasionally stool, kidney and bladder U/S

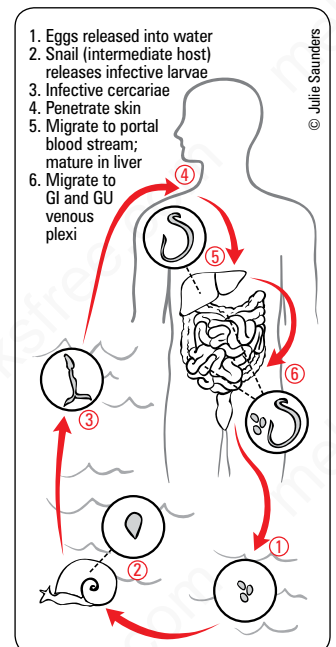

Figure 17. Life cycle of *Schistosoma*

Treatment and Prevention

- praziquantel
- add glucocorticoid if acute schistosomiasis or neurologic complications develop
- proper disposal of human fecal waste, molluscicide (pesticide against molluscs), avoidance of infested fresh water while traveling

For up to date information on geographic and seasonal patterns of disease and travel advisories, check the website for the United States Centers for Disease Control and Prevention (www.cdc.gov/travel) or Foreign Affairs Canada (travel.gc.ca)

Ectoparasites

- scabies, lice
- see [Dermatology, D26](#)

Travel Medicine

General Travel Precautions

- vector-borne: long sleeves, long pants, hats, repellents (containing permethrin) applied to clothes, belongings, and bed nets, and skin repellents (such as DEET) applied to exposed skin
- food/water: avoid eating raw meats/seafood, uncooked vegetables, and milk/dairy products; drink only bottled beverages, chlorinated water, boiled water
- recreation: caution when swimming in schistosomiasis-endemic regions (Lake Malawi), fresh water rafting/kayaking, beaches that may contain human/animal waste products, near storm drains, after heavy rainfalls
- prophylaxis: malaria (chloroquine, mefloquine, atovaquone + proguanil, doxycycline), traveller's diarrhea (bismuth salicylate)
- standard vaccines up to date (hepatitis B, MMR, tetanus/diphtheria, varicella, pertussis, polio, influenza)
- travel vaccines: hepatitis A/B, Japanese encephalitis, typhoid fever, yellow fever, rabies, ETEC, cholera
- sexually transmitted and blood-borne infections: safe sex practices, avoidance of percutaneous injury through razors, tattoos, piercings

Infectious Diseases to Consider

- vector borne: malaria, dengue fever, Chikungunya, yellow fever, spotted fever rickettsioses, West Nile virus, trypanosomiasis, Japanese encephalitis, tick-borne encephalitis, leishmaniasis, Zika virus
- sexually transmitted: HIV, HBV, acute HSV, syphilis, usual STIs
- zoonotic: rabies, hantavirus, tularemia, Q fever, anthrax, brucellosis
- airborne: TB
- food/water: HAV, HEV, brucellosis, typhoid, paratyphoid, amoebiasis, dysentery, traveller's diarrhea, cholera, *Campylobacter* spp.
- soil/water: schistosomiasis, strongyloidiasis, leptospirosis, cutaneous larva migrans, histoplasmosis, paracoccidiodomycosis

Fever in the Returned Traveller

Etiology

- commonly identified causes of fever in returning traveller
 - parasitic: malaria (20-30%)
 - viral: non-specific mononucleosis-like syndrome (4-25%), dengue (5%), viral hepatitis (3%)
 - bacterial: typhoid from *Salmonella* (2-7%), rickettsioses (3%)
 - diverse group of causative pathogens: traveller's diarrhea (10-20%), RTI (10-15%), UTI/STI (2-3%)
- febrile illness in travellers can be caused by routine infections that are common in non-travellers (e.g. URTI, UTI)
- less commonly, fever can be due to non-infectious causes (e.g. DVT, PE)

History

- pre-travel preparation
- travel itinerary: when, where, why, what, who, how?
 - dates of travel (determine incubation period)
 - season of travel: wet or dry
 - destination: country, region (urban or rural), environment (jungle, desert, etc.)
 - purpose of trip
- persons visiting friends and family more likely to be exposed to local population and pathogens
 - style of travel: lodgings, camping, adventure travelling
 - local population: sick contacts
 - transportation: use of animals

Important Exposures

Insect Bites

Mosquito	<ul style="list-style-type: none"> • <i>Plasmodium</i> spp. (Malaria) • Dengue • Chikungunya • Lymphatic filariasis (Elephantiasis) • West Nile Encephalitis • Yellow Fever • Japanese Encephalitis
Tick	<ul style="list-style-type: none"> • <i>Borrelia burgdorferi</i> (Lyme Disease) • <i>Rickettsia rickettsii</i> (Rocky Mountain Spotted Fever)
Fly	<ul style="list-style-type: none"> • <i>Trypanosoma brucei</i> spp. (African sleeping sickness) • <i>Leishmania</i> spp. (Leishmaniasis) • <i>Bartonella bacilliformis</i> (Bartonellosis)
Flea	<ul style="list-style-type: none"> • <i>Yersinia</i> (Plague) • <i>Tunga penetrans</i> (Tungiasis)

Mammal Bites

Dog/Cat	<ul style="list-style-type: none"> • Rabies, <i>Pasteurella</i>, anaerobes, <i>Streptococcus</i>, <i>S. aureus</i>
Human	<ul style="list-style-type: none"> • <i>Streptococcus</i>, <i>S. aureus</i>, oral anaerobes, <i>Eikenella</i>

Oral Exposures

Unpasteurized Milk	<ul style="list-style-type: none"> • <i>Brucella</i> spp., non-tuberculous <i>Mycobacteria</i>, <i>Salmonella</i>, <i>E. coli</i>, <i>Listeria</i>
Undercooked Meat/Fish	<ul style="list-style-type: none"> • Enteric bacteria, helminths, protozoa
Water	<ul style="list-style-type: none"> • Hepatitis A/E, Norwalk, cholera, <i>Salmonella</i>, <i>Shigella</i>, <i>Giardia</i>, poliovirus, <i>Cryptosporidium</i>, <i>Cyclospora</i>

Environmental Exposures

Fresh Water	<ul style="list-style-type: none"> • <i>Leptospira</i> spp., schistosomes, <i>Acanthamoeba</i>, <i>Naegleria fowleri</i>
Soil	<ul style="list-style-type: none"> • Hookworms, <i>Toxocara</i> spp. (visceral larva migrans), <i>Leptospira interrogans</i> (leptospirosis)

Adapted with permission from *Lancet* 2003;361:1459-69

- exposure history
 - street foods, untreated water: increased risk of traveller's diarrhea, enteric fever
 - uncooked meat/unpasteurized dairy: increased risk of parasitic infection
 - body fluids (sexual contacts, tattoos, piercings, IVDU, other injections)
 - increased risk of HBV, HCV, HIV, GC, *C. trachomatis*, syphilis
 - animal/insect bites: increased risk of malaria, dengue, rickettsioses, rabies
- fever pattern
- incubation period: use the earliest and latest possible dates of exposure to narrow the differential diagnosis and exclude serious infections
 - <21 d: consider malaria, typhoid fever, dengue fever, chikungunya, rickettsioses; exclude HBV, TB
 - >21 d: consider malaria, TB, typhoid fever; exclude dengue fever, chikungunya, traveller's diarrhea, rickettsioses
- body systems affected: GI, respiratory, CNS, skin

Fever in traveller from malaria endemic area is malaria until proven otherwise

Investigations

- all travellers with fever should undergo the following tests
 - blood work: CBC and differential, liver enzymes, electrolytes, creatinine, thick and thin blood smears x3 (for malaria), blood C&S
 - urine: urinalysis, urine C&S if dysuria or other localizing signs
- special tests based on symptoms, exposure history, and geography
 - stool: C&S, O&P
 - CXR
 - dengue serology for IgM

Table 28. Fever in the Returned Traveller

Illness	Geography/Timing	Pathogen	Incubation Period	Clinical Manifestations	Diagnosis	Treatment
Malaria	Africa India C. and S. America SE Asia Usually rural, night-biting mosquitoes	<i>Plasmodium falciparum</i> <i>Plasmodium vivax</i> <i>P. malariae</i> <i>P. ovale</i> <i>P. knowlesi</i>	7-30 d to mo or years	Fever and flu-like illness, (shaking chills, H/A, muscle aches, and fatigue) N/V and diarrhea Anemia and jaundice <i>Plasmodium falciparum</i> : (severe) kidney failure, seizures, mental confusion, prostration, coma, death, respiratory failure	Blood smear (thick and thin) x3 Rapid Diagnostic Test (with smear or PCR confirmation) Antigen detection PCR (mostly a research tool)	Artesunate (for severe disease) + malarone, doxycycline, or clindamycin Quinine sulfate + doxycycline or clindamycin Chloroquine + primaquine
Dengue	South East Asia Caribbean Usually urban, day-biting mosquitoes	Dengue viruses	3 d to 2 wk	Sudden onset of fever, H/A, retro-orbital pain, myalgias, and arthralgias Leukopenia Thrombocytopenia Hemorrhagic manifestations (rare in travellers)	Anti-dengue IgM positivity	Symptom relief: Acetaminophen (avoid using NSAIDs because of anticoagulant properties)
Typhoid (enteric fever)	Global but mostly Indian subcontinent	<i>Salmonella typhi</i> <i>Salmonella paratyphi</i>	3 to 60 d	Sustained fever 39°-40°C (103°-104°F) Abdominal pain, H/A, loss of appetite, cough, constipation	Stool, urine, or blood sample positive for <i>S. typhi</i> or <i>S. paratyphi</i>	Quinolone antibiotic (e.g. ciprofloxacin), ceftriaxone, or macrolide
Tick Typhus	Mediterranean South Africa India	<i>Rickettsia</i>	1 to 2 wk	Fever, H/A, fatigue, muscle aches, occasionally rash Eschar at site of tick bite Thrombocytopenia Elevated liver enzymes	Serology Presence of classic tick eschar	Doxycycline
TB	Global	<i>M. tuberculosis</i>	Variable	Fever, cough, hemoptysis	CXR Sputum culture and acid-fast stain	Ethambutol, isoniazid, pyrazinamide, rifampin, +/- pyridoxine (vit. B6)
Mononucleosis	Caribbean, C. and S. America	EBV or CMV	30 to 50 d	Malaise, fatigue, pharyngitis, lymphadenopathy, splenomegaly	Atypical lymphocytes on blood smear and positive heterophilic antibody (monospot) test	Acetaminophen or NSAIDs, fluids
Zika Virus Disease	Africa, SE Asia, S. America; spreading	Zika virus	Unknown, likely 3 to 12 d	Headache, malaise, muscle/joint pain, mild fever, rash, conjunctivitis	RT-PCR Serology	Rest, fluids, analgesics/antipyretics (avoid NSAIDs until Dengue ruled out), condom use, avoid pregnancy

Fever of Unknown Origin

Table 29. Classification of Fever of Unknown Origin (FUO) – Temp >38.3°C/101°F on several occasions

Classical FUO	Nosocomial FUO	Neutropenic FUO	HIV-associated FUO
Duration >3 wk	Hospitalized patient Infection not present/ incubating on admission	Neutrophil count <500/mL or is expected to fall to that level in 1-2 d	HIV infections Duration >4 wk for outpatients, >3 d for hospitalized patients
Diagnosis uncertain after 3 outpatient visits or 3 d in hospital or 1 wk of intensive ambulatory investigation	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures	Diagnosis uncertain after 3 d of investigation, including at least 2 d incubation of cultures

Etiology of Classic FUO

- infectious causes (~30%)
 - TB: extra-pulmonary (most common), miliary, pulmonary (if pre-existing disease)
 - abscess: subphrenic, liver, splenic, pancreatic, perinephric, diverticular, pelvis, psoas
 - osteomyelitis
 - bacterial endocarditis (culture negative)
 - uncommon: viral (CMV, EBV), bacterial (brucellosis, bartonellosis), fungal (histoplasmosis, cryptococcosis), parasitic (toxoplasmosis, leishmaniasis, amoebiasis, malaria)
- neoplastic causes (~20%)
 - most commonly lymphomas (especially non-Hodgkin's) and leukemias, also multiple myeloma, myelodysplastic syndrome
 - solid tumours: RCC (most common), also breast, liver (hepatoma), colon, pancreas, or liver metastases
- collagen vascular diseases (~30%)
 - SLE, RA, rheumatic fever, vasculitis (temporal arteritis, PAN), JRA, Still's disease
- miscellaneous (~20%)
 - drugs, factitious fever
 - sarcoidosis, granulomatous hepatitis, IBD
 - hereditary periodic fever syndromes (such as familial Mediterranean fever)
 - venous thromboembolic disease: PE, DVT
 - endocrine: thyroiditis, thyroid storm, adrenal insufficiency, pheochromocytoma
- unknown in 30-50% despite detailed workup

Approach to Classic FUO

- careful history: travel, environmental/occupational exposures, infectious contacts, medication history, immunizations, TB history, sexual history, past medical history, comprehensive review of systems (including symptoms that resolved before interview)
- thorough physical exam: fever pattern, rashes (skin, mucous membranes), murmurs, arthritis, lymphadenopathy, organomegaly
- initial investigations as appropriate
 - blood work: CBC and differential, electrolytes, BUN, Cr, calcium profile, LFTs, ESR, CRP, muscle enzymes, RF, ANA, serum protein electrophoresis (SPEP), blood smear
 - cultures: blood (x2 sets), urine, sputum, stool C&S, O&P, other fluids as appropriate
 - serology: HIV, monospot, CMV IgM
 - imaging: CXR, abdominal imaging
- if there are diagnostic clues from any of the above steps, proceed with directed exam, biopsies or invasive testing as required, followed by directed treatment once a diagnosis is established
- if no diagnosis with the above, consider empiric therapy vs. watchful waiting
 - without intervention: patients that remain undiagnosed despite extensive workup have good prognosis
- immunocompromised hosts have increased susceptibility to infections from pathogens that are typically low virulence, commensal, or latent
- type of immunodeficiency predicts probable spectrum of agents

Causes of Nosocomial FUO B, C, D, E

Bacterial and fungal infections of respiratory tract and surgical sites
Catheters (intravascular and urinary)
Drugs
Emboli

Drugs that may Cause Fever

- Anti-microbials (sulfonamides, penicillins, nitrofurantoin, antimalarials)
- Anti-hypertensives (hydralazine, methyl dopa)
- Anti-epileptics (barbiturate, phenytoin)
- Anti-arrhythmics (quinine, procainamide)
- Anti-inflammatories (NSAIDs)
- Anti-thrombotics (ASA)
- Anti-histamines
- Anti-thyroid

Infections in the Immunocompromised Host

Factors that Compromise the Immune System

- general: age (very young or elderly), malnutrition
- immune disease: HIV/AIDS, malignancies, asplenia (functional or anatomic), hypogammaglobulinemia, neutropenia
- DM
- iatrogenic: corticosteroids, chemotherapy, radiation treatment, anti-TNF therapy, other immunosuppressive drugs (e.g. in transplant patients)

Table 30. Types of Immunodeficiency

Type	Conditions	Vulnerable To
Cell-Mediated Immunity	HIV, Hodgkin's, hairy cell leukemia, cytotoxic drugs, SCID, DiGeorge syndrome	Latent viruses Fungi Parasites
Humoral Immunity	CLL, lymphosarcoma, multiple myeloma, nephrotic syndrome, protein-losing enteropathy, burns, sickle cell anemia, asplenia, splenectomy, selective Ig deficiencies, Wiskott-Aldrich syndrome	Encapsulated organisms (<i>S. pneumoniae</i> , <i>H. influenzae</i> , <i>N. meningitidis</i> , <i>Salmonella typhi</i> , GBS)
Neutrophil Function	Myelodysplasia, paroxysmal nocturnal hemoglobinuria, radiation, cytotoxic drug therapy, C3 or C5 deficiencies, chronic granulomatous disease	Catalase-producing organisms (<i>Staphylococcus</i> , <i>Serratia</i> , <i>Nocardia</i> , <i>Aspergillus</i>)

Febrile Neutropenia

Definition

- fever ($\geq 38.3^{\circ}\text{C}/101^{\circ}\text{F}$ or $\geq 38.0^{\circ}\text{C}/100.4^{\circ}\text{F}$ for ≥ 1 h) and one of
 - ANC < 0.5 OR
 - ANC < 1.0 but trending down to 0.5

Pathophysiology

- decreased neutrophil production
 - marrow: infection, aplastic/myelophthisic anemia, leukemia, lymphoma, myelodysplastic syndromes
 - iatrogenic: cancer chemotherapy, radiation, drugs
 - deficiencies: vitamin B₁₂, folate
- increased peripheral neutrophil destruction
 - autoimmune: Felty's syndrome, SLE, antineutrophil antibodies
 - splenic sequestration

Epidemiology/Etiology

- most common life-threatening complication of cancer therapy
- 8 cases per 1,000 cancer patients per yr in the U.S.
- causative organism identified only 1/3 of the time
- GN (especially *Pseudomonas*) historically most common
- GP more common now
- fungal superinfection if neutropenia prolonged or if concurrent antibiotic use (especially *Candida*, *Aspergillus*)

Investigations

- examine for potential sites of infection: mucositis and line infections are most common
- do NOT perform DRE; examine perianal region
- blood C&S (x2 sets), urine C&S, culture all indwelling catheter ports, \pm sputum C&S and nasopharyngeal swab for respiratory viruses
- CBC and differential, Cr, BUN, electrolytes, AST/ALT, total bilirubin

Treatment

- most hospitals have their own specific protocol; one example see Figure 18

Infections Associated with Asplenia

- *Haemophilus influenzae* type b
- *Streptococcus pneumoniae*
- *Neisseria meningitidis*
- *Salmonella*
- Babesiosis
- Malaria
- *Capnocytophaga canimorsus* (dog bite)

ANC (absolute neutrophil count) =
WBC \times (%neutrophils + %bands)

Usual signs and symptoms of infection may be diminished because neutrophils are required for a robust inflammatory response; exam and x-ray findings may be more subtle

WBC is lowest between 5-10 d after last chemotherapy cycle

Prophylaxis against FN with G-CSF (granulocyte colony-stimulating factor) and GM-CSF (granulocyte-macrophage colony-stimulating factor) decreases hospitalization without affecting mortality (indicated if risk of FN 20% or if FN has occurred in a previous chemotherapy cycle)

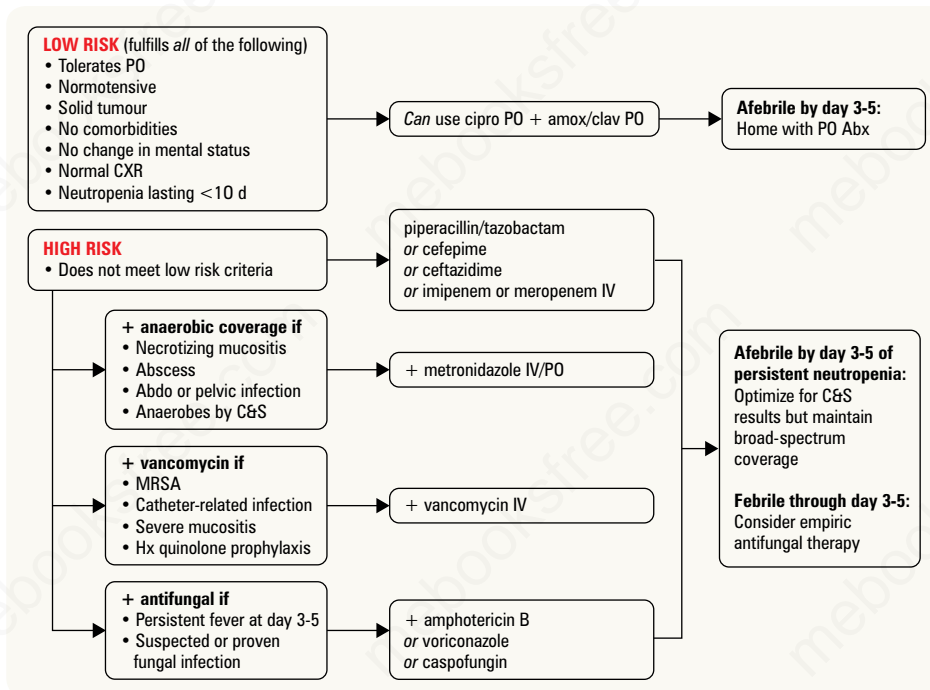

Figure 18. Example of treatment protocol for febrile neutropenia

Infections in Solid Organ Transplant Recipients

- infection is a leading cause of early morbidity/mortality in transplant recipients
- infection depends on degree of immunosuppression
- common infections <1 mo post-transplant
 - bacterial infection of wound/lines/lungs, herpetic stomatitis
- common infections >1 mo post-transplant
 - viral (especially CMV, EBV, VZV)
 - fungal (especially *Aspergillus*, *Cryptococcus*, *P. jiroveci*)
 - protozoan (especially *Toxoplasma*)
 - unusual bacterial/mycobacterial infections (especially TB, *Nocardia*, *Listeria*)

Prophylactic Vaccinations Given Before Transplant

- to all transplant patients: DTaP, pneumococcal, influenza, hepatitis A and B vaccines
- if low titre or poor documentation: MMR, polio, varicella vaccination (with booster 4-8 wk later)

Immune Reconstitution Syndrome

Definition

- a harmful inflammatory response directed against a previously acquired infection following a recovery of the immune system

Etiology

- paradoxical worsening of a successfully or partially treated opportunistic infection
- new onset response to a previously unidentified opportunistic infection
- the majority of cases are in HIV/AIDS or immunosuppressed patients starting anti-retroviral therapy or discontinuing immunosuppressive therapy; sudden recovery from an immunosuppressive state towards a pro-inflammatory state directed towards subclinical infection results in fever and inflammation
- can occur in response to multiple infections
 - *Mycobacteria* (tuberculosis, avium complex)
 - *Cryptococcus*
 - *Pneumocystis*
 - *Toxoplasma*
 - HBV and HCV
 - Herpes viruses (VZV reactivation, HSV, CMV)
 - JC virus (progressive multifocal leukoencephalopathy)
 - Molluscum contagiosum
- clinical features are dependent on the type and location of the pre-existing infection
- thought to be worse with quick increase in CD4 count and with lower pre-treatment CD4 count
- non-HIV conditions with documented IRS: solid organ transplant recipients, post-partum women, neutropenic patients, anti-TNF therapy

Epidemiology

- in HIV patients starting ART, IRS reported to affect ~10%

Investigations

- IRS is a diagnosis of exclusion
- rule out drug reaction, patient non-adherence, drug resistance

Treatment

- continue HAART therapy in HIV patients with mild-moderate symptoms, but consider discontinuation if symptoms are life-threatening or potentially irreversible
- treat underlying infection; initiate treatment for some infections prior to HAART initiation
- consider starting corticosteroids/NSAIDs to decrease inflammatory response

A Simplified Look at Antibiotics

- general overview, see [Table 31](#) for more details

1. Penicillins

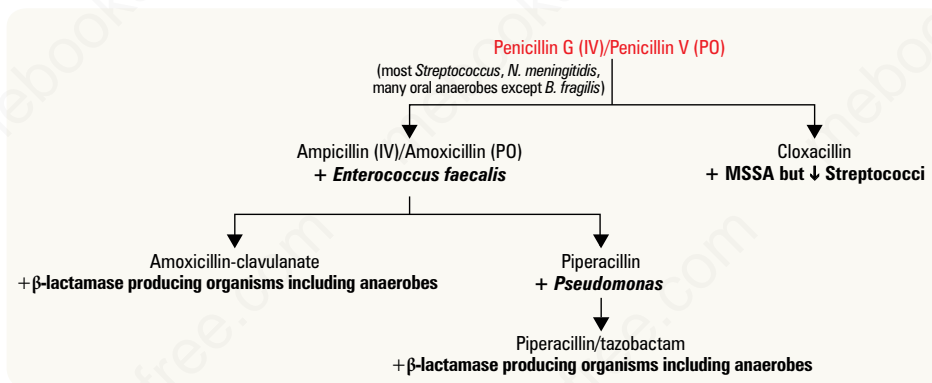

Figure 19. Penicillins

2. Cephalosporins (PO/IV)

- 1st generation: cephalexin/cefazolin (mostly GP, some GN)
- 2nd generation: cefuroxime/cefprozil (some GP and some GN, *anaerobes)
- 3rd generation: cefixime/cefotaxime, ceftriaxone (good Streptococcal coverage, mostly GN), and ceftazidime (no GP, mostly GN, Pseudomonas)
- 4th generation: --/cefepime (most GP, most GN, Pseudomonas)

3. Aminoglycosides (GN aerobic bacilli)

- gentamicin
- tobramycin
- amikacin

4. Macrolides (GP, Haemophilus, and atypical bacteria [Legionella, Chlamydophila, Mycoplasma])

- erythromycin
- clarithromycin
- azithromycin

5. Fluoroquinolones (GN – although resistance becoming a huge problem)

- ciprofloxacin (+ Pseudomonas)
- norfloxacin (for UTI only)
- respiratory fluoroquinolones (some GP, GN, “atypicals”, Legionella, Mycoplasma, Chlamydophila, Mycobacteria)
 - levofloxacin, ofloxacin
 - moxifloxacin (+ anaerobes)

6. Carbapenems (broad coverage: GP, GN, and anaerobes)

- imipenem (+ Pseudomonas)
- meropenem (+ Pseudomonas)
- ertapenem

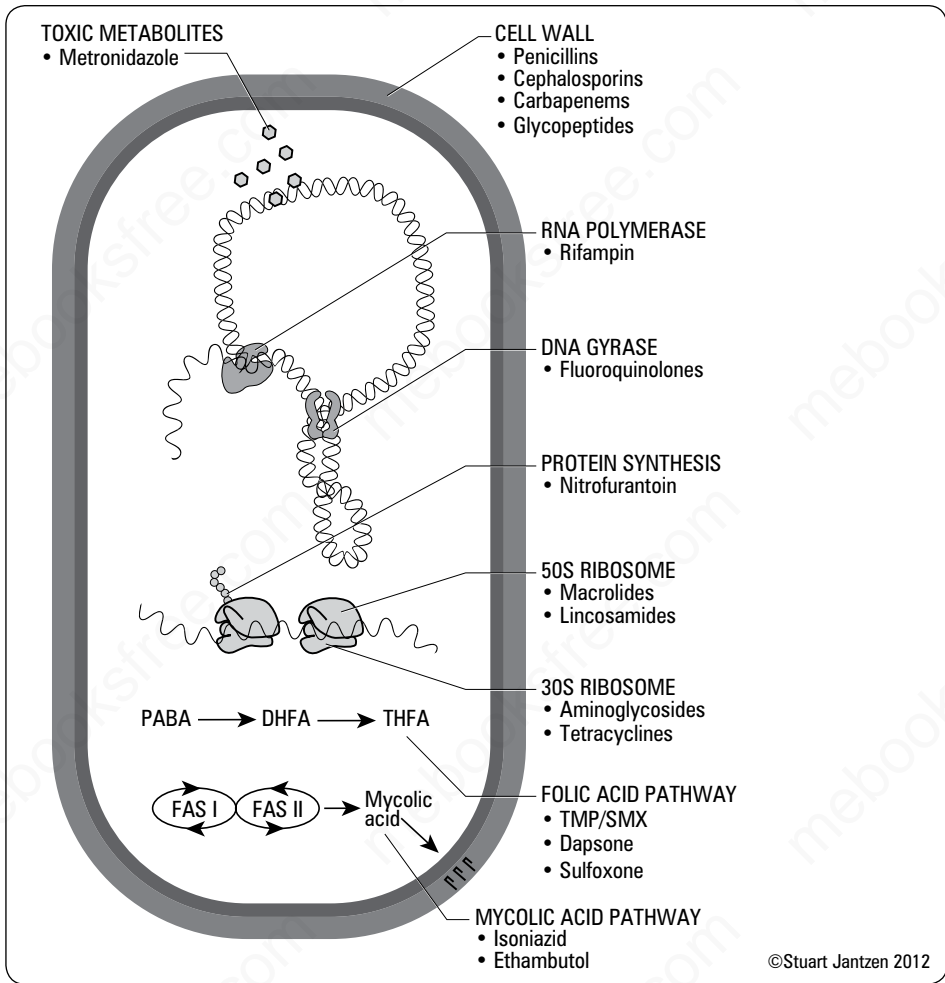

7. Others

- doxycycline/tetracycline (GP, syphilis, *Chlamydomphila*, *Rickettsia*, *Mycoplasma*)
- tigecycline (for resistant GP infections, GN, anaerobes, *Chlamydomphila*, *Rickettsia*, *Mycoplasma*)
- vancomycin (all GP and *C. difficile* – the oral form for)
- linezolid (for resistant GP infections)
- daptomycin (for resistant GP infections)
- clindamycin (most GP, GN anaerobes)
- TMP/SMX (most *S. aureus* including: MRSA, GN aerobes, *Pneumocystis*)
- nitrofurantoin (GN bacilli, *S. saprophyticus*, *Enterococcus*)
- metronidazole (anaerobes including: *C. difficile*; *Trichomonas*, *Entamoeba*)
- treatment for *C. difficile*: metronidazole OR oral vancomycin; consider both in serious infection

Antimicrobials

Antibiotics

- empiric antibiotic therapy
 - choose antibiotic(s) to cover for most likely and lethal organisms for the type of infection prior to obtaining laboratory results (usually reserved for serious infections)
 - adjust antibiotic(s) based on C&S
 - ♦ if causative organism identified, use antibiotic to which organism is sensitive
 - ♦ if causative organism not identified, re-evaluate need for ongoing antimicrobial therapy (and continue with empiric antibiotic(s) if indicated)

Reasons for Combination Therapy

- Polymicrobial infection
- Empiric therapy pending culture results
- Synergy for difficult to treat pathogens (e.g. *Enterococcus* spp. causing endocarditis)
- To prevent emergence of resistance

Bactericidal Antibiotics	Bacteriostatic Antibiotics
"Very Finely Proficient At CCell Murder"	"ECSTaTiC"
Vancomycin	Erythromycin (and other macrolides)
Fluoroquinolones	Clindamycin
Penicillin	Sulfamethoxazole
Aminoglycosides	Trimethoprim
Cephalosporins	Tetracyclines
Carbapenems	Chloramphenicol
Metronidazole	
Daptomycin	

Figure 20. Mechanism of action of antibiotics

Table 31. Antibiotics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications		
CELL WALL INHIBITORS							
Penicillins							
Benzyl penicillin - penicillin G IV/IM - penicillin V PO	GP <u>except</u> <i>Staphylococcus</i> , <i>Enterococcus</i> , <i>N. meningitidis</i> , Oral anaerobes Syphilis	Bactericidal: β -lactam inhibits cell wall synthesis by binding penicillin binding protein (PBP) preventing cross-linking of peptidoglycan	Immediate allergy (IgE): anaphylaxis, urticaria Late-onset allergy (IgG): urticaria, rash, serum sickness Interstitial nephritis Dose related toxicity: seizures Diarrhea	Mild to moderately severe infections caused by susceptible organisms including actinomycosis, streptococcal pharyngitis, streptococcal skin and soft tissue infections, pneumococcal pneumonia, syphilis	Hypersensitivity to penicillin cov		
Aminopenicillin - ampicillin IV - amoxicillin PO (Amoxil®)	Same as penicillin AND <i>Enterococcus</i> <i>Listeria</i> selectively <i>H. influenzae</i> , <i>E. coli</i> , <i>K. pneumoniae</i>	See above	See above	Bacterial meningitis and endocarditis (IV ampicillin), acute otitis media (AOM), streptococcal pharyngitis, sinusitis, acute exacerbations of COPD, part of multidrug therapy for <i>H. pylori</i> treatment, Lyme disease, pneumococcal pneumonia; UTI (amoxicillin and ampicillin) for most enterococci and susceptible gram-negative pathogens	Hypersensitivity to penicillin or β -lactam antibiotics		
Isoxazoyl penicillin - cloxacillin - methicillin - nafcillin - oxacillin	Methicillin-sensitive <i>Staphylococcus aureus</i> ; streptococci	See above	See above	Bacterial infections caused by staphylococci and streptococci including skin and soft-tissue infections	Hypersensitivity to cloxacillin or any penicillin		
β -lactam/ β -lactamase inhibitor combinations - amoxicillin-clavulanate (Clavulin®, Augmentin®) - piperacillin/tazobactam (Tazocin®)	Same as penicillin AND <i>Staphylococcus</i> <i>H. influenzae</i> <i>Enterococcus</i> Anaerobes (oral and gut)	β -lactamases produced by certain bacteria inactivate β -lactams Lactamase inhibitors prevent this process, preserving antibacterial effect of β -lactams	See above	Various β -lactamase producing bacteria, Clavulin® sensitive bacteria including RTI, sinusitis, AOM, skin and soft tissue infections, UTI, and severe intra-abdominal and pelvic infections	Hypersensitivity to penicillin or cephalosporin History of Clavulin®-associated jaundice or hepatic dysfunction		
Cephalosporins							
PO 1° cephalexin (Keflex®)	IV cefazolin (Ancef®)	GP Good with the exception of <i>Enterococcus</i> and MRSA	GN <i>E. coli</i> , <i>Klebsiella</i> , <i>Proteus</i> , <i>H. influenzae</i> (not all isolates)	Bactericidal: β -lactam inhibits PBP, prevents cross-linking of peptidoglycan, less susceptible to penicillinases	10% penicillin allergy cross-reactivity Nephrotoxicity	Skin and soft tissue infections, prevention of surgical site infections (cefazolin); infections caused by susceptible organisms (especially <i>Staph</i> and <i>Strep</i> infections)	Hypersensitivity to cephalosporins or other β -lactam antibiotics
2° cefuroxime (Ceftin®) cefprozil (Cefzil®)	cefuroxime (Zinacef®) cefoxitin ^A	Weaker activity than 1°	More coverage than 1° (^A includes anaerobes)	See above	See above	Upper and lower respiratory tract infections; pneumococcal pneumonia; soft tissue infections	See above
3° cefixime (Suprax®)	ceftriaxone (Rocephin®) cefotaxime (Claforan®) ceftazidime ^B (Fortaz®)	<i>S. aureus</i> + streptococcal coverage (cefotaxime and ceftriaxone) especially <i>S. pneumoniae</i>	Broad coverage (^B includes <i>Pseudomonas</i> for ceftazidime only)	See above	~1% penicillin allergy cross-reactivity	Community-acquired pneumonia (cefotaxime, ceftriaxone), gonorrhea (use ceftriaxone), community-acquired bacterial meningitis (ceftriaxone, cefotaxime); abdominal and pelvic infections (cefotaxime or ceftriaxone in combination with metronidazole); once-daily administration makes ceftriaxone convenient for outpatient IV therapy	Severe hypersensitivity (Type I) to other β -lactam antibiotics
4°	cefepime (Maxipime®)	Broad spectrum	Broad coverage including <i>Pseudomonas</i>	See above	See above	Empiric therapy for febrile neutropenia	See above

Table 31. Antibiotics (continued)

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
CELL WALL INHIBITORS					
Carbapenems					
imipenem (Primaxin®)	GP except MRSA GN including <i>Pseudomonas</i> + <i>Enterobacter</i> , ESBLs, anaerobes	β -lactam inhibits PBP and prevents cross-linking of peptidoglycan	Penicillin allergy cross-reactivity Seizures	Treatment of infections caused by GNB producing extended-spectrum β -lactamases, serious infections caused by susceptible organisms	Hypersensitivity to imipenem
meropenem (Merrem®)	See above; does not cover <i>Enterococcus</i>	See above	See above	See above	Hypersensitivity to β -lactams
ertapenem (Invanz®)	GP <u>except</u> <i>Enterococcus</i> , MRSA GN including <i>Enterobacter</i> (but not <i>Pseudomonas</i>), anaerobes	See above	See above	See above; once-daily administration makes it convenient for outpatient IV therapy	Hypersensitivity to β -lactams
Glycopeptides					
Vancomycin (Vancocin®)	GP including MRSA, not VRE <i>C. difficile</i> if PO	Glycopeptide sterically inhibits cell wall synthesis	Red Man Syndrome Nephrotoxicity Ototoxicity Thrombocytopenia	Severe or life-threatening GP infections, patients with β -lactam allergy May only be taken orally for severe <i>C. difficile</i> infection	Hypersensitivity to vancomycin
PROTEIN SYNTHESIS INHIBITORS (50S RIBOSOME)					
Macrolides					
erythromycin (Erybid®, Eryc®)	GP <u>except</u> <i>Enterococcus</i> GN: <i>Legionella</i> , <i>B. pertussis</i> "Atypicals": <i>Chlamydomphila</i> , <i>Mycoplasma</i> *This agent is rarely used due to GI upset	Binds to 50S ribosomal subunit inhibiting protein synthesis	GI upset Acute cholestatic hepatitis Prolonged QT	Susceptible RTI, pertussis, diphtheria, Legionnaires' disease, skin and soft tissue infections	Hypersensitivity to erythromycin Concurrent therapy with astemizole, terfenadine
clarithromycin (Biaxin®)	See above, some mycobacteria	See above	See above	Susceptible RTI, skin infections, non-tuberculous mycobacterial infections, part of multidrug therapy for <i>H. pylori</i> treatment	Hypersensitivity to macrolides
azithromycin (Zithromax®)	See above, some mycobacteria	See above	See above	Susceptible RTI, acute exacerbations of COPD, community-acquired pneumonia, skin infections, <i>Campylobacter</i> infections if treatment indicated, chlamydia	Hypersensitivity to macrolides
Lincosamides					
clindamycin (Dalacin®)	GP <u>except</u> <i>Enterococcus</i> , most community-acquired MRSA Anaerobes	Inhibits peptide bond formation at 50S ribosome	Pseudomembranous colitis GI upset	Treatment of suspected or proven infections caused by GP anaerobes including skin and skin structure infections, oropharyngeal infections, in combination with GN coverage for intra-abdominal and pelvic infections	Hypersensitivity to clindamycin Infants < 30 d
chloramphenicol	GP GN Anaerobes	Inhibits peptidyl transferase action of tRNA at 50S ribosome	Aplastic anemia Grey Baby Syndrome	Serious infections by susceptible organisms when suitable alternatives are not available including meningococcal disease in patients with anaphylaxis to β -lactams	Hypersensitivity to chloramphenicol
linezolid (Zyvoxam®)	GP including VRE + MRSA	Binds 50S ribosome and prevents functional 70S initiation complex	HTN (acts as MAOI) Risks with prolonged use: myelosuppression optic neuropathy, peripheral neuropathy	Vancomycin-resistant <i>Enterococcus faecium</i> infections including intra-abdominal, skin and skin structure, and urinary tract infections, MRSA infections as outpatient therapy	Hypersensitivity to linezolid

Table 31. Antibiotics (continued)

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
PROTEIN SYNTHESIS INHIBITORS (30S RIBOSOME)					
Aminoglycosides					
gentamicin tobramycin amikacin (Amikin®)	GN (includes <i>Pseudomonas</i>)	Binds 30S subunit of ribosome inhibiting protein synthesis	Nephrotoxicity (reversible) Vestibular and ototoxicity (irreversible) Vestibular toxicity is the most important aminoglycoside toxicity	GN infections when alternatives do not exist, UTIs, used in low doses for synergy with β -lactams or with vancomycin for the treatment of serious enterococcal infections	Pre-existing hearing loss and renal dysfunction
Tetracyclines					
tetracycline (Apo-Tetra®, Nu-Tetra®) minocycline (Minocin®) doxycycline (Doxycin®) tigecycline (Tygacil®)	GP Anaerobes "Atypicals": <i>Chlamydomphila</i> , <i>Mycoplasma</i> , <i>Rickettsia</i> , <i>Borrelia burgdorferi</i> <i>Treponema</i> Malaria prophylaxis (doxycycline) Tigecycline has activity against MRSA, VRE, and ESBL-producing <i>E. coli</i> / <i>K. pneumoniae</i>	Binds 30S subunit of ribosome inhibiting protein synthesis	GI upset Hepatotoxicity Fanconi's syndrome Photosensitivity Teratogenic Yellow teeth and stunted bone growth in children	Rickettsial infections, <i>Chlamydomphila</i> , acne (tetracycline, minocycline), PID (step-down), malaria prophylaxis (doxycycline)	Severe renal or hepatic dysfunction Pregnancy or lactation Children under 8 yr
TOPOISOMERASE INHIBITORS					
Fluoroquinolones (FQs)					
ciprofloxacin (Cipro®) norfloxacin (Apo-Norfloxx®) ofloxacin (Floxxin®) Respiratory FQs: levofloxacin (Levaquin®) moxifloxacin (Avelox®)	Poor GP activity GN (includes <i>Pseudomonas</i>) Atypicals Levofloxacin and Moxifloxacin cover <i>S. pneumoniae</i> Moxifloxacin also covers many anaerobes	Inhibits DNA gyrase	H/A, dizziness Allergy Seizures Prolonged QT Dysglycemia (levofloxacin, moxifloxacin) Tendonitis Tendon rupture	Upper and lower RTI (not ciprofloxacin unless susceptible organism isolated), UTI, prostatitis (not moxifloxacin), bone and joint infections for susceptible organisms, skin and soft tissue infections (levofloxacin, moxifloxacin), infectious diarrhea, meningococcal prophylaxis, intra-abdominal infections (moxifloxacin, ciprofloxacin in combination with metronidazole or clindamycin), febrile neutropenia prophylaxis (ciprofloxacin, levofloxacin) or ciprofloxacin in combination with amoxicillin-clavulanate low management of "low-risk" febrile neutropenia	
OTHER					
Rifampin	GP cocci <i>N. meningitidis</i> <i>H. influenzae</i> <i>Mycobacteria</i>	Inhibits RNA polymerase	Hepatic dysfunction, P450 enzyme induction Orange tears/saliva/urine	Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment of other mycobacterial infections, endocarditis involving prosthetic valve or other prosthetic device infections in combination with other antibiotic agents, prophylaxis for those exposed to people with <i>N. meningitidis</i> or HiB meningitis	Jaundice Not to be used as monotherapy (except for prophylaxis)
Metronidazole (Flagyl®)	Anaerobes Protozoa	Forms toxic metabolites in bacterial cell which damage microbial DNA	Disulfiram-type reaction with EtOH Seizures Peripheral neuropathy	Protozoal infections (trichomoniasis, amoebiasis, giardiasis), bacterial vaginosis, anaerobic bacterial infections	
Daptomycin	GP, including MRSA and VRE	Hypothesized to bind to cell wall and form channels leading to intracellular K ⁺ depletion	Skeletal muscle injury at high doses (elevated CPK) Peripheral neuropathy	Bacteremia, endocarditis, skin and soft tissue, and other infections due to resistant GP infections including MRSA and VRE	Known hypersensitivity

Table 31. Antibiotics (continued)

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Indications	Contraindications
ANTI-METABOLITE					
Trimethoprim-Sulfamethoxazole (TMP/SMX) (Septra®, Bactrim®)	GP, especially <i>S. aureus</i> (including most MRSA) GN: enteric <i>Nocardia</i> Other: <i>Pneumocystis</i> , <i>Toxoplasmosis</i>	Inhibits folic acid pathway (TMP inhibits DHFR and SMX competes with PABA)	Hepatitis Stevens-Johnson syndrome Bone marrow suppression Hyperkalemia Drug toxicity (increases free levels of many drugs, including glyburide, warfarin)	Susceptible UTI, RTI, GI infections, skin and soft tissue infections caused by staphylococcal species, treatment and prophylaxis of <i>P. jiroveci</i> pneumonia	Hypersensitivity to TMP-SMX, sulfa drugs
nitrofurantoin (MacroBID®, Macrochantin®)	<i>Enterococcus</i> , <i>S. saprophyticus</i> GN (coliforms)	Reactive metabolites inhibit ribosomal protein synthesis	Cholestasis, hepatitis Hemolysis if G6PD deficiency Interstitial lung disease with chronic use	Lower UTI; not pyelonephritis or bacteremia	Hypersensitivity to nitrofurantoin Anuria, oliguria, or significant renal impairment Pregnant patients during labour and delivery or when labour imminent Infants < 1 mo of age
ANTI-MYCObACTERIALS					
isoniazid (INH)	<i>Mycobacteria</i>	Inhibits mycolic acid synthesis	Hepatotoxicity Hepatitis Drug-induced SLE Peripheral neuropathy	Part of multidrug treatment for active TB, alone for treatment of latent TB	Drug-induced hepatitis or acute liver disease
rifampin (RIF)	<i>Mycobacteria</i>	Inhibits RNA polymerase	Hepatotoxicity P450 enzyme inducer Orange tears, saliva, urine	Part of multidrug treatment for active TB, alone for treatment of latent TB, part of multidrug treatment of other mycobacterial infections	Jaundice Not to be used monotherapy (except for prophylaxis)
ethambutol	<i>Mycobacteria</i>	Inhibits mycolic acid synthesis	Loss of central and colour vision	Part of multidrug treatment for active TB and other mycobacterial infections	Renal failure
pyrazinamide (PZA)	<i>Mycobacteria</i>	Unknown	Hepatotoxicity Gout Gastric irritation	Part of multidrug treatment for active TB	Severe hepatic damage or acute liver disease Patients with acute gout
SULFONES					
dapsone sulfoxone	<i>M. leprae</i> , <i>P. jiroveci</i> , <i>Toxoplasma</i>	Inhibit folic acid synthesis by competition with PABA	Rash Drug fever Agranulocytosis	Part of multidrug treatment for <i>M. leprae</i> , part of treatment for <i>P. jiroveci</i> pneumonia (with TMP), <i>P. jiroveci</i> pneumonia prophylaxis, toxoplasmosis prophylaxis with pyrimethamine	

Table 32. Antibiotics for Selected Bacteria

<i>Pseudomonas</i>	<i>S. aureus</i>	<i>Enterococcus</i>	<i>H. influenzae</i>	Anaerobes
ciprofloxacin	cloxacillin (MSSA)	ampicillin	amoxicillin-clavulanate	metronidazole
gentamicin, tobramycin	1° cephalosporin (MSSA)	amoxicillin	2°/3° cephalosporin	clindamycin
piperacillin/tazobactam	clindamycin	vancomycin	macrolides (clarithromycin, azithromycin)	amoxicillin-clavulanate
ceftazidime	Cotrimoxazole (including MRSA)	nitrofurantoin (lower UTI)	levofloxacin	cefoxitin
cefipime	vancomycin (including MRSA)	linezolid for VRE	moxifloxacin	piperacillin/tazobactam
meropenem	linezolid (including MRSA)	daptomycin for VRE		moxifloxacin
imipenem	daptomycin (including MRSA)	tigecycline for VRE		ertapenem, imipenem, meropenem
	tigecycline (including MRSA)			

**Rifampin**

- Good adjunct for treating prosthetic device infection (bacterial biofilm)
- Always used in combination with other antibiotics to reduce emergence of resistance

Antivirals

Table 33. Antivirals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
ANTI-HERPESVIRUS				
acyclovir valacyclovir (Valtrex®) (prodrug of acyclovir)	HSV-1,2 VZV	Guanosine analog inhibits viral DNA polymerase	PO well-tolerated IV: nephrotoxicity, CNS	Hypersensitivity to acyclovir or valacyclovir
famciclovir (Famvir®) penciclovir	HSV-1,2 VZV	See above	H/A, nausea	Hypersensitivity to famciclovir or penciclovir
ganciclovir (Cytovene®) valganciclovir (prodrug of ganciclovir)	CMV HSV-1,2, VZV, HHV-6, EBV	See above	Heme: neutropenia, thrombocytopenia, anemia	Hypersensitivity to ganciclovir or valganciclovir Possible cross-hypersensitivity between acyclovir and valacyclovir
foscarnet	CMV Acyclovir-resistant HSV, VZV	Pyrophosphate analog inhibits viral DNA polymerase	Nephrotoxicity Anemia Electrolyte disturbance	Hypersensitivity to foscarnet
OTHER ANTIVIRALS				
(pegylated) interferon- α -2a or-2b	Chronic hepatitis B or C HPV	Inhibits viral protein synthesis	"Flu-like" syndrome Depression Bone marrow suppression	Hypersensitivity to any interferon Cannot use in combination with ribavirin if renal impairment
ribavirin (Virazole®)	Chronic hepatitis C RSV Lassa fever	Guanosine analog with multiple postulated mechanisms of action	Hemolytic anemia Rash, conjunctivitis Highly teratogenic	Pregnancy, women who may become pregnant or their partners Renal impairment
Cidofovir	Adenovirus CMV retinitis Acyclovir and foscarnet resistant HSV	Deoxycytidine analogue Inhibits DNA synthesis	Nephrotoxicity (proximal tubule dysfunction)	Renal failure; probenecid can reduce renal toxicity
lamivudine (EpiVir®)	Chronic hepatitis B HIV	See HIV and AIDS, ID27	See HIV and AIDS, ID27	See HIV and AIDS, ID27
Tenofovir	Chronic hepatitis B HIV	See HIV and AIDS, ID27	See HIV and AIDS, ID27	See HIV and AIDS, ID27
Neuraminidase inhibitors: zanamivir (Relenza®) oseltamivir (Tamiflu®)	Influenza A and B: treatment and prophylaxis	Inhibits neuraminidase, an enzyme required for release of virus from infected cells and prevention of viral aggregation	GI: N/V, diarrhea Bronchospasm in zanamavir	Hypersensitivity to the neuraminidase inhibitors

Antifungals

Table 34. Antifungals

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
POLYENES				
amphotericin B	Endemic mycoses: Histoplasmosis Blastomycosis Coccidioidomycosis Pulmonary: Aspergillosis CNS: <i>Cryptococcus</i>	A polyene antimicrobial: inserts into fungal cytoplasmic membrane causing altered membrane permeability and cell death	Nephrotoxicity Hypo/hyperkalemia Infusion reactions: chills, fevers, H/A Peripheral phlebitis	Renal impairment
nystatin (oral, topical)	Candidiasis: mucocutaneous, GI, oral (thrush), vaginal	See above Not absorbed from the GI tract	GI: N/V, diarrhea Highly toxic if given IV	
IMIDAZOLES				
clotrimazole (Canesten®)	Oral and vulvovaginal candidiasis Dermatomycoses	All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability	Pruritis, skin irritation	
miconazole (Monistat®, Micozole®)	Vulvovaginal candidiasis Dermatomycoses		Vaginal burning N/V	
ketoconazole (Nizoral®)	Dermatomycoses Seborrheic dermatitis		Pruritis, skin irritation GI nonspecific Results in decreased androgen and testosterone synthesis	Cross-sensitivity with other azoles possible Hepatic dysfunction Pregnant women or those that may become pregnant

Table 34. Antifungals (continued)

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
TRIAZOLES				
fluconazole (Diflucan®)	Candida infections (mucosal and invasive) Cryptococcal meningitis (step-down therapy)	All azoles: inhibit ergosterol synthesis and thereby alter fungal cell membrane permeability	Elevated liver enzymes GI nonspecific	Cross-sensitivity with other azoles unknown
itraconazole (Sporanox®)	Sporotrichosis Onychomycoses Endemic mycoses: Histoplasmosis Blastomycosis Coccidioidomycosis		Elevated liver enzymes Rash GI nonspecific HTN Hyperkalemia Peripheral edema	Cross-sensitivity with other azoles unknown Severe ventricular dysfunction
voriconazole (Vfend®)	Aspergillus Candidiasis		Visual disturbance (30%) Hepatotoxicity Cutaneous photosensitivity Cutaneous squamous cell carcinoma with long-term use in immunosuppressed patients Prolonged QT Periostitis Neurologic toxicity	Cross-sensitivity with other azoles unknown May avoid or alter doses if co-administered with other CYP3A4 substrates, rifampin, carbamazepine, long-acting barbiturates, ritonavir, efavirenz, sirolimus, rifabutin, ergot alkaloids
posaconazole (Posanol®, Noxafil®)	Candidiasis Aspergillus Mucormycosis		Elevated liver enzymes H/A Prolonged QT	Coadministration of cisapride, ergot alkaloids, pimozide, quinidine, or sirolimus
ALLYLAMINES				
terbinafine (Lamisil®)	Dermatomycoses Onychomycoses	Inhibits enzyme needed for ergosterol synthesis	Rash, local irritation GI nonspecific, transaminitis	Active liver disease
ECHINOCANDINS				
casprofungin micafungin anidulafungin	Refractory aspergillus, candidemia (azole-resistant)	Inhibits 1-3 β-D-glucan synthesis (needed for fungal cell wall)	Hepatotoxicity Infusion and injection site reactions	

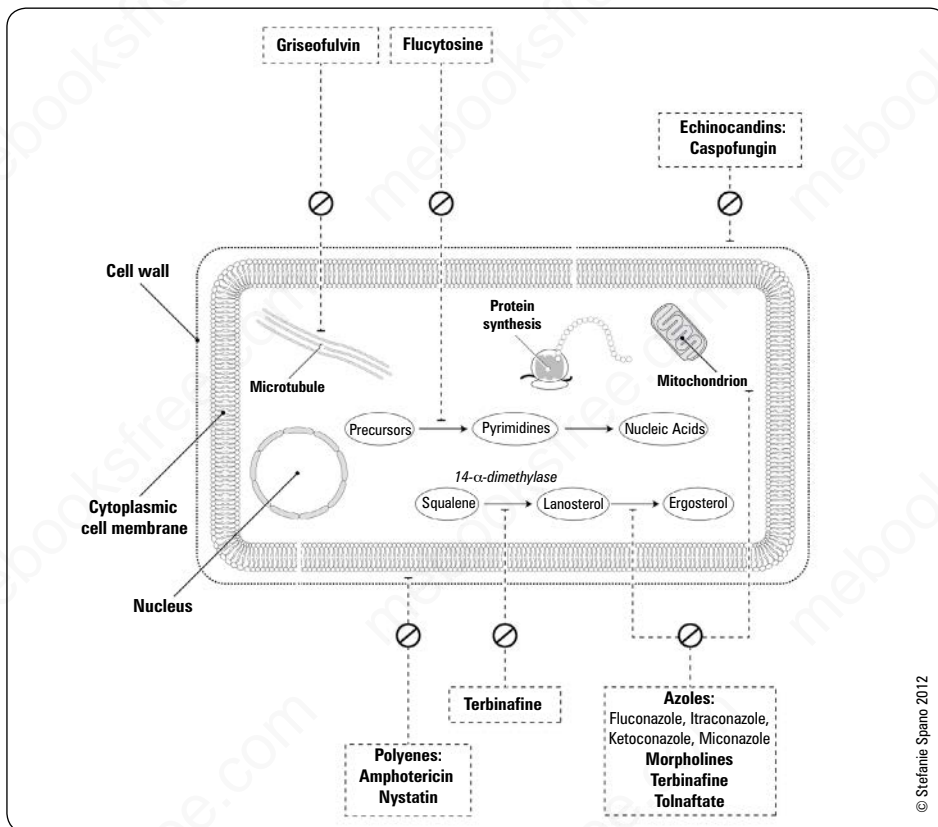

Figure 21. Mechanism of action of antifungals

© Stefanie Spano 2012

Antiparasitics

Table 35. Antiparasitics

Class and Drugs	Coverage	Mechanism of Action	Adverse Effects	Contraindications
ANTIMALARIALS				
chloroquine	Malaria: treatment of erythrocytic phase of all five species of <i>Plasmodium</i> that infect humans Note: High resistance of <i>P. falciparum</i> and <i>P. vivax</i> in certain geographic areas	Inhibits parasite heme polymerase	CNS: blurred vision, retinopathy, dizziness Nonspecific GI (rare with prophylaxis)	Hypersensitivity to chloroquine or other 4-aminoquinoline Retinal or visual field changes due to 4-aminoquinoline
quinine	Malaria: treatment of all five species of <i>Plasmodium</i> that infect humans, including chloroquine-resistant <i>P. falciparum</i>		Cinchonism: ears (tinnitus, vertigo), eyes (visual disturbance), GI (N/V, diarrhea), CNS (H/A, fever) Hypoglycemia	Hypersensitivity to quinine, may have cross-sensitivity with quinidine Patients with G6PD deficiency, tinnitus, optic neuritis, hypoglycemia, history of blackwater fever or thrombocytopenic purpura due to quinine use
mefloquine (Lariam®)	Malaria: prophylaxis		CNS/Psych: irritability, nightmares, psychoses, suicide, depression, seizures, H/A	History of seizures, psychosis, severe anxiety or depression
primaquine	Malaria: treatment of liver hypozoites of <i>P. vivax</i> and <i>P. ovale</i> ; prophylaxis of all <i>Plasmodium</i> spp. <i>Pneumocystis jiroveci</i> (with clindamycin)	Interferes with mitochondrial function	Hemolytic anemia in G6PD deficient GI upset (take with food)	GI nonspecific G6PD deficiency Concurrent or recent use of quinacrine Pregnancy
atovaquone/proguanil (Malarone®)	Malaria: treatment and prophylaxis of <i>P. falciparum</i>	Inhibits mitochondrial electron transport and dihydrofolate reductase	N/V, anorexia, diarrhea, abdominal pain (take with food)	Hypersensitivity to atovaquone or proguanil Severe renal impairment
artemisinin derivatives (artemether, artesunate, etc.) Note: marketed primarily in endemic countries	Malaria: treatment of all <i>Plasmodium</i> spp. Severe malaria (IV artesunate) Typically used in combination with a longer-acting agent from above	Binds iron, leading to formation of free radicals that damage parasite proteins	Transient neurologic deficits (nystagmus, balance disturbance) Transient neutropenia (at high doses of oral artesunate) Transient neutropenia (at high doses of oral artesunate) Delayed hemolysis	Hypersensitivity to artemisinins
OTHER ANTI-PROTOZOAL				
iodoquinol (Diodoquin®)	Amoebiasis: <i>E. histolytica</i> , <i>Dientamoeba fragilis</i> , <i>Balantidium coli</i> , <i>Blastocystis hominis</i>	Contact amoebicide that acts in intestinal lumen by uncertain mechanism	GI: N/V, diarrhea, abdominal pain CNS: H/A, seizures, encephalitis	Hypersensitivity to any 8-hydroxy-quinoline or iodine Patients with hepatic damage or optic neuropathy Pregnancy
metronidazole	Amoebiasis, <i>T. vaginalis</i> , giardiasis, <i>D. fragilis</i>	See <i>Antibiotics</i> , ID49		
nitazoxanide	<i>Cryptosporidium</i> , giardiasis, cyclosporiasis	Interferes with parasite anaerobic metabolism	N/V, diarrhea, abdominal pain, H/A	Hypersensitivity to nitazoxanide
ANTI-HELMINTHICS				
praziquantel	<i>Schistosomiasis</i> and other flukes Tapeworms	Increases Ca ²⁺ permeability of helminth cell membrane, causing paralysis and detachment	N/V, fever, dizziness	Ocular cysticercosis
albendazole	Intestinal roundworms <i>Neurocysticercosis</i> <i>Echinococcus</i> Hydatid disease	Inhibits glucose uptake into susceptible parasites	Elevated liver enzymes Alopecia GI nonspecific Agranulocytosis	Pregnancy Ocular cysticercosis or intraventricular cysticercosis
mebendazole (Vermox®)	Intestinal roundworms: pinworm, whipworm, hookworm, roundworm (e.g. <i>Ascaris</i>)	Inhibits microtubule formation and glucose uptake	Nonspecific GI	Pregnancy, infants
ivermectin	<i>Strongyloidiasis</i> <i>Onchocerciasis</i> Scabies	Interferes with polarization of nerve and muscles cells in susceptible parasites leading to paralysis	Nausea, bloating, diarrhea, myalgias, lightheadedness, H/A	Hypersensitivity to ivermectin Pregnancy
diethylcarbamazine	<i>Wuchereria bancrofti</i> <i>Loa loa</i>		Anorexia, N/V, H/A, drowsiness, encephalitis, retinal hemorrhage Mazzotti reaction if coinfectd with onchocerciasis	Pregnancy Onchocerciasis

FTS	first trimester screening	US	ultrasound
IPS	integrated prenatal screening		

Introduction to Genetics

Background

Terms

- **Penetrance:** extent that a gene is observably expressed in an individual that carries it
- **Expressivity:** extent of gene expression
- **Genetic heterogeneity:** genetic disorder can arise from different allele/locus mutations
- **Phenotypic heterogeneity:** mutations in the same gene resulting in multiple diverse clinical manifestations and degree of severity
- **Imprinting:** epigenetic process that involves methylation or acetylation of DNA, affecting gene expression
- **Uniparental disomy:** two full or partial copies of a chromosome from one parent and no chromosome from the other parent

Mendelian Inheritance

- disorders caused by mutation of one or both copies (alleles) of a gene, inherited in one of two patterns
 - autosomal: when disorder is caused by genes on one of 22 pairs of autosomes (chromosomes 1-22)
 - X-linked: when disease is caused by a gene on the X chromosome

Triplet Repeat Expansions

- disorder in which trinucleotide repeats in certain genes exceed the normal number and result in altered gene expression or production of an abnormal protein (e.g. Fragile X syndrome, Huntington's disease)

Imprinting Disorders

- imprinted genes are expressed entirely from either the maternal or paternal allele, depending on the gene (parent-of-origin gene expression)
- occur when a mutation disrupts the normally expressed allele of imprinted gene (e.g. Prader-Willi syndrome, Angelman syndrome, Beckwith-Wiedemann syndrome) or through uniparental disomy of the normally silenced allele

Mitochondrial Disorders

- disorders caused by mutations of the DNA present in mitochondria or nuclear genes whose protein products are important for mitochondrial function
- inheritance pattern of mitochondrial DNA mutations: mother passes on the defect to all her children; father cannot pass on defect since embryo only receives mitochondria from the mother (in the egg)

Copy Number Variation

- difference in the amount of genetic material
 - decrease: deletion of a chromosomal region, leaving only one copy of the genetic material in that region (e.g. 22q11.2 deletion syndrome due to deletion on chromosome 22)
 - increase: duplication of a chromosomal region, resulting in more than two copies of the genetic material in that region (e.g. Potocki-Lupski syndrome due to duplication of chromosome 17p11.2)
- CNVs can be part of normal range of genetic variation

Pedigrees

- diagrams that show the pattern/distribution of phenotypes for a genetic disorder within a family, often across multiple generations

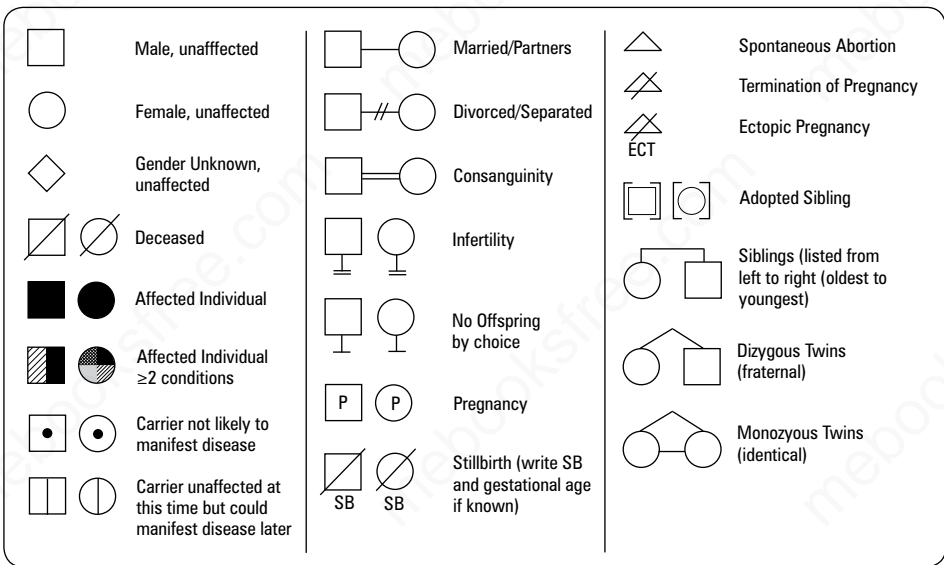

Figure 1. Common pedigree symbols

Genetic Testing and Counselling

- microarray analysis
 - array comparative genomic hybridization (CGH): a collection of DNA probes attached to a solid surface to which test DNA hybridizes in order to determine copy number of DNA regions
 - microarray analysis can identify small deletions or duplications of genetic material anywhere in the genome
 - commonly indicated when there is developmental delay OR two or more congenital anomalies
- FISH (fluorescence *in situ* hybridization): a DNA probe used to identify a gain or loss of chromosomal material
- karyotype: microscopic analysis of chromosomes with a special stain that shows large changes in the number or structure of chromosomes; can detect large CNVs
- Sanger sequencing: the 'gold-standard' method for identification of single nucleotide variants in short DNA sequences (e.g. the exons of the gene(s) known to cause suspected syndrome)
- next-generation sequencing: high-throughput method to sequence exomes or whole-genomes; useful when genetic syndrome is suspected, but diagnosis is unclear: increasingly used for multi-gene test panels
- prenatal screening
 - offer optional prenatal screening before diagnostic testing
 - first trimester screening (FTS)
 - biochemistry (β-hCG, PAPP-A)
 - US estimate of gestational age and measurement of nuchal translucency
 - screen for trisomy 21 and 18
 - done between 11 and 14 wk, sensitivity=80-85%
 - integrated prenatal screening (IPS)
 - ONTD, trisomy 21 and 18
 - use results from FTS and combine with additional biomarkers completed between 15-21 weeks (inhibin A, unconjugated estradiol, AFP, 2nd trimester β-hCG)
 - improved sensitivity, reduced false positive rate compared to FTS
 - fetal anatomy scan
 - US at 18-20 wk
- newborn screening
 - detect potentially fatal, treatable disorders before symptoms begin to allow for early therapy
 - performed on all newborns in Canada
 - heel puncture to collect blood
 - screens for CF, congenital hypothyroidism, congenital adrenal hyperplasia, SCID, hemoglobinopathies, metabolic diseases, etc.

Whole-Genome Sequencing Expands Diagnostic Utility and Improves Clinical Management in Paediatric Medicine

Genomic Med 2016;1:15012

While the standard of care for neurodevelopmental and congenital malformations is chromosome microarray analysis for copy-number variations, whole exome sequencing allows the identification of sequence-level mutations across all known coding genes. Whole genome sequencing has been previously associated with a diagnostic yield of ~25% for neurological disorders or congenital anomalies. A recent study published in *Genomic Medicine* has demonstrated that whole genome sequencing exceeds other technologies in detecting genetic variants with a 34% diagnostic yield, a four-fold increase in molecular diagnosis relative to chromosome microarray analysis and a two-fold increase relative to all genetic testing protocols. These results suggest that whole genome sequencing may be used as a first-tier molecular test in individuals with developmental delays and congenital abnormalities, with a higher diagnostic yield than conventional genetic testing and decreased time to genetic diagnosis.

Dysmorphisms

Congenital Anomalies

Minor and Major Anomalies

- minor anomaly: an unusual anatomic feature that is of no serious medical or cosmetic consequence to the patient
- major anomaly: anomaly that creates significant medical, surgical, or cosmetic problems for the patient

Mechanism for Anomalies

- malformation: results from an intrinsically abnormal developmental process (e.g. polydactyly)
- disruption: results from the extrinsic breakdown of, or interference with, an originally normal developmental process (e.g. amniotic band disruption sequence)
- deformation: alteration of the final form of a structure by mechanical forces (e.g. Potter deformation sequence)
- dysplasia: abnormal development that results in abnormal organization of cells into tissues (e.g. bone dysplasia)

Multiple Anomalies

- association: non-random occurrence of multiple independent anomalies that appear together more than would be predicted by chance but are not known to have a single etiology (e.g. VACTERL)
- sequence: related anomalies that come from a single initial major anomaly or precipitating factor that changes the development of other surrounding or related tissues or structures (e.g. Potter sequence or Pierre-Robin sequence)
- syndrome: a pattern of anomalies that occur together and are known or thought to have a single cause (e.g. Down syndrome)

VACTERL Association

- V Vertebral dysgenesis
- A Anal atresia (imperforate anus) ± fistula
- C Cardiac anomalies
- T-E TracheoEsophageal fistula ± esophageal atresia
- R Renal anomalies
- L Limb anomalies

Approach to the Dysmorphic Child

- congenital abnormalities are the most common cause of infant death in developed countries

General Approach to the Dysmorphic Child

- Are the anomalies major or minor?
- What is the mechanism underlying the anomaly?
- Do the anomalies fit as part of an association, sequence, or syndrome?

History

- prenatal/obstetrical history (see *Obstetrics, OB4*) with particular attention to potential teratogenic exposures, developmental history (see *Pediatrics, P22*), and past medical history
- complete 3 generation family pedigree: health history, consanguinity, stillbirths, neonatal deaths, specific illnesses, intellectual disability, multiple miscarriages, ethnicity

Physical Exam

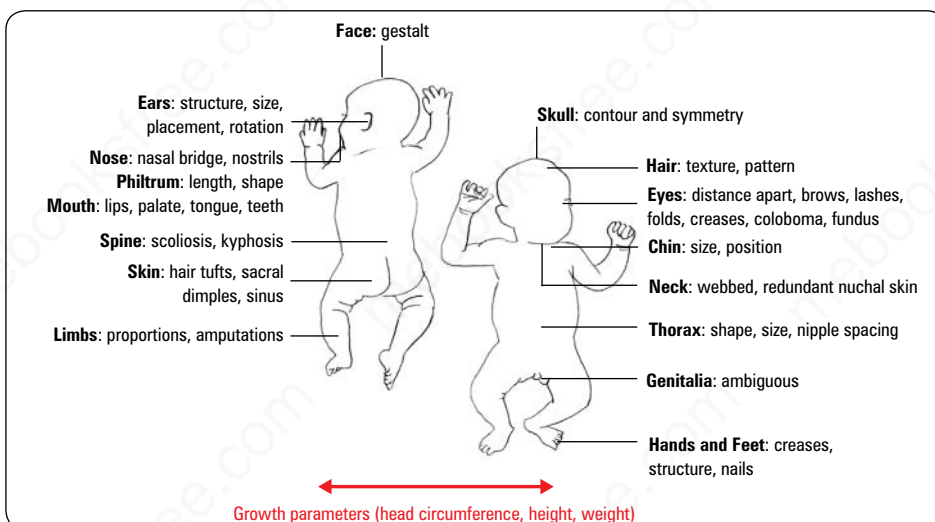

Figure 2. Physical exam of the dysmorphic child

Investigations

- screening for TORCH infections
- serial photographs if child is older
- x-rays for bony abnormalities
- cytogenetic studies
 - karyotype if recognized aneuploidy syndrome
 - chromosomal microarray analysis (array comparative genomic hybridization) if developmental delay OR two or more congenital anomalies
 - FISH if aneuploidy syndrome (e.g. trisomy 13, 18 or 21) suspected
- biochemistry: various biochemical profiles, specific enzyme assays
- single gene testing, multi-gene panel testing

Management

- prenatal counselling and assessing risk of recurrence
- referral for specialized pediatric or genetic care for symptomatic management
- specific treatments are available for certain metabolic disorders and genetic syndromes
 - metabolic disorders: enzyme replacement therapy, substrate reduction therapy, etc. (e.g. low-protein diet in PKU patients)
 - genetic syndromes: e.g. mTOR inhibitors in tuberous sclerosis

Check the umbilical cord for 2 arteries and 1 vein. The presence of a single umbilical artery may be associated with other congenital anomalies

Syndromes and Diseases

Large Genomic Changes

Table 1. Trisomy Chromosomal Syndromes

	Trisomy 21	Trisomy 18	Trisomy 13
Disease	Down syndrome	Edwards' syndrome	Patau syndrome
Incidence	1:600-800 births Most common abnormality of autosomal chromosomes Rises with advanced maternal age from 1:1,500 at age 20 to 1:20 by age 45	1:6,000 live births F:M = 3:1	1:10,000 live births
Cranium/Brain	Mild microcephaly, flat occiput, 3rd fontanelle, brachycephaly	Microcephaly, prominent occiput	Microcephaly, sloping forehead, occipital scalp defect, holoprosencephaly
Eyes	Upslanting palpebral fissures, inner epicanthal folds, speckled iris (Brushfield spots), refractive errors (myopia), acquired cataracts, nystagmus, strabismus	Microphthalmia, hypotelorism, iris coloboma, retinal anomalies	Microphthalmia, corneal abnormalities
Ears	Low-set, small, overfolded upper helix, frequent AOM, hearing loss	Low-set, malformed	Low-set, malformed
Facial Features	Protruding tongue, large cheeks, low flat nasal bridge, small nose	Cleft lip/palate Small mouth, micrognathia	60-80% cleft lip and palate
Skeletal/MSK	Short stature Excess nuchal skin Joint hyperflexibility (80%) including dysplastic hips, vertebral anomalies, atlantoaxial instability	Short stature Clenched fist with overlapping digits, hypoplastic nails, clinodactyly, polydactyly	Severe growth retardation Polydactyly, clenched hand
Cardiac Defect	50%, particularly atrioventricular septal defect	60% (VSD, PDA, ASD)	80% (VSD, PDA, ASD)
GI	Duodenal/esophageal/anal atresia, TEF, Hirschsprung's disease, chronic constipation	Hernia, TEF	
GU	Cryptorchidism, rarely fertile	Polycystic kidneys, cryptorchidism	Polycystic kidneys
CNS	Hypotonia at birth Low IQ, developmental delay, hearing problems Onset of Alzheimer's disease in 40s	Hypertonia	Hypo- or hypertonia Seizures, deafness Severe developmental delay
Other Features	Transverse palmar crease, clinodactyly, and absent middle phalanx of the 5th finger 1% lifetime risk of leukemia Polycythemia Hypothyroidism	SGA Rocker-bottom feet	Single umbilical artery Midline anomalies: scalp, pituitary, palate, heart, umbilicus, anus Rocker-bottom feet
Prognosis/Management	Prognosis: long-term management per AAP Guidelines (Health Supervision of Children with Down syndrome), recommend chromosomal analysis, CBC, Echo, yearly thyroid test, atlanto-occipital x-ray at 2 yr, sleep study, hearing test, and ophthalmology assessment	13% 1-year survival, 10% ten-year survival Profound intellectual disability in survivors	20% 1-year survival, 13% ten-year survival Profound intellectual disability in survivors

Table 2. Common Genetic Disorders Involving the Sex Chromosomes

	Fragile X Syndrome	Klinefelter Syndrome	Turner Syndrome
Genotype	X-linked Genetic anticipation CGG trinucleotide repeat on X chromosome measurable by molecular analysis	47,XXY (most common) 48,XXX,Y, 49,XXXXY	45,X (most common)
Incidence	1:3,600 males, 1:6,000 females Most common heritable cause of intellectual disability in boys	1:1,000 live male births Increased risk with advanced maternal age	1:4,000 live female births Risk not increased with advanced maternal age
Phenotype	Overgrowth: prominent jaw, forehead, and nasal bridge with long and thin face, large protuberant ears, macroorchidism, hyperextensibility, and high arched palate Complications: seizures, scoliosis, mitral valve prolapse	Tall, slim, underweight No features prepuberty Postpuberty: male may suffer from developmental delay, long limbs, gynecomastia, lack of facial hair	Short stature, short webbed neck, low posterior hair line, wide carrying angle Broad chest, widely spaced nipples Lymphedema of hands and/or feet, cystic hygroma in newborn with polyhydramnios, lung hypoplasia Coarctation of aorta, bicuspid aortic valve Renal and cardiovascular abnormalities, increased risk of HTN Less severe spectrum with mosaic
IQ and Behaviour	Mild to moderate intellectual disability, 20% of affected males have normal IQ ADHD and/or autism Female carriers may show intellectual impairment Male carriers may demonstrate tremor/ataxia syndrome in later life	Mild intellectual disability Behavioural or psychiatric disorders – anxiety, shyness, aggressive behaviour, antisocial acts	Mild intellectual disability to normal intelligence
Gonad and Reproductive Function	Premutation carrier females at risk of developing premature ovarian failure	Infertility due to hypogonadism/hypospermia	Streak ovaries with deficient follicles, infertility, primary amenorrhea, impaired development of secondary sexual characteristics
Diagnosis/Prognosis/Management	Molecular testing of <i>FMR1</i> gene: overamplification of the trinucleotide repeat, length of segment is proportional to severity of clinical phenotype (genetic anticipation)	Increased risk of germ cell tumours and breast cancer Management: testosterone in adolescence	Normal life expectancy if no complications Increased risk of X-linked diseases Management: Echo, ECG to screen for cardiac malformation GH therapy for short stature Estrogen replacement at time of puberty for development of secondary sexual characteristics

Table 3. Other Genetic Syndromes

	22q11.2 Deletion Syndrome	Prader-Willi Syndrome	Angelman Syndrome	Noonan Syndrome	CHARGE Syndrome
Genotype	Microdeletions of chromosome region 22q11.2	Lack of expression of genes on paternal chromosome 15q11-13 due to deletion, maternal uniparental disomy of chromosome 15, or imprinting defect	Lack of expression of genes on maternal chromosome 15q11-13 due to deletion or inactivation or paternal uniparental disomy	Autosomal dominant with variable expression PTPN11 mutation most common cause but multiple genes known	2/3 of children with CHARGE have been found to have a CHD7 mutation on chromosome 8
Incidence	1:4000; Second most common genetic diagnosis (next to Down syndrome)	1:15,000	1:10,000	1:2,000 male and female live births	1:10,000
Clinical Features	“CATCH 22” Cyanotic CHD Anomalies: craniofacial anomalies, micrognathia and low set ears Thymic hypoplasia: immunodeficiency Cognitive impairment Hypoparathyroidism, hypocalcemia 22q11 microdeletions High risk for schizophrenia and other psych disorders	“H₀” : Hypotonia and weakness, Hypogonadism, obsessive Hyperphagia, Obesity Short stature, almond-shaped eyes, small hands and feet with tapering of fingers Developmental delay (variable) Hypopigmentation, type 2 DM	Ataxia with severe intellectual disability, seizures, tremulousness, hypotonia Midface hypoplasia, fair hair, uncontrollable laughter	Short stature, webbed neck, triangular facies, hypertelorism, low set ears, epicanthal folds, ptosis, pectus excavatum Right-sided CHD, pulmonary stenosis Increased risk of hematological cancers, moderate intellectual disability, delayed puberty	“CHARGE” C Coloboma H congenital Heart disease R mental Retardation A choanal Atresia G GU anomalies E Ear anomalies

Table 4. Familial Cancer Syndromes

Syndrome	Gene	Associated Cancers
Li-Fraumeni Syndrome	<i>TP53</i>	Breast, osteosarcoma, leukemia, soft tissue carcinoma, and numerous other cancers
Lynch Syndrome (HNPCC)	<i>MSH2, MLH1, MSH6, PMS2, EPCAM</i>	Colorectal, endometrial, ovarian, renal, pancreatic, liver/biliary duct, stomach, brain, breast
FAP	<i>APC</i>	Colorectal, small intestine/stomach tumours
Hereditary Breast and Ovarian Cancer Syndrome	<i>BRCA1, BRCA2</i>	Female: breast, ovarian, pancreatic Male: prostate, breast, pancreatic
Von Hippel-Lindau Syndrome	<i>VHL</i>	Kidney + tumours (e.g. pheochromocytoma)
Cowden Syndrome	<i>PTEN</i>	Breast, thyroid, endometrial
NF		
Type 1	<i>NF1</i>	Astrocytoma, optic glioma, neurofibroma, leukemia
Type 2	<i>NF2</i>	Vestibular schwannoma, meningioma, ependymoma, astrocytoma

Single Gene Disorders

CYSTIC FIBROSIS

- see [Respirology, R12](#) and [Pediatrics, P82](#)

SICKLE CELL DISEASE

- see [Hematology, H20](#)

DUCHENNE MUSCULAR DYSTROPHY

Epidemiology

- 1:4,000 males

Etiology

- one type of muscular dystrophy characterized by progressive skeletal and cardiac muscle degeneration
- X-linked recessive: 1/3 spontaneous mutations, 2/3 inherited mutations
- missing structural protein (dystrophin) → muscle fibre fragility → fibre breakdown → necrosis and regeneration

Clinical Presentation

- proximal muscle weakness by age 3, positive Gower's sign, waddling gait, toe walking
- pseudohypertrophy of calf muscles (muscle replaced by fat) and wasting of thigh muscles
- decreased reflexes
- non-progressive delayed motor and cognitive development (dysfunctional dystrophin in brain)
- cardiomyopathy

Diagnosis

- molecular genetic studies of dystrophin gene (DMD) (first line)
- family history (pedigree analysis)
- increased CK (50-100x normal) and lactate dehydrogenase
- elevated transaminases
- muscle biopsy, EMG

Management

- supportive (e.g. physiotherapy, wheelchairs, braces), prevent obesity
- cardiac health monitoring and early intervention
- bone health monitoring and intervention (vitamin D, bisphosphonates)
- steroids (e.g. prednisone or deflazacort)
- surgical (for scoliosis)
- gene therapy trials underway

Complications

- patient usually wheelchair-bound by 12 yr of age
- early flexion contractures, scoliosis, osteopenia of immobility, increased risk of fracture
- death due to pneumonia/respiratory failure or CHF in 2nd-3rd decade

Gower's Sign

Child uses hands to "climb up" the legs to move from a sitting to a standing position

Metabolic Diseases

- inherited disorders of metabolism; often autosomal recessive
- infants and older children may present with FTT or developmental delay
- organelle disorders can present with dysmorphism
- universal newborn screening in Ontario includes metabolic disorders

Table 5. Metabolic Disorders

	Organic and Amino Acid Disorders	Carbohydrate Disorders	Fatty Acid Disorders	Organelle Disorders
Examples of Conditions	PKU Tyrosinemia Homocystinuria MSUD Alkaptonuria Urea cycle defects	Galactosemia GSDs: von Gierke's, Pompe's, Cori's, Andersen, McArdle	MCAD deficiency Carnitine deficiency	Mucopolysaccharidosis Congenital disorders of glycosylation Lysosomal storage diseases: Hurler's, Niemann-Pick, Tay-Sachs, Gaucher, Fabry, Krabbe
Clinical Manifestations	Irritability, lethargy, poor feeding Seizures Intellectual disability Vomiting and acidosis after feeding initiation Sweet-smelling urine (MSUD)	Vomiting and acidosis after feeding initiation Growth retardation, FTT	Lethargy, poor feeding Seizures, coma Symptoms triggered by fasting Liver dysfunction Sudden infant death	Seizures/early-onset severe epilepsy Chronic encephalopathy Developmental delay Bone crises (Gaucher) Deafness, blindness
Laboratory Findings	Hypoglycemic hyperammonemia, high anion gap (organic acidemia) Normoglycemic hyperammonemia, normal anion gap (urea cycle defects)	Hypoglycemia, hyperlipidemia (GSD)	Hypoketotic hypoglycemia Elevated free fatty acids	Elevated urine oligosaccharides (oligosaccharidoses) and glycosaminoglycans (mucopolysaccharidoses) Enzyme deficiency
Physical Exam	Hypotonia/hypertonia Microcephaly, musty odour, eczema, hypopigmentation (PKU) Dark urine, pigmented sclerae, arthralgias (alkaptonuria) Lens subluxation, marfanoid appearance (homocystinuria)	Infantile cataracts (galactosemia) Hepatomegaly Muscle weakness/cramping	Hepatomegaly Hypotonia	Dysmorphic facial features Macrocephaly (Tay-Sachs, Hurler's) Hepatosplenomegaly (Niemann-Pick type A/B/C, not Tay-Sachs) Cherry-red spot on macula (Niemann-Pick type A/B, Tay-Sachs, Gaucher's) Corneal clouding (Hurler's) Infantile cataract (Fabry) Peripheral neuropathy (Fabry, Krabbe) Spasticity

Initial Investigations

- important to send lab studies at initial presentation in order to facilitate immediate diagnosis and treatment
- check newborn screening results
- electrolytes, ABGs (calculate anion gap, rule out acidosis)
- CBC with differential and smear
- blood glucose (hypoglycemia seen with organic acidemia, fatty acid oxidation defects, and GSDs)
- lactate, ammonium (hyperammonemia with urea cycle defects), plasma Ca²⁺ and Mg²⁺
- routine urinalysis: ketonuria must be investigated
- carnitine levels with acylcarnitine profile
- others: urate, urine nitroprusside, plasma amino acid screen, urine organic acids, CSF glycine, free fatty acids (3-β-hydroxybutyrate ratio >4 in fatty acid oxidation defect)
- storage diseases: urine mucopolysaccharide and oligosaccharide screen

Treatment

- varies according to inborn error of metabolism
- dietary restrictions, supplementation, enzyme replacement therapy, gene therapy, liver transplant, stem cell transplant

PHENYLKETONURIA

Epidemiology

- 1:10,000; autosomal recessive disease

Etiology

- deficiency of phenylalanine hydroxylase prevents conversion of phenylalanine to tyrosine leading to build up of toxic metabolites
- mothers who have PKU may have infants with congenital abnormalities

Clinical Presentation

- baby is normal at birth, then develops a musty odour, eczema, hypertonica, tremors, and mental retardation
- hypopigmentation due to low tyrosine (fair hair, blue eyes)

Management

- PKU screening at birth
- dietary restriction of phenylalanine starting within the first 10 d of life
- duration of dietary restriction controversial – lifelong or until end of puberty; should be resumed during pregnancy to maintain normal phenylalanine levels
- large neutral amino acid (tyrosine) replacement, BH4 enzyme treatment, phenylalanine lyase treatment are other options

GALACTOSEMIA

Epidemiology

- 1:60,000; autosomal recessive disease

Etiology

- most commonly due to deficiency of galactose-1-phosphate uridylyltransferase leading to an inability to process lactose/galactose

Clinical Presentation

- signs of liver and renal failure, jaundice, FTT, and cataracts with ingestion of lactose/galactose

Management

- elimination of galactose from the diet (e.g. dairy, breast milk)
- most infants are fed a soy-based diet

Complications

- increased risk of sepsis, especially *E. coli*
- if the diagnosis is not made at birth, liver and brain damage may become irreversible

Metabolic disease must be ruled out in any newborn who becomes acutely ill after a period of normal behaviour and development or with a **Re**family history of early infant death even if the newborn screen is negative

Imaging Modalities

X-Ray Imaging

- x-rays, or Röntgen rays, are a form of electromagnetic energy of short wavelength
- as x-ray photons traverse matter, they can be absorbed (a process known as “attenuation”) and/or scattered
- the density of a structure determines its ability to attenuate or “weaken” the x-ray beam
 - air < fat < water < bone < metal
- structures that have high attenuation (e.g. bone) appear white on the resulting images

Plain Films

- x-rays pass through the patient and interact with a detection device to produce a 2-dimensional projection image
- structures closer to the film appear sharper and less magnified
- contraindications: pregnancy (relative)
- advantages: inexpensive, non-invasive, readily available, reproducible, fast
- disadvantages: radiation exposure, generally poor at distinguishing soft tissues

Fluoroscopy

- continuous x-rays used for guiding angiographic and interventional procedures, in contrast examinations of the GI tract, and in the OR for certain surgical procedures (e.g. orthopedic, urological)
- on the fluoroscopic image, black and white are reversed so that bone and contrast agents appear dark and radiolucent structures appear light
- advantages: allows for real-time visualization of structures
- disadvantages: increased radiation dose; however, the use of pulsed fluoroscopy has reduced fluoroscopy time by 76% and radiation dose by 64% as compared with continuous fluoroscopy

Computed Tomography

- x-ray beam opposite a detector moves in a continuous 360° arc as patient is advanced through the imaging system
 - subsequent computer assisted reconstruction of anatomical structures from the axial plane
- attenuation is quantified in Hounsfield units:
 - subsequent computer assisted reconstruction of anatomical structures from the axial plane
 - adjusting the “window width” (range of Hounsfield units displayed) and “window level” (midpoint value of the window width) can maximally visualize certain anatomical structures (e.g. CT chest can be viewed using “lung”, “soft tissue”, and “bone” settings)
- contraindications: pregnancy (relative), contraindications to contrast agents (e.g. allergy, renal failure)
- advantages: delineates surrounding soft tissues, excellent at delineating bones and identifying lung/liver masses, may be used to guide biopsies, spiral/helical multidetector CT has fast data acquisition and allows 3D reconstruction, CTA is less invasive than conventional angiography
- disadvantages: high radiation exposure, soft tissue characterization is not as good in comparison with MRI, IV contrast injection, anxiety of patient when going through scanner, higher cost, and less available than plain film

Typical Effective Doses from Diagnostic Medical Exposures (in adults)*

Diagnostic Procedure Type	Equivalent Number of Chest X-Rays	Approximate Equivalent Period of Natural Background Radiation** (~3 mSv/yr)
X-Ray		
Skull	5	12 d
Cervical spine	10	3 wk

**Calculated using average natural background exposure in Canada (Health Canada: <http://www.hc-sc.gc.ca/hl-vs/iyh-vs/environ/expos-eng.php>)

Ultrasound

- high-frequency sound waves are transmitted from a transducer and passed through tissues; reflections of the sound waves are picked up by the transducer and transformed into images
- reflection (or “echo”) occurs when the sound waves pass through tissue interfaces of different acoustic densities
- structures are described based on their echogenicity; hyperechoic structures appear bright (U/S reflected) whereas hypoechoic structures appear dark (U/S waves not reflected back but pass through)
- higher U/S frequencies result in greater resolution but greater attenuation (i.e. deeper structures more difficult to visualize)
- artifacts: acoustic shadowing refers to the echo-free area located behind an interface that strongly reflects (e.g. tissue/air) or absorbs (e.g. tissue/bone) sound waves; enhancement refers to the increase in reflection amplitude (i.e. increased brightness) from objects that lie below a weakly attenuating structure (e.g. cyst)
- Duplex scan: grey-scale image that utilizes the Doppler effect to visualize the velocity of blood flow past the transducer
- Colour Doppler: assigns a colour based on the direction of blood flow (i.e. red = toward transducer, blue = away)
- advantages: relatively low cost, non-invasive, no radiation, real time imaging, may be used for guided biopsies, many different imaging planes (axial, sagittal), determines cystic versus solid
- disadvantages: highly operator-dependent, air in bowel may prevent imaging of midline structures in the abdomen, may be limited by patient habitus, poor for bone evaluation

Attenuation
 Bone (= bright) > grey matter > white matter (“fatty” myelin) > CSF > air (= dark)

Magnetic Resonance Imaging

- non-invasive imaging technique that does not use ionizing radiation and able to produce images in virtually any plane
- patient is placed in a magnetic field; protons (H⁺) align themselves along the plane of magnetization due to intrinsic polarity. A pulsed radiofrequency beam is subsequently turned on and deflects all the protons off their aligned axes due to absorption of energy from the radiofrequency beam. When the radiofrequency beam is turned off, the protons return to their pre-excitation axis, giving off the energy they absorbed. This energy is measured with a detector and interpreted by software to generate MR images
- the MR image reflects the signal intensity picked up by the receiver. This signal intensity is dependent on:
 1. hydrogen density: tissues with low hydrogen density (e.g. cortical bone, lung) generate little to no MR signal compared to tissues with high hydrogen density (e.g. water)
 2. magnetic relaxation times (T1 and T2): reflect quantitative alterations in MR signal strength due to intrinsic properties of the tissue and its surrounding chemical and physical environment

Remember that water is “white” on T2 as “World War II”

Methods to Reduce the Risk of Contrast-Induced Nephropathy

- Optimal: 0.9% NaCl at 1 ml/kg/hr for 12 hr pre-procedure and 12 hr post-contrast administration
- For same-day procedure: 0.9% NaCl or NaHCO₃ at 3 ml/kg/hr for 1-3 hr pre-procedure and for 6 hr post-contrast administration

Table 1. Differences Between Diffusion, T1- and T2-Weighted MR Imaging

Imaging Techniques	Contrast Enhancements	Main Application	Advantages
Diffusion-Weighted Imaging	Contrast dependent on the molecular motion of water Decreased diffusion is hyperintense (bright), whereas increased diffusion is hypointense (dark)	Neuroradiology	Sensitive for detection of acute ischemic stroke and differentiating an acute stroke from other neurologic pathologies Acute infarction appears hyperintense Abscess collections also show restricted diffusion
T1-Weighted	Fluid is hypointense (dark) and fat is hyperintense (bright)	Body soft tissues	Often considered an anatomic scan since they provide a reference for functional imaging
T2-Weighted	Fluid is hyperintense (bright) and fat is hypointense (dark)	Body soft tissues	Often considered a pathologic scan since they will highlight edematous areas associated with certain pathologies

Positron Emission Tomography Scans

- non-invasive technique that involves exposure to ionizing radiation (~7 mSv)
- nuclear medicine imaging technique that produces images of functional processes in the body
- current generation models integrate PET and CT technologies into a single imaging device (PET-CT) that collects both anatomic and functional information during a single acquisition
- positron-producing radioisotopes, such as ¹⁸F, are chemically incorporated into a metabolically active molecule (e.g. glucose). These are then injected into the patient, travel to the target organ, and accumulate in tissues of interest. As the radioactive substance begins to decay, gamma rays are produced, and are then detected by the PET scanner
- contraindications: pregnancy
- advantages: shows metabolism and physiology of tissues (not only anatomic); in oncology, allows for diagnosis, staging, and restaging; has predictive and prognostic value; can evaluate cardiac viability
- disadvantages: cost, ionizing radiation

Contraindications to IV Contrast

MADD Failure
 Multiple myeloma
 Adverse reaction previously
 DM
 Dehydration
 Failure (renal, severe heart)

Contrast Enhancement

Table 2. Contrast Agents

Imaging Modality	Types	Advantages	Disadvantages	Contraindications
X-Ray/CT	1. Barium (oral or rectal)	Radio-opaque substance that helps to delineate intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects		Previous adverse reaction to contrast; barium enema is contraindicated in toxic megacolon, acute colitis, and suspected perforation
	2. Iodine (IV injection)	Delineates intraluminal anatomy; may demonstrate patency, lumen integrity, or large filling defects; under fluoroscopy, may also give information on function of an organ	Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease	Previous adverse reaction to contrast, renal failure, DM, pregnancy, multiple myeloma, severe heart failure and dehydration eGFR < 60 may require preventative measures and follow-up
MRI	Gadolinium-Chelates (IV injection)	Shortens T1 relaxation time, thereby increasing signal intensity in T1-weighted sequences; gadolinium has some effect on T2-relaxation time; highlights highly vascular structures (e.g. tumours)	Risk of nephrogenic systemic fibrosis in patients with end-stage renal disease	Previous adverse reaction to contrast or if end-stage renal disease (relative contraindication)
U/S	Microbubbles (IV injection)	Since gas is highly echogenic, the microbubbles allow for echo-enhancement of a tissue		Contraindicated in individuals with right-to-left cardiac shunts or people with known hypersensitivity reactions

Chest Imaging

Chest X-Ray

Standard Views

- PA: anterior chest against film plate to minimize magnification of the heart size
- lateral: better visualization of retrocardiac space and thoracic spine (more sensitive at picking up pleural effusions)
 - helps localize lesions when combined with PA view
- AP: for bedridden patients (generally a lower quality film than PA because of enlarged cardiac silhouette)
- lateral decubitus: to assess for pleural effusion and pneumothorax in bedridden patients; however, POCUS can also be utilized for both of these purposes
- lordotic: angled beam allowing better visualization of apices normally obscured by the clavicles and anterior ribs

Figure 1. CXR views

Approach to CXR

Basics

- ID: patient name, MRN, sex, age
- date of exam
- markers: right and/or left
- technique: view (e.g. PA, AP, lateral), supine or erect
- indications for the study
- comparison: date of previous study for comparison (if available)
- quality of film: inspiration (6th anterior and 10th posterior ribs should be visible), penetration (thoracic spine should be visible) and rotation (clavicles vs. spinous process)

Analysis

- tubes and lines: check position and be alert for pneumothorax or pneumomediastinum
- soft tissues: neck, axillae, pectoral muscles, breasts/nipples, chest wall
 - nipple markers can help identify nipples (may mimic lung nodules)
 - amount of soft tissue, presence of masses and air (subcutaneous emphysema)
- abdomen (see *Abdominal Imaging, MI10*)
 - free air under the diaphragm, air-fluid levels, distention in small and large bowels
 - herniation of abdominal contents (i.e. diaphragmatic hernia)
- bones: C-spine, thoracic spine, shoulders, ribs, sternum, clavicles
 - lytic and blastic lesions and fractures
- mediastinum: trachea, heart, great vessels
 - cardiomegaly (cardiothoracic ratio >0.5), tracheal shift, tortuous aorta, widened mediastinum
- hila: pulmonary vessels, mainstem and segmental bronchi, lymph nodes
- lungs: lung parenchyma, pleura, diaphragm
 - comment on abnormal lung opacity, pleural effusions or thickening
 - right hemidiaphragm usually higher than left due to liver
 - right vs. left hemidiaphragm can be discerned on lateral CXR due to heart resting directly on left hemidiaphragm
- please refer to Toronto Notes website for supplementary material on how to approach a CXR

Chest X-Ray Interpretation

Basics ABCDEF

- AP, PA or other view
- Body position/rotation
- Confirm name
- Date
- Exposure/quality
- Films for comparison

Analysis ABCDEF

- Airways and hilar **A**denopathy
- Bones and **B**reast shadows
- Cardiac silhouette and **C**ostophrenic angle
- Diaphragm and **D**igestive tract
- Edges of pleura
- Fields (lung fields)

Anatomy

Localizing Lesions for Parenchymal Lung Disease

- silhouette sign: when two objects of the same radiolucency contact each other, they become indistinguishable on imaging and result in the loss of normal interfaces. It can be used to identify lung pathology (consolidation, atelectasis, mass) and localize disease to specific lung segments. The silhouette sign is not only used in the chest, but can also be an aid to interpreting imaging studies throughout the body
- spine sign: on lateral films, vertebral bodies should appear progressively radiolucent as one moves down the thoracic vertebral column; if they appear more radio-opaque, it is an indication of pathology (e.g. consolidation in overlying left lower lobe)
- air bronchogram: branching pattern of air-filled bronchi on a background of fluid-filled airspaces

Table 3. Localization Using the Silhouette Sign

Interface Lost	Location of Lung Pathology
SVC/right superior mediastinum	RUL
Right heart border	RML
Right hemidiaphragm	RLL
Aortic knob/left superior mediastinum	LUL
Left heart border	Lingula
Left hemidiaphragm	LLL

Figure 2. Location of fissures, mediastinal structures, and bony landmarks on CXR

Figure 3. Location of lobes of the lung

Figure 4. CT thorax windows

Computed Tomography Chest

Approach to CT Chest

- soft tissue window
 - thyroid, chest wall, pleura
 - heart: chambers, coronary artery calcifications, pericardium
 - vessels: aorta, pulmonary artery, smaller vasculature
 - lymph nodes: mediastinal, axillary
- bone window
 - vertebrae, sternum, manubrium, ribs: fractures, lytic lesions, sclerosis
- lung window
 - trachea: patency, secretions
 - bronchial trees: anatomic variants, mucus plugs, airway collapse
 - lung parenchyma: fissures, nodules, fibrosis/interstitial changes
 - pleural space: effusions
- please refer to Toronto Notes website for supplementary material on how to approach a CT chest

Table 4. Types of CT Chest

	Advantage	Disadvantage	Contrast	Indication
Standard	Scans full lung very quickly (<1 min)	Poor at evaluating diffuse disease	±	CXR abnormality Pleural and mediastinal abnormality Lung cancer staging Follow-up metastases Empyema vs. abscess
High Resolution	Thinner slices provide high definition of lung parenchyma	Only 5-10% lung is sampled	No	Hemoptysis Diffuse lung disease (e.g. sarcoidosis, hypersensitivity pneumonitis, pneumoconiosis) Pulmonary fibrosis Normal CXR but abnormal PFTs Characterize solitary pulmonary nodule
Low Dose	1/5th the radiation	Decreased detail	No	Screening Follow-up infections, lung transplant, metastases
CTA	Iodinated contrast highlights vasculature	Contrast can cause severe allergic reaction and is nephrotoxic	Yes	PE Aortic aneurysms Aortic dissection

Figure 5. Atelectasis: RML collapse

Lung Abnormalities

Atelectasis

- pathogenesis: collapse of alveoli due to restricted breathing, blockage of bronchi, external compression, or poor surfactant
- findings
 - increased opacity of involved segment/lobe, vascular crowding, silhouette sign, air bronchograms
 - volume loss: fissure deviation, hilar/mediastinal displacement, diaphragm elevation
 - compensatory hyperinflation of remaining normal lung
- differential diagnosis
 - obstructive (most common): air distal to obstruction is reabsorbed causing alveolar collapse
 - ♦ post-surgical, endobronchial lesion, foreign body, inflammation (granulomatous infections, pneumoconiosis, sarcoidosis, radiation injury), or mucous plug (cystic fibrosis)
 - compressive
 - tumour, bulla, effusion, enlarged heart, lymphadenopathy
 - traction (cicatrization): due to scarring, which distorts alveoli and contracts the lung
 - adhesive: due to lack of surfactant
 - ♦ hyaline membrane disease, prematurity

DDx of Airspace Disease

- Pus (e.g. infections such as pneumonia, non-infectious inflammatory process)
- Fluid (e.g. pulmonary edema)
- Blood (e.g. pulmonary hemorrhage)
- Cells (e.g. bronchioalveolar carcinoma, lymphoma)
- Protein (e.g. alveolar proteinosis)

Figure 6. Air bronchograms in right lung

- passive (relaxation): a result of air or fluid in the pleural space
 - ♦ pleural effusion, pneumothorax
- management: in the absence of a known etiology, persisting atelectasis must be investigated (i.e. CT thorax) to rule out a bronchogenic carcinoma

Consolidation

- pathogenesis: fluid (water, blood), inflammatory exudates, protein, or tumour in alveoli
- findings
 - air bronchograms: lucent branching bronchi visible through opacification
 - airspace nodules: fluffy, patchy, poorly defined margins with later tendency to coalesce, may take on lobar or segmental distribution
 - silhouette sign
- differential diagnosis
 - fluid: pulmonary edema, blood (trauma, vasculitis, bleeding disorder, pulmonary infarct)
 - inflammatory exudates: bacterial infections, TB, allergic hypersensitivity alveolitis, BOOP, allergic bronchopulmonary aspergillosis, aspiration, sarcoidosis
 - protein: pulmonary alveolar proteinosis
 - tumour: bronchoalveolar carcinoma, lymphoma
- management: varies depending on the pattern of consolidation, which can suggest different etiologies; should also be done in the context of clinical picture

Interstitial Disease

- pathogenesis: pathological process involving the interlobular connective tissue (i.e. “scaffolding of the lung”)
- findings
 - linear: fine lines caused by thickened connective tissue septae
 - ♦ Kerley A: long thin lines in upper lobes
 - ♦ Kerley B: short horizontal lines extending from lateral lung margin
 - ♦ Kerley C: diffuse linear pattern throughout lung
 - ♦ seen in pulmonary edema, lymphangitic carcinomatosis, and atypical interstitial pneumonias
 - nodular: 1-5 mm well-defined nodules distributed evenly throughout lung
 - ♦ seen in malignancy, pneumoconiosis, and granulomatous disease (e.g. sarcoidosis, miliary TB)
 - reticular (honeycomb): parenchyma replaced by thin-walled cysts suggesting extensive destruction of pulmonary tissue and fibrosis
 - ♦ seen in IPF, asbestosis, and CVD
 - ♦ watch for pneumothorax as a complication
 - reticulonodular: combination of reticular and nodular patterns
 - may also see signs of airspace disease (atelectasis, consolidation)
- differential diagnosis
 - occupational/environmental exposure
 - ♦ inorganic: asbestosis, coal miner’s pneumoconiosis, silicosis, berylliosis, talc pneumoconiosis
 - ♦ organic: hypersensitivity pneumonitis, bird fancier’s lung, farmer’s lung (mouldy hay), and other organic dust
 - autoimmune: CVD (e.g. rheumatoid arthritis, scleroderma, SLE, polymyositis, mixed connective tissue disease), IBD, celiac disease, vasculitis
 - drug-related: antibiotics (cephalosporins, nitrofurantoin), NSAIDs, phenytoin, carbamazepine, fluoxetine, amiodarone, chemotherapy (e.g. methotrexate), heroin, cocaine, methadone
 - infections: non-tuberculous mycobacteria, certain fungal infections
 - idiopathic: hypersensitivity pneumonitis, IPF, BOOP
 - for Causes of *Interstitial Lung Disease Classified by Distribution*, see [Respirology, R13](#)
 - management: high-resolution CT thorax and biopsy

Pulmonary Nodule

- findings: round opacity ± silhouette sign
 - note: do not mistake nipple shadows for nodules; if in doubt, repeat CXR with nipple markers
- differential diagnosis
 - extrapulmonary density: nipple, skin lesion, electrode, pleural mass, bony lesion
 - solitary nodule
 - ♦ tumour: carcinoma, hamartoma, metastasis, bronchial adenoma
 - ♦ inflammation: histoplasmosis, tuberculoma, coccidioidomycosis
 - ♦ vascular: AV fistula, pulmonary varix (dilated pulmonary vein), infarct, embolism
 - multiple nodules: metastases, abscess, granulomatous lung disease (TB, fungal, sarcoid, rheumatoid nodules, silicosis, GPA)
- management: clinical information and CT appearance determine level of suspicion of malignancy
 - if high probability of malignancy, invasive testing (fine needle aspiration, transbronchial/trans-thoracic biopsy) is indicated
 - if low probability of malignancy, repeat CXR or CT in 1-3 mo and then every 6 mo for 2 yr; if no change, then >99% chance benign

Figure 7. Consolidation: bacterial pneumonia

Figure 8. Interstitial disease: fine reticular pattern

Figure 9. Interstitial disease: medium reticular pattern

DDx of Interstitial Lung Disease

FASSTEN (upper lung disease)

Farmer’s lung (hypersensitivity pneumonitis)
Ankylosing spondylitis
Sarcoidosis
Silicosis
TB
Eosinophilic granuloma (Langerhans cell histiocytosis)
Neurofibromatosis

BAD RASH (lower lung disease)

BOOP
Asbestos
Drugs (nitrofurantoin, hydralazine, isoniazid, amiodarone, many chemotherapy drugs)
Rheumatological disease
Aspiration
Scleroderma
Hamman Rich (IPF) and idiopathic pulmonary fibrosis

DDx for Cavitating Lung Nodule

WEIRD HOLES

GPA (Wegener’s)
Embolic (pulmonary, septic)
Infection (anaerobes, pneumocystis, TB)
Rheumatoid (necrobiotic nodules)
Developmental cysts (sequestration)
Histiocytosis
Oncological
Lymphangioliomyomatosis
Environmental, occupational
Sarcoidosis

Table 5. Characteristics of Benign and Malignant Pulmonary Nodules

	Malignant	Benign
Margin	Ill-defined/spiculated ("corona radiata")	Well-defined
Contour	Lobulated	Smooth
Calcification	Eccentric or stippled	Diffuse, central, popcorn, concentric
Doubling Time	20-460 d	<20 d or >460 d
Other Features	Cavitation, collapse, adenopathy, pleural effusion, lytic bone lesions, smoking history	
Size	>3 cm	<3 cm
Cavitation	Yes, especially with wall thickness >15 mm, eccentric cavity, and shaggy internal margins	No
Satellite Lesions	No	Yes

**Figure 10. Pulmonary nodule: bronchogenic carcinoma**

Pulmonary Vascular Abnormalities

Pulmonary Edema

- pathogenesis: fluid accumulation in the airspaces of the lungs
- findings
 - vascular redistribution/enlargement, cephalization, pleural effusion, cardiomegaly (may be present in cardiogenic edema and fluid overloaded states)
 - fluid initially collects in interstitium
 - ◆ loss of definition of pulmonary vasculature
 - ◆ peribronchial cuffing
 - ◆ Kerley B lines
 - ◆ reticulonodular pattern
 - ◆ thickening of interlobar fissures
 - as pulmonary edema progresses, fluid begins to collect in alveoli causing diffuse airspace disease often in a "bat wing" or "butterfly" pattern in perihilar regions with tendency to spare the outermost lung fields
- differential diagnosis: cardiogenic (e.g. CHF), renal failure, volume overload, non-cardiogenic (e.g. ARDS)

Pulmonary Embolism

- pathogenesis: arterial blockage in the lungs due to emboli from pelvic or leg veins, rarely from PICC lines, ports, air, fat, or amniotic fluid (difficult to diagnose on imaging except by combination of clinical history and CXR and CT findings of ARDS)
- findings
 - CXR: Westermark sign (localized pulmonary oligemia), Hampton's hump (triangular peripheral infarct), enlarged right ventricle and right atrium, atelectasis, pleural effusion, and rarely pulmonary edema
 - definitive imaging study: CT pulmonary angiography to look for filling defect in contrast-filled pulmonary arteries (emboli can be seen up to 4th order arterial branching)
 - V/Q scan: not a diagnostic study

**Figure 11. Peribronchial cuffing**

Pleural Abnormalities

Pleural Effusion

Table 6. Sensitivity of Plain Film Views for Pleural Effusion

X-Ray Projection	Minimum Volume to Visualize
Lateral decubitus	25 mL: most sensitive
Upright lateral	50 mL: meniscus seen in the posterior costophrenic sulcus
PA	200 mL
Supine	Diffuse haziness

- a horizontal fluid level is seen only in a hydropneumothorax (i.e. both fluid and air within pleural cavity)
- effusion may exert mass effect, shift trachea and mediastinum to opposite side, or cause atelectasis of adjacent lung
- U/S is superior to plain film for detection of small effusions and may also aid in thoracentesis, and POCUS is now standard of care in acute situations
- fluid level >1 cm on lateral decubitus film is indication to perform thoracentesis

**Figure 12. Pleural effusion in lateral view**

Pneumothorax

- pathogenesis: gas/air accumulation within the pleural space resulting in separation of the lung from the chest wall
- findings
 - upright chest film allows visualization of visceral pleura as curvilinear line paralleling chest wall, separating partially collapsed lung from pleural air
 - more obvious on expiratory (increased contrast between lung and air) or lateral decubitus films (air collects superiorly)
 - more difficult to detect on supine film; look for the “deep (costophrenic) sulcus” sign, “double diaphragm” sign (dome and anterior portions of diaphragm outlined by lung and pleural air, respectively), hyperlucent hemithorax, sharpening of adjacent mediastinal structures
 - mediastinal shift may occur if tension pneumothorax
- differential diagnosis: spontaneous (tall and thin males, smokers), iatrogenic (lung biopsy, ventilation, CVP line insertion), trauma (associated with rib fractures), emphysema, malignancy, honeycomb lung
- management: needle decompression or chest tube insertion, repeat CXR to ensure resolution

Asbestos

- asbestos exposure may cause various pleural abnormalities including benign plaques (most common; these may calcify), diffuse pleural fibrosis, effusion, and malignant mesothelioma

Figure 13. Pneumothorax

Elevated Hemidiaphragm Suggests

PAL DIP

- Pregnancy
- Atelectasis
- Lung resection
- Diaphragmatic paralysis
- Intra-abdominal process
- Pneumectomy
- Pleural effusion also may result in apparent elevation

Depressed Hemidiaphragm Suggests

TALC

- Tumour
- Asthma
- Large pleural effusion
- COPD

DDx Anterior Mediastinal Mass

4 Ts

- Thyroid
- Thymic neoplasm
- Teratoma
- Terrible lymphoma

Figure 14. Lateral CXR showing four mediastinal compartments

Mediastinal Abnormalities

Mediastinal Mass

- the mediastinum is divided into four compartments; this provides an approach to the differential diagnosis of a mediastinal mass
- anterior border formed by the sternum and posterior border by the heart and great vessels
 - 4 Ts: see sidebar
 - cardiophrenic angle mass differential: thymic cyst, epicardial fat pad, foramen of Morgagni hernia
- middle border (extending behind anterior mediastinum to a line 1 cm posterior to the anterior border of the thoracic vertebral bodies)
 - esophageal carcinoma, esophageal duplication cyst, metastatic disease, lymphadenopathy (all causes), hiatus hernia, bronchogenic cyst
- posterior border (posterior to the middle line described above)
 - neurogenic tumour (e.g. neurofibroma, schwannoma), multiple myeloma, pheochromocytoma, neuroenteric cyst, thoracic duct cyst, lateral meningocele, Bochdalek hernia, extramedullary hematopoiesis
- superior boundaries (superiorly by thoracic inlet, inferiorly by plane of the sternal angle, anteriorly by manubrium, posteriorly by T1-T4, laterally by pleura)
- in addition, any compartment may give rise to lymphoma, lung cancer, aortic aneurysm or other vascular abnormalities, abscess, or hematoma

Enlarged Cardiac Silhouette

- heart borders
 - on PA view, right heart border is formed by right atrium; left heart border is formed by left atrium and left ventricle
 - on lateral view, anterior heart border is formed by right ventricle; posterior border is formed by left atrium (superior to left ventricle) and left ventricle
- cardiothoracic ratio = greatest transverse dimension of the central shadow relative to the greatest transverse dimension of the thoracic cavity
 - using a good quality erect PA chest film in adults, cardiothoracic ratio of >0.5 is abnormal
 - differential of ratio >0.5
 - ♦ cardiomegaly (myocardial dilatation or hypertrophy)
 - ♦ pericardial effusion
 - ♦ poor inspiratory effort/low lung volumes
 - ♦ pectus excavatum
- ratio <0.5 does not exclude enlargement (e.g. cardiomegaly + concomitant hyperinflation)
- pericardial effusion: globular heart with loss of indentations on left mediastinal border
- RA enlargement: increase in curvature of right heart border and enlargement of SVC
- LA enlargement: straightening of left heart border; increased opacity of lower right side of cardiovascular shadow (double heart border); elevation of left main bronchus (specifically, the upper lobe bronchus on the lateral film), distance between left main bronchus and “double” heart border >7 cm, splayed carina (late sign)
- RV enlargement: elevation of cardiac apex from diaphragm; anterior enlargement leading to loss of retrosternal air space on lateral; increased contact of right ventricle against sternum
- LV enlargement: rounding of the cardiac apex; displacement of left cardiac boarder leftward, inferiorly, and posteriorly

Tubes, Lines, and Catheters

- ensure appropriate placement and assess potential complications of lines and tubes
- avoid mistaking a line/tube for pathology (e.g. oxygen rebreather mask for pneumothoraces)

Central Venous Catheter

- used for fluid and medication administration, vascular access for hemodialysis, and CVP monitoring
- tip must be located proximal to right atrium to prevent inducing arrhythmias or perforating wall of atrium
 - if monitoring CVP, catheter tip must be proximal to venous valves
- tip of well-positioned central venous catheter projects over silhouette of SVC in a zone demarcated superiorly by the anterior first rib end and clavicle, and inferiorly by top of RA
- course should parallel course of SVC; if appears to bend as it approaches wall of SVC or appears perpendicular, catheter may damage and ultimately perforate wall of SVC
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

Figure 15. CXR showing well-positioned central venous catheter

Endotracheal Tube

- frontal chest film: tube projects over trachea and shallow oblique or lateral chest radiograph will help determine position in 3 dimensions
- progressive gaseous distention of stomach on repeat imaging is concerning for esophageal intubation
- tip should be located 4 cm above tracheal carina (avoids bronchus intubation and vocal cord irritation)
- maximum inflation diameter <3 cm to avoid necrosis of tracheal mucosa and rupture; ensure diameter of balloon is less than tracheal diameter above and below balloon
- complications: aspiration (parenchymal opacities), pharyngeal perforation (subcutaneous emphysema, pneumomediastinum, mediastinitis)

Nasogastric Tube

- tip and sideport should be positioned distal to esophagogastric junction and proximal to gastric pylorus
- radiographic confirmation of tube is mandatory because clinical techniques for assessing tip position may be unreliable
- complications: aspiration (parenchymal opacities), intracranial perforation (trauma patients), pneumothorax

Swan-Ganz Catheter

- to monitor pulmonary capillary wedge pressure and to measure cardiac output for suspected LV dysfunction
- tip should be positioned within right or left main pulmonary arteries or in one of their large, lobar branches
- if tip is located more distally, increased risk of prolonged pulmonary artery occlusion resulting in pulmonary infarction or, rarely, pulmonary artery rupture
- complications: pneumothorax, bleeding (mediastinal, pleural), air embolism

Chest Tube

- in dorsal and caudal portion of pleural space to evacuate fluid
- in ventral and cephalad portions of pleural space to evacuate pneumothoraces
- tube may lie in fissure as long as functioning
- complications: lung perforation (mediastinal opacities)

Abdominal Imaging

Abdominal X-Ray

Indications

- acute abdomen: bowel perforation, toxic megacolon, bowel ischemia, small bowel obstruction, large bowel obstruction
- chronic symptoms: constipation, calcifications (gallstones, renal stones, urinary bladder stones, etc.)
- not useful in: GI bleeds, chronic anemia, vague GI symptoms

Anatomy

- abdomen divided into 2 cavities
 - peritoneal cavity: lined by peritoneum that wraps around most of the bowel, the spleen, and most of the liver; forms a recess lateral to both the ascending and descending colon (paracolic gutters)
 - retroperitoneal cavity: contains several organs situated posterior to the peritoneal cavity; the contour of these can often be seen on radiographs

3 Views of AXR

- Erect/Upright
- Supine
- Left lateral decubitus

Table 7. Differentiating Small and Large Bowel

Property	Small Bowel	Large Bowel
Mucosal Folds	Uninterrupted valvulae conniventes (or plicae circularis)	Interrupted haustra extend only partway across lumen
Location	Central	Peripheral (picture frame)
Maximum Diameter	3 cm	6 cm (9 cm at cecum)
Maximum Fold Thickness	3 mm	5 mm
Other	Rarely contains solid fecal material	Commonly contains solid fecal material

3-6-9 Rule of Dilation
 Small bowel (>3 cm)
 Large bowel (>6 cm)
 Cecum (>9 cm)

Approach to Abdominal X-Ray

- mnemonic: “Free ABDO”
- “Free”: free air and fluid
 - free fluid
 - ♦ small amounts of fluid: increased distance between lateral fat stripes and adjacent colon may indicate free peritoneal fluid in the paracolic gutters
 - ♦ large amounts of fluid: diffuse increased opacification on supine film; bowel floats to centre of anterior abdominal wall
 - ♦ ascites and blood (hemoperitoneum) are the same density on the radiograph, and therefore, cannot be differentiated
 - ♦ free intraperitoneal air suggests rupture of a hollow viscus (anterior duodenum, transverse colon), penetrating trauma, or recent (<7 d) surgery
- “A”: air in the bowel (can be normal, ileus, or obstruction)
 - volvulus – twisting of the bowel upon itself; from most to least common:
 - ♦ sigmoid: “coffee bean” sign (massively dilated sigmoid projects to right or mid-upper abdomen) with proximal dilation
 - ♦ cecal: massively dilated bowel loop projecting to left or mid-upper abdomen with small bowel dilation
 - ♦ gastric: rare
 - ♦ transverse colon: rare (usually young individuals)
 - ♦ small bowel: “corkscrew sign” (rarely diagnosed on plain films, seen best on CT)
 - toxic megacolon
 - ♦ manifestation of fulminant colitis
 - ♦ extreme dilatation of colon (>6.5 cm) with mucosal changes (e.g. foci of edema, ulceration, pseudopolyps), loss of normal haustral pattern
- “B”: bowel wall thickening
 - increased soft tissue density in bowel wall, thumb-like indentations in bowel wall (“thumb-printing”), or a picket-fence appearance of the valvulae conniventes (“stacked coin” appearance)
 - may be seen in IBD, infection, ischemia, hypoproteinemic states, and submucosal hemorrhage
- “D”: densities
 - bones: look for gross abnormalities of lower ribs, vertebral column, and bony pelvis
 - abnormal calcifications: approach by location
 - ♦ RUQ: renal stone, adrenal calcification, gallstone, porcelain gallbladder
 - ♦ RLQ: ureteral stone, appendicolith, gallstone ileus
 - ♦ LUQ: renal stone, adrenal calcification, tail of pancreas
 - ♦ LLQ: ureteral stone
 - ♦ central: aorta/aortic aneurysm, pancreas, lymph nodes
 - ♦ pelvis: phleboliths (i.e. calcified veins), uterine fibroids, bladder stones
- “O”: organs
 - kidney, liver, gallbladder, spleen, pancreas, urinary bladder, psoas shadow
 - outlines can occasionally be identified because they are surrounded by more lucent fat, but all are best visualized with other imaging modalities (CT, MRI)

Figure 16. Normal AXRs: (left) supine anteroposterior AXR, (middle) upright anteroposterior AXR, and (right) left lateral decubitus AXR

Table 8. Abnormal Air on Abdominal X-Ray

Air	Appearance	Common Etiologies
Extraluminal Intraperitoneal (pneumoperitoneum)	Upright film: air under diaphragm Left lateral decubitus film: air between liver and abdominal wall Supine film: gas outlines of structures not normally seen: Inner and outer bowel wall (Rigler's sign) Falciform ligament Peritoneal cavity ("football" sign)	Perforated viscus Post-operative (up to 10 d to be resorbed)
Retroperitoneal	Gas outlining retroperitoneal structures allowing increased visualization: Psoas shadows Renal shadows	Perforation of retroperitoneal segments of bowel: duodenal ulcer, post-colonoscopy
Intramural (pneumatosis intestinalis)	Lucent air streaks in bowel wall, 2 types: 1. Linear 2. Rounded (cystoides type)	1. Linear: ischemia, necrotizing enterocolitis 2. Rounded/cystoides (generally benign): primary (idiopathic), secondary to COPD
Intraluminal	Dilated loops of bowel, air-fluid levels	Adynamic (paralytic) ileus, mechanical bowel obstruction
Loculated	Mottled, localized in abnormal position without normal bowel features	Abscess (evaluate with CT)
Biliary	Air centrally over liver	Sphincterotomy, gallstone ileus, erosive peptic ulcer, cholangitis, emphysematous cholecystitis
Portal Venous	Air peripherally over liver in branching pattern	Bowel ischemia/infarction

**Biliary vs. Portal Venous Air**

"Go with the flow": air follows the flow of bile or portal venous blood
Biliary air is most prominent centrally over the liver
Portal venous air is most prominent peripherally

Table 9. Adynamic Ileus vs. Mechanical Obstruction

Feature	Adynamic Ileus	Mechanical Obstruction
Calibre of Bowel Loops	Normal or dilated	Usually dilated
Air-Fluid Levels (erect and left lateral decubitus films only)	Same level in the same single loop	Multiple air fluid levels giving "step ladder" appearance, dynamic (indicating peristalsis present), "string of pearls" (row of small gas accumulations in the dilated valvulae conniventes)
Distribution of Bowel Gas	Air throughout GI tract is generalized or localized In a localized ileus (e.g. pancreatitis, appendicitis), dilated "sentinel loop" remains in the same location on serial films, usually adjacent to the area of inflammation	Dilated bowel up to the point of obstruction (i.e. transition point) No air distal to obstructed segment "Hairpin" (180°) turns in bowel

Abdominal Computed Tomography

- indications for plain CT: renal colic, hemorrhage
- indications for CT with contrast
 - IV contrast given immediately before or during CT to allow identification of arteries and veins
 - portal venous phase: indicated for majority of cases
 - biphasic (arterial and portal venous phases): liver, pancreas, bile duct tumours
 - caution: contrast allergy (may premedicate with steroids and antihistamine)
 - contraindication: impaired renal function (based on eGFR)
 - oral contrast: barium or water-soluble (water soluble if suspected perforation) given in most cases to demarcate GI tract
 - rectal contrast: given for investigation of colonic lesions

Approach to Abdominal Computed Tomography

- look through all images in gestalt fashion to identify any obvious abnormalities
- look at each organ/structure individually, from top to bottom, evaluating size and shape of each area of increased or decreased density
- evaluate the following:
 - soft tissue window
 - liver, gallbladder, spleen, and pancreas
 - adrenals, kidneys, ureters, and bladder
 - stomach, duodenum, small bowel mesentery, and colon/appendix
 - retroperitoneum: aorta, vena cava, and mesenteric vessels; look for adenopathy in vicinity of vessels
 - peritoneal cavity for fluid or masses
 - abdominal wall and adjacent soft tissue
 - lung window
 - visible lung (bases)
 - bone window
 - vertebrae, spinal cord, and bony pelvis

Colorectal Cancer: CT Colonography and Colonoscopy for Detection-Systematic Review and Meta-Analysis

Radiology 2011;259:393-405

Purpose: To assess the sensitivity of computed tomography (CT) colonography and optical colonoscopy (OC) for colorectal cancer (CRC) detection.

Methods: Systematic review and meta-analysis of diagnostic studies evaluating CT colonography detection of CRC based on a priori eligibility criteria, in particular requiring both OC and histological confirmation of disease. Studies that also assessed true-positive and false-negative diagnoses with OC were used to calculate OC sensitivity. Sensitivity of CTC and OC for CRC was the main outcome.

Results: 49 studies on 11,151 patients undergoing diagnostic study for detection of CRC were included. CTC has a sensitivity of 96.1% (95% CI 93.8%, 97.7%) and OC has a sensitivity of 94.7% (95% CI 90.4%, 97.2%) for the detection of CRC.

Conclusion: CTC is highly sensitive for the detection of CRC and may be a better modality for the initial investigation of suspected CRC, assuming reasonable specificity.

Figure 17. Axial abdominal computed tomography

CT and Bowel Obstruction

- cause of bowel obstruction rarely found on plain films; CT is best choice for imaging
- the “3,6,9” rule is a very useful guide to determining when the bowel is dilated; the maximum diameter of the bowel is 3 cm for small bowel, 6 cm for large bowel, and 9 cm for cecum; this can also be useful to distinguish small and large bowel, and to assess for ‘impending’ cecal perforation (e.g. post-untreated Ogilvie’s syndrome)
- closed-loop obstruction: an obstruction in two locations (usually small bowel) creating a loop of bowel segment obstructed both proximally and distally; complications (e.g. ischemia, perforation, necrosis) may occur quickly

CT Colonography (virtual colonoscopy)

- emerging imaging technique for evaluation of intraluminal colonic masses (i.e. polyps, tumours)
- two CT scans of the abdomen (prone and supine) after the instillation of carbon dioxide into a prepped colon
- computer reconstruction of 2D CT images into a 3D intraluminal view of the colon
- lesions seen on 3D images correlated with 2D axial images
- indications: surveillance in low-risk patients, incomplete colonoscopy, staging of obstructing colonic lesions

Contrast Studies

Table 10. Types of Contrast Studies

Study	Organ	Procedure Description	Assessment	Findings
Cine Esophagogram	Cervical esophagus	Contrast agent swallowed Recorded for later playback and analysis	Dysphagia, swallowing incoordination, recurrent aspiration, post-operative cleft palate repair	Aspiration, webs (partial occlusion), Zenker’s diverticulum, cricopharyngeal bar, laryngeal tumour
Barium Swallow	Thoracic esophagus	Contrast agent swallowed under fluoroscopy, selective images captured	Dysphagia, rule out GERD, post-esophageal surgery	Achalasia, hiatus hernia, esophagitis, cancer, esophageal tear
Upper GI Series	Thoracic esophagus, stomach, and duodenum	Double contrast study: 1. Barium to coat mucosa, then 2. Gas pills for distention Patient NPO after midnight	Dyspepsia, investigate possible upper GI bleed, weight loss/anemia, post-gastric surgery	Ulcers, neoplasms, filling defects
Enterography and Enteroclysis (MRI or CT)	Entire small bowel	Enterography: patient drinks 1-2 L of sorbitol, psyllium, or barium solution to distend small bowel Enteroclysis: NJ tube used to pump barium, psyllium, or sorbitol contrast media directly into small bowel	IBD, malabsorption, weight loss/anemia, Meckel’s diverticulum	Neoplasms, IBD, malabsorption, infection

Specific Visceral Organ Imaging

Liver

- U/S: assessment of cysts, abscesses, tumours, biliary tree
- CT ± IV: most popular procedure for imaging the liver parenchyma (primary liver tumours, metastases, cysts, abscesses, trauma, cirrhosis)
- MR: also excellent in evaluation of primary liver tumours, liver metastases, and other parenchymal conditions, and is particularly helpful in differentiating common benign hepatic hemangiomas from primary liver tumours and metastases
- elastography: measures shear wave velocity by U/S (Fibroscan) or MRI (MR elastography) to non-invasively quantify liver fibrosis
- findings
 - advanced cirrhosis: liver small and irregular (fibrous scarring, segmental atrophy, regenerating nodules)
 - portal HTN: increased portal vein diameter, collateral veins, splenomegaly (≥ 12 cm), portal vein thrombosis, recanalization of the umbilical vein
 - porto-systemic shunts: caput medusa, esophageal varices, spontaneous spleno-renal shunt
 - U/S: cirrhosis appears nodular and hyperechoic with irregular areas of atrophy of the right lobe and hypertrophy of the caudate or left lobes
 - CT: fatty infiltration appears hypodense
- in order to be visualized, some masses require contrast
- upon identifying a liver lesion on imaging (e.g. U/S), the follow-up imaging modality should be CT or MR. CT would be four-phase non-contrast, arterial, venous, and delayed to distinguish the common benign liver lesion hemangioma from other tumours

Normal liver appears denser than spleen on CT. If less dense, suspect fatty infiltration

Liver Mass DDX

- 5 Hs
- HCC
- Hydatid cyst
- Hemangioma
- Hepatic adenoma
- Hyperplasia (focal nodular)

Table 11. Imaging of Liver Masses

Mass	U/S	CT
Benign		
Hepatic Adenoma	Most common in young women taking oral contraceptives. Well-defined mass with hyperechoic areas due to hemorrhage	Well-defined hypervascular lesion with enlarged central vessel becoming slightly isoattenuating in venous phase
Hemangioma	Homogeneous hyperechoic mass	Peripheral globular enhancement in arterial phase scans; central filling and persistent enhancement on delayed scans
Focal Nodular Hyperplasia	Well-defined mass, central scar seen in 50%	Hypervascular mass in arterial phase and isoattenuation to liver in portal venous phase
Abscess	Ill-defined, irregular margin, hypoechoic contents	Low attenuation lesion with an irregular enhancing wall
Hydatid Cyst	Simple/multiloculated cyst	Low attenuation simple or multiloculated cyst; calcification
Malignant		
HCC	Single/multiple masses, or diffuse infiltration	Hypervascular; enhances in arterial and washes out in venous phase with portal venous tumour thrombus
Metastases	Multiple masses of variable echotexture	Usually low attenuation on contrast-enhanced scan

Spleen

- U/S, CT, nuclear medicine scan (nuclear medicine only to distinguish ectopic splenic tissue from enhancing tumours)
- CT for splenic trauma (hemorrhage)

Pancreas

- tumours
 - U/S: mass is more echogenic than normal pancreatic tissue
 - CT: preferred modality for diagnosis/staging
- ductal dilation secondary to stone/tumour
 - MRCP: imaging of ductal system using MRI cholangiography; no therapeutic potential
 - ERCP: endoscope to inject dye into the biliary tree and x-ray imaging to assess pancreatic and biliary ducts; therapeutic potential (stent placement, stone retrieval); acute pancreatitis is a complication in 5% of diagnostic procedures and 10% of therapeutic procedures

Biliary Tree

- U/S: bile ducts usually visualized only if dilated, secondary to obstruction (e.g. choledocholithiasis, benign stricture, mass)
- CT: dilated intrahepatic ductules seen as branching, tubular structures following pathway of portal venous system
- MRCP, ERCP, PTC: further evaluation of obstruction and possible intervention

Revised Estimates of Diagnostic Test Sensitivity and Specificity in Suspected Biliary Tract Disease

Arch Intern Med 1998;154:2573-2581

Purpose: To assess the sensitivity and specificity of tests used to diagnose cholelithiasis and acute cholecystitis, including ultrasonography (U/S), oral cholecystography, radionuclide scanning with Technetium, magnetic resonance imaging (MRI) or computed tomography (CT).

Methods: Meta-analysis of studies evaluating the use of different imaging modalities in the diagnosis of biliary tract disease. Main outcomes were sensitivity and specificity of the different imaging modalities, using the gold standard of surgery, autopsy, or 3 mo clinical follow-up for cholelithiasis. For acute cholecystitis, pathologic findings, confirmation of an alternate disease, or clinical resolution during hospitalization for cholecystitis were used as the standard.

Results: Thirty studies were included. For evaluating cholelithiasis, U/S had the best unadjusted sensitivity (0.97; 95% CI 0.95-0.99) and specificity (0.95, 0.88-1.00) and adjusted (for verification bias) sensitivity (0.84; 0.76-0.92) and specificity (0.99; 95% CI 0.97-1.00). For evaluating acute cholecystitis, radionuclide scanning has the best sensitivity (0.97; 0.96-0.98) and specificity (0.90; 0.86-0.95).

Conclusion: U/S is the test of choice for diagnosing cholelithiasis and radionuclide scanning is the superior test for diagnosing acute cholecystitis.

Figure 18. ERCP: biliary tree

"itis" Imaging

Acute Cholecystitis

- pathogenesis: inflammation of gallbladder resulting from sustained gallstone impaction in cystic duct or, in the case of acalculous cholecystitis, due to gallbladder ischemia or cholestasis (see [General Surgery, GS47](#))
- best imaging modality: U/S (best sensitivity and specificity); nuclear medicine (HIDA scan) can help diagnose cases of acalculous or chronic cholecystitis
- findings: Most sensitive findings are presence of gallstones and positive sonographic Murphy's sign (tenderness from pressure of US probe over visualized gallbladder). Secondary findings include thickened gallbladder wall (>3 mm), dilated gallbladder and pericholecystic fluid.
- management: admit, NPO, IVF, analgesia, cefazolin, early laparoscopic cholecystectomy

Acute Appendicitis

- pathogenesis: luminal obstruction → bacterial overgrowth → inflammation/swelling → increased pressure → localized ischemia → gangrene/perforation → localized abscess or peritonitis (see [General Surgery, GS27](#))
- best imaging modality: U/S or CT
- findings
 - U/S: thick-walled appendix, appendicolith, dilated fluid-filled appendix, non-compressible; may also demonstrate other causes of RLQ pain (e.g. ovarian abscess, IBD, ectopic pregnancy)
 - CT: enlargement of appendix (>6 mm in outer diameter), enhancement of appendiceal wall, adjacent inflammatory stranding, appendicolith; also facilitates percutaneous abscess drainage
- management: admit, NPO, IVF, analgesia, cefazolin + metronidazole, appendectomy

Acute Diverticulitis

- pathogenesis: erosion of the intestinal wall (most commonly rectosigmoid) by increased intraluminal pressure or inspissated food particles → inflammation and focal necrosis → micro- or macroscopic perforation (see [General Surgery, GS31](#))
- best imaging modality: CT, although U/S is sometimes used
- contrast: oral and rectal contrast given before CT to opacify bowel
- findings
 - cardinal signs: thickened wall, mesenteric infiltration, gas-filled diverticula, abscess
 - CT can be used for percutaneous abscess drainage before or in lieu of surgical intervention
 - sometimes difficult to distinguish from perforated cancer (therefore send abscess fluid for cytology and follow-up with colonoscopy)
 - if chronic, may see fistula (most common to bladder) or sinus tract (linear or branching structures)
- management: ranges from antibiotic treatment to surgical intervention; can use imaging to follow progression

Acute Pancreatitis

- pathogenesis: activation of proteolytic enzymes within pancreatic cells leading to local and systemic inflammatory response (see [Gastroenterology, G44](#)); a clinical/biochemical diagnosis
- best imaging modality: imaging used to support diagnosis and evaluate for complications (diagnosis cannot be excluded by imaging alone)
 - U/S good for screening and follow-up
 - CT is useful in advanced stages and in assessing for complications (1st line imaging test)
- findings
 - U/S: hypoechoic enlarged pancreas (if ileus present, gas obscures pancreas)
 - CT: enlarged pancreas, edema, stranding changes in surrounding fat with indistinct fat planes, mesenteric and Gerota's fascia thickening, pseudocyst in lesser sac, abscess (gas or thick-walled fluid collection), pancreatic necrosis (low attenuation gas-containing non-enhancing pancreatic tissue), hemorrhage
- management: supportive therapy
 - CT-guided needle aspiration and/or drainage done for abscess when clinically indicated
 - pseudocyst may be followed by CT and drained if symptomatic

Chronic Pancreatitis

- pathogenesis: (see [Gastroenterology, G45](#))
- best imaging modality: MRCP (can show calcification and duct obstruction)
- findings: U/S, CT scan, and MRI can show calcifications, ductal dilatation, enlargement of the pancreas and fluid collections (e.g. pseudocysts) adjacent to the gland

Figure 19. Ultrasound: inflamed gallbladder

Figure 20. Ultrasound: inflamed appendix

Computed Tomography and Ultrasonography to Detect Acute Appendicitis in Adults and Adolescents

Ann Intern Med 2004;141:537-546

Purpose: To review the diagnostic accuracy of computed tomography (CT) and ultrasonography (U/S) in the diagnosis of acute appendicitis.

Methods: Meta-analysis of prospective studies evaluating the use of CT or U/S, followed by surgical or clinical follow-up in patients with suspected appendicitis. Patients aged ≥14 years with a clinical suspicion of appendicitis were eligible. Sensitivity and specificity using surgery or clinical follow-up as the gold standard were the main outcomes studied.

Results: Twenty-two studies were included. CT (12 studies) had an overall sensitivity of 0.94 (95% CI 0.91-0.95) and a specificity of 0.95 (0.93-0.96). U/S (14 studies) had an overall sensitivity of 0.86 (0.83-0.88) and a specificity of 0.81 (0.78-0.84).

Conclusion: CT is more accurate for diagnosing appendicitis in adults and adolescents, although verification bias and inappropriate blinding of reference standards were noted in the included studies.

Angiography of Gastrointestinal Tract

- anatomy of the GI tract arterial blood supply branches
 - celiac artery: hepatic, splenic, gastroduodenal, left/right gastric
 - superior mesenteric artery: jejunal, ileal, ileo-colic, right colic, middle colic
 - inferior mesenteric artery: left colic, superior rectal
- imaging modalities
 - conventional angiogram: invasive (usual approach via femoral puncture), catheter used
 - ♦ flush aortography: catheter injection into abdominal aorta, followed by selective arteriography of individual vessels
 - CT angiogram: modality of choice, non-invasive using IV contrast (no catheterization required)

Angiography requires active blood loss
 1-1.5 mL/min under optimal conditions for a bleeding site to be visualized in cases of lower GI bleeding

Genitourinary System and Adrenal

Urological Imaging

KUB (Kidney, Ureter, and Bladder X-ray)

- a frontal supine radiograph of the abdomen
- indication: useful in evaluation of radio-opaque renal stones (all stones but uric acid and indinavir), indwelling ureteric stents/catheters, and foreign bodies in abdomen
- findings: addition of IV contrast excreted by the kidney (intravenous urogram) allows greater visualization of the urinary tract, but has been largely replaced by CT urography

Abdominal CT

Renal Masses

- Bosniak classification for cystic renal masses
- class I-II: benign and can be disregarded
- class IIF: should be followed
- class III-IV: suspicious for malignancy, requiring additional workup

Table 12. Bosniak Classification for Cystic Renal Masses

Classes	Definition
Simple Renal Cysts	
Class I	Fluid-attenuating well-defined lesion, no septation, no calcification, no solid components, hair thin wall
Class II	Same as class I + fine calcification or moderately thickened calcification in septae or walls; also includes hyperdense cysts (<3 cm) that do not enhance with contrast
Complex Renal Cysts	
Class III	Thick irregular walls ± calcifications ± septated, enhancing walls or septa with contrast
Renal Cell Carcinoma	
Class IV	Same as class III + soft tissue enhancement with contrast (defined as >10 Hounsfield unit increase, characterizing vascularity) with de-enhancement in venous phase ± areas of necrosis

- plain CT KUB indications: general imaging of renal anatomy, renal colic symptoms, assessment of renal calculi (size and location), and hydronephrosis prior to urological treatment
- CT urography indications: investigation of cause of microscopic/gross hematuria, detailed assessment of urinary tracts (excretory phase), high sensitivity (95%) for uroepithelial malignancies of the upper urinary tracts, assessment of renal calculi
 - phases: unenhanced, excretory
- renal triphasic CT indications: standard imaging for renal masses, allows accurate assessment of renal arteries and veins, better characterization of suspicious renal masses, especially in differentiating renal cell carcinoma from more benign masses, and pre-operative staging
 - phases: unenhanced, arterial and venous (nephrographic), excretory

Ultrasound

- **indications:** initial study for evaluation of kidney size and nature of renal masses (solid vs. cystic renal masses vs. complicated cysts); technique of choice for screening patients with suspected hydronephrosis (no IV contrast injection, no radiation to patient, and can be used in patients with renal failure); TRUS useful to evaluate prostate gland and guide biopsies; Doppler U/S to assess renal vasculature
- **findings:** solid renal masses are echogenic (bright on U/S), cystic renal masses have smooth well-defined walls with anechoic interior (dark on U/S), and complicated cysts have internal echoes within a thickened, irregular wall

Imaging Modality Based on Presentation

- Acute testicular pain = Doppler, U/S
- Amenorrhea = U/S, MRI (brain)
- Bloating = U/S, CT
- Flank pain = U/S, CT
- Hematuria = U/S, Cystoscopy, CT
- Infertility = HSG, MRI
- Lower abdominal mass = U/S, CT
- Lower abdominal pain = U/S, CT
- Renal colic = U/S, KUB, CT
- Testicular mass = U/S
- Urethral stricture = Urethrogram

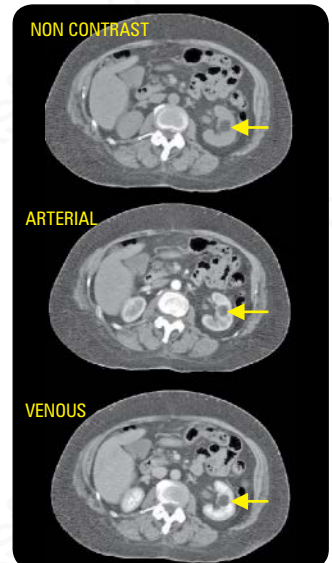

Figure 21. Triphasic CT of an angiomyolipoma: showing fat density with non-contrast scan, mildly enhancing with contrast

Retrograde Pyelography

- **indications:** visualize the urinary collecting system via a cystoscope, ureteral catheterization, and retrograde injection of contrast medium, visualized by radiograph or fluoroscopy; ordered when the intrarenal collecting system and ureters cannot be opacified using intravenous techniques (patient with impaired renal function, high grade obstruction)
- **findings:** only yields information about the collecting systems (renal pelvis and associated structures), no information regarding the parenchyma of the kidney

Voiding Cystourethrogram

- bladder filled with contrast to the point where voiding is triggered
- fluoroscopy (continuous, real-time) to visualize bladder
- indications: children with recurrent UTIs, hydronephrosis, hydroureter, suspected lower urinary tract obstruction or vesicoureteral reflux
- findings: contractility and evidence of vesicoureteric reflux

Retrograde Urethrogram

- a small Foley catheter placed into penile urethral opening
- indications: used mainly to study strictures or trauma to the male urethra; first-line study if trauma with blood present at urethral meatus

MRI

- **advantages:** high spatial and tissue resolution, lack of exposure to ionizing radiation and nephrotoxic contrast agents
- **indications:** indicated over CT for depiction of renal masses in patients with previous nephron-sparing surgery, patients requiring serial follow-up (less radiation dosage), patients with reduced renal function, patients with solitary kidneys, clinical staging of prostate cancer (endorectal coil MRI)

Renal Nuclear Scan

Table 13. Renal Scan Tests

Type of Test	Uses	Radionuclide
Renogram	Assess renal function and collecting system: evaluation of renal failure, workup of urinary tract obstruction and renovascular HTN, investigation of renal transplant	IV ^{99m}Tc -pentetate (DTPA) or mertiatide (MAG3), and imaged at 1-3 s intervals with a gamma camera over the first 60 s to assess perfusion
Morphological	Assess renal anatomy: investigation of pyelonephritis and cortical scars	^{99m}Tc -DMSA ^{99m}Tc -glucoheptonate

Figure 22. Triphasic CT of a renal cell carcinoma: showing arterial enhancing right renal lesion with venous washout (shunting)

Figure 23. Retrograde urethrogram: demonstrating stricture in the membranous urethra

Figure 24. Transabdominal U/S: pregnancy, 18 wk fetus

Pregnancy should always be ruled out by β -hCG before CT of a female pelvis (or any organ system) is performed

Figure 25. Hysterosalpingogram: left hydrosalpinx

Gynecological Imaging

Ultrasound

- transabdominal and transvaginal are the primary modalities, and are indicated for different scenarios
- transabdominal requires a full bladder to push out air-containing loops of bowel
 - indications: good initial investigation for suspected pelvic pathology
- TVUS provides enhanced detail of deeper/smaller structures by allowing use of higher frequency sound waves at reduced distances
 - indications: improved assessment of ovaries, first trimester development, and ectopic pregnancies

Hysterosalpingogram

- performed by x-ray images of the pelvis after cannulation of the cervix and subsequent injection of opacifying agent
- **indications:** useful for assessing pathology of the uterine cavity and fallopian tubes, evaluating uterine abnormalities (e.g. bicornuate uterus), or evaluation of fertility (absence of flow from tubes to peritoneal cavity indicates obstruction)

CT/MRI

- **indications:** evaluating pelvic structures, especially those adjacent to the adnexa and uterus
- invaluable for staging gynecological malignancies and detecting recurrence

Sonohysterogram

- saline infusion sonohysterogram involves injecting fluid into the uterine cavity transcervically to provide enhanced endometrial visualization during TVUS examination
- indications: abnormal uterine bleeding, uterine cavity abnormalities that are suspected or noted on TVUS (e.g. leiomyomas, polyps, synechiae), congenital abnormalities of the uterine cavity, infertility, recurrent pregnancy loss
- contraindications: pregnancy, pelvic infection

Table 14. Typical and Atypical Findings on a Sonohysterogram

Finding	Typical	Atypical
Polyps	A well-defined, homogeneous, polypoid lesion isoechoic to the endometrium with preservation of the endometrial-myometrial interface	Atypical features include cystic components, multiple polyps, broad base, hypoechogenicity or heterogeneity
Leiomyoma	Well-defined, broad-based, hypoechoic, solid masses with shadowing. Overlying layer of endometrium is echogenic and distorts the endometrial-myometrial interface	Pedunculation or multilobulated surface
Hyperplasia and Cancer	Diffuse echogenic endometrial thickening without focal abnormality, although focal lesions can occur. Endometrial cancer is typically a diffuse process, but early cases can be focal and appear as a polypoid mass	
Adhesions	Mobile, thin, echogenic bands that cut across the endometrial cavity	Thick, broad-based bands that can completely obliterate the endometrial cavity, as in Asherman's syndrome

Modality Based on Neuropathology Presentation

- Cognitive decline = CT
- Cord compression = MRI
- Decreased level of consciousness = CT
- Fish bone/other swallowed foreign body = CT
- Low back pain, radiculopathy = MRI
- Multiple sclerosis = MRI
- Neck infection = CT
- Orbital infection = CT
- Rule out bleed = CT
- Rule out aneurysm = CTA, MRA
- Seizure = CT
- Sinusitis = CT
- Stroke = CT, MRI
- Trauma = CT
- Weakness, systemically unwell = CT

Adrenal Mass

- imaging modality: most often identified on CT scan as 'incidentaloma,' can also use CT/MRI to distinguish benign from malignant masses

Table 15. Adrenal Mass Findings on CT and MRI

Factors	Adrenocortical Adenoma	Adrenocortical Carcinoma	Pheochromocytoma	Metastasis
Diameter (CT)	Usually ≤ 3 cm	Usually ≥ 4 cm	Usually > 3 cm	Variable around < 3 cm
Shape (CT)	Smooth margins and round/oval	Irregular with unclear margins	Round/oval with clear margins	Oval/irregular with unclear margins
Texture (CT)	Homogeneous	Heterogeneous with mixed densities	Heterogeneous with cystic areas	Heterogeneous with mixed densities
Vascularity (CT)	Not highly vascular	Usually vascular	Usually vascular	Usually vascular
Washout of Contrast Medium on CT	$\geq 50\%$ at 10 min	$< 50\%$ at 10 min	$< 50\%$ at 10 min	$< 50\%$ at 10 min
Growth	Stable or very slow (< 1 cm/yr)	Usually rapid (> 2 cm/yr)	Slow (0.5-1 cm/yr)	Variable
Other Findings	Usually low density due to intracellular fat	Necrosis, calcifications, and hemorrhage	Hemorrhage	Occasionally hemorrhage
MRI on T2 Weighted Imaging	Isointense in relation to liver	Hyperintense in relation to liver	Markedly hyperintense in relation to liver	Hyperintense in relation to liver

Neuroradiology

Modalities

- CT is the modality of choice for most neuropathology; even under circumstances where MRI is preferred, CT is frequently the initial study performed because of its speed, availability, and lower cost
 - acute head trauma: CT is best for visualizing "bone and blood"; MRI is used only when CT fails to detect an abnormality despite strong clinical suspicion
 - acute stroke: MRI ideal, CT most frequently used
 - suspected subarachnoid or intracranial hemorrhage
 - meningitis: rule out mass effect (e.g. cerebral herniation, shift) prior to lumbar puncture
 - tinnitus and vertigo: CT and MRI are used in combination to detect bony abnormalities and CN VIII tumours, respectively

Skull Films

- rarely performed, generally not indicated for non-penetrating head trauma
- indications: screening for destructive bony lesions (e.g. metastases), metabolic disease, skull anomalies, post-operative changes and confirmation of hardware placement, skeletal surveys, multiple myeloma

CT

- **indications:** excellent study for evaluation of bony and intracranial abnormalities
- often done first without and then with IV contrast to show vascular structures or anomalies
- vascular structures and areas of blood-brain barrier impairment are opaque (e.g. hyperattenuating or white/show enhancement) with contrast injection
 - when in doubt, look for Circle of Willis or confluence of sinuses to determine presence of contrast enhancement

Figure 26. Epidural hematoma

Figure 27. Subdural hematoma

Figure 28. Subarachnoid hemorrhage

Figure 29. Intraparenchymal hemorrhage

- posterior fossa can be obscured by extensive bony-related streak artifact
- rule out skull fracture, epidural hematoma (lenticular shape), subdural hematoma (crescentic shape), subarachnoid hemorrhage, space occupying lesion, hydrocephalus, and cerebral edema
- multiplanar imaging can be performed with newer generation of multidetector CT scanners

Myelography

- introduction of water-soluble, low-osmotic contrast media into subarachnoid space using lumbar puncture followed by x-ray or CT scan
- **indications:** excellent study for disc herniations, traumatic nerve root avulsions, patients with contraindication to MRI

MRI

- **indications:** shows brain and spinal soft tissue anatomy in fine detail, clearly distinguishes white from grey matter (especially T1-weighted series), multiplanar reconstruction helpful in pre-operative assessment

Cerebral Angiography/CT Angiography/MR Angiography

- **indications:** evaluation of vascular lesions such as atherosclerotic disease, aneurysms, vascular malformations, arterial dissection
- conventional digital subtraction angiography remains the gold standard for the assessment of neck and intracranial vessels; however, it is an invasive procedure requiring arterial (femoral) puncture; catheter manipulation has risk of vessel injury (e.g. dissection, occlusion, vasospasm, emboli)
- MRA methods (phase contrast, time of flight, gadolinium-enhanced) and CTA are much less invasive without actual risk to intracranial or neck vessels
- MRA and CTA are often used first as 'screening tests' for the assessment of subarachnoid hemorrhage, vasospasm, aneurysms

Figure 30. Hydrocephalus: ventricular dilatation (may see periventricular low attenuation due to transependymal CSF flow)

Table 16. Two Types of Hydrocephalus

Type	Cause
Communicating/Extra-Ventricular	Obstruction distal to the ventricles (e.g. at the level of the arachnoid granulations); imaging shows all ventricles dilated
Non-Communicating	Obstruction within the ventricular system (e.g. mass obstructing the aqueduct or foramen of Monro); imaging shows dilatation of ventricles proximal to the obstruction

Nuclear Medicine

- SPECT using ^{99m}Tc-exametazime (HMPAO) and ^{99m}Tc-bicisate (ECD) imaging assesses cerebral blood flow by diffusing rapidly across the blood brain barrier and becoming trapped within neurons proportional to cerebral blood flow
- ¹⁸F-DG PET imaging assesses cerebral metabolic activity
- indications: differentiation of residual tumour vs. radiation necrosis; localizing of epileptic seizure foci; evaluation of atypical dementia

Figure 31. Vertebrobasilar circulation (note the incidental basilar tip aneurysm)

Approach to CT Head

- think anatomically, work from superficial to deep
- scan: confirm that the imaging is of the correct patient, whether contrast was used, if the patient is aligned properly, if there is artifact present
- skin/soft tissue: examine the soft tissue superficial to the skull, looking for thickening suggestive of hematoma or edema; also evaluate the ear, orbital contents (globe, fat, muscles), parotid gland, muscles of mastication (masseter, temporalis, pterygoids), visualize pharynx
- bone and airspace (use the bone window): check calvarium, visualize mandible, visualize C-spine (usually C1 and maybe part of C2) for fractures, absent bone, lytic/sclerotic lesions; inspect sinuses and mastoid air cells for opacity that may suggest fluid, pus, blood, tumour, or fracture; status of the orbital floor in cases of facial trauma (coronal series best)

Approach to the CT Head
Some = Scan
Sore = Skin/Soft Tissue
Brains = Bone/Airspace
Demonstrate = Dura/Subdural space
Pushed = Parenchyma
Ventricles = Ventricles/Sulci/Cisterns

Transient ischemic attacks are not associated with radiological findings

- dura and subdural space: crescent-shaped hyperdensity in the subdural space suggests subdural hematoma; lentiform hyperdensity in the epidural space suggests epidural hematoma; check symmetry of dural thickness, where increased thickness may suggest the presence of blood
- parenchyma: asymmetry of the parenchyma suggests midline shift; poor contrast between grey and white matter suggests possible infarction, tumour, edema, infection, or contusion; hyperdensity in the parenchyma suggests enhancing lesions, intracerebral hemorrhage, or calcification; central grey matter nuclei (e.g. globus pallidus, putamen, internal capsule) should be visible, otherwise, suspect infarct, tumour, or infection
- ventricles/sulci/cisterns: examine position of ventricles for evidence of midline compression/shift; hyperdensities in the ventricles suggest ventricular/subdural hemorrhage; enlarged ventricles suggest hydrocephalus; obliteration of sulci may suggest presence of edema causing effacement, possible blood filling in the sulci, or tumour; cistern hyperdensities may suggest blood, pus, or tumour
- please refer to Toronto Notes website for supplementary material on how to approach a head CT

Figure 32. Insular Ribbon Sign (Left side)
Hypodensity of insular cortex representing early sign of infarction

Ddx for Ring Enhancing Cerebral Lesion

- MAGIC DR**
 Metastasis
 Abscess
 Glioblastoma multiforme
 Infarction (subacute/chronic)
 Contusion/hematoma
 Demyelinating disease (e.g. MS)
 Radiation necrosis

Selected Pathology

- see [Neurosurgery, NS20](#) for intracranial mass lesions
- see [Neurosurgery, NS29](#) and [Plastic Surgery, PL29](#) for head trauma
- see [Emergency Medicine, ER7](#) for vertebral trauma
- see [Neurosurgery, NS27](#) and [Orthopedics, OR22](#) for degenerative spinal abnormalities

Cerebrovascular Disease (see [Neurology, N6](#) and [Neurosurgery, NS17](#))

- pathogenesis of stroke: see [Neurology, N48](#)
- best imaging modality: infarcts best detected by MRI > CT

Table 17. Temporal Findings of Infarction with CT and MRI

Time from Stroke Onset	CT	MRI
Hyperacute (0-24 h)	Usually normal within 6 h Edema (loss of grey-white matter differentiation – “insular ribbon sign”, effacement of sulci, mass effect) Hyperattenuating artery “hyperdense MCA sign” representing intravascular thrombus/emboli may be seen in ischemic stroke Hyperattenuating acute blood surrounded by edema may be seen in hemorrhagic stroke	Hyperintensity on DWI within minutes of arterial occlusion due to restriction of water movement indicative of cytotoxic edema Hypointensity on ADC within minutes Hyperintensity upon T2/FLAIR approximately 6 h after onset due to edema (loss of grey-white matter differentiation, effacement of sulci, mass effect)
Acute (24 h-1 wk)	Increasing edema (seen as hypoattenuation) may result in significant positive mass effect	Continued hyperintensity on DWI Hypointensity on ADC reaches nadir at 3-5 d and begins to increase Continued hyperintensity on T2/FLAIR
Subacute (1-3 wk)	Resolution of edema leads to increased attenuation of infarcted area that may regain near-normal density and mask stroke “fogging phenomenon”	Continued hyperintensity on DWI due to “T2 shine through” Intensity on ADC continues to rise, pseudonormalizes at 10-15 d, and then surpasses that of surrounding normal tissue Continued hyperintensity on T2/FLAIR
Chronic (>3 wk)	Encephalomalacia (parenchymal volume loss) appears as hypoattenuation with negative mass effect	Hyperintensity on DWI/T2/FLAIR progressively decreases ADC intensity remains elevated

- carotid artery disease
 - best imaging modality: Duplex Doppler U/S
 - other modalities: MRA or CTA if carotid angioplasty or endarterectomy is under consideration (conventional angiography reserved for inadequate MRA or CTA)

Multiple Sclerosis (see [Neurology, N52](#))

- best imaging modality: MRI has high sensitivity in diagnosing MS (>90%) but low specificity (71-74%)
- findings
 - characteristic lesion on MRI is cerebral or spinal plaque
 - plaques typically found in periventricular region, corpus callosum (arranged at right angles to the corpus callosum), centrum semiovale, and to a lesser extent in deep white matter structures and basal ganglia
 - “Dawson’s fingers” refers to perivenular regions of demyelination that are seen to radiate outwards into the deep periventricular region
 - plaques usually have ovoid appearance, hyperintense on T2 and hypointense on T1
 - conventional T2 may underestimate plaque size and overall plaque burden – advanced techniques (diffusion tensor imaging and MR spectroscopy) can be of use

Figure 33. CT images of early infarct:
(A) absence of left insular ribbon (B) hyperdense artery

Figure 34. DWI of patient with right frontotemporal infarct

- perivascular and interstitial edema may be prominent
- spinal cord lesions typical of MS
 - ♦ little or no cord swelling
 - ♦ unequivocal hyperintensity on T2-weighted sequences
 - ♦ size at least 3 mm but less than 2 vertebral segments in length
 - ♦ occupy only part of the cord in cross-section
 - ♦ focal (i.e. clearly delineated and circumscribed on T2-weighted sequences)

CNS Infections

• leptomeningitis

- pathogenesis: inflammation of the pia or arachnoid mater, most often secondary to hematogenous spread from infection or via organisms gaining access across areas not protected by the blood-brain barrier (choroid plexus or circumventricular organs)
 - ♦ pathogens include: *S. pneumoniae*, *H. influenzae*, *N. meningitidis*, *L. monocytogenes*
- best imaging modality: MRI (T2-weighted/FLAIR) superior to CT
- findings
 - ♦ meningeal enhancement (following the gyri/sulci and/or basal cisterns), hydrocephalus (communicating), cerebral swelling, subdural effusion
 - ♦ a normal MRI does not rule out leptomeningitis

• herpes simplex encephalitis (see [Infectious Diseases, ID19](#))

- pathogenesis: inflammation of the brain parenchyma secondary to infection with herpes simplex virus, asymmetrically affects the limbic regions of the brain (i.e. temporal lobes, orbitofrontal region, insula, and cingulate gyrus)
- best imaging modality: MRI (T1- and T2-weighted)
- findings
 - ♦ acute (within 4-5 d): asymmetric high intensity lesions on T2 MRI in temporal and inferior frontal lobes strongly suggestive
 - ♦ DDx: infarct, tumour, status epilepticus, limbic encephalitis
 - ♦ CT may show low density in temporal lobe and insula; rarely basal ganglia involvement
 - ♦ long-term may show parenchymal loss to affected areas

• cerebritis/cerebral abscess

- pathogenesis: an infection of the brain parenchyma (cerebritis) which can progress to a collection of pus (abscess), most frequently due to hematogenous spread of infectious organisms, commonly located in the distribution of the MCA
- pathogens include: *S. aureus* (often in IV drug users, nosocomial), *Streptococcus*, Gram negative bacteria, *Bacteroides*
- best imaging modality: MRI including DWI imaging series (abscess will be DWI positive); CT still used as a viable alternative
- findings according to one of four stages of abscess formation
 - ♦ early cerebritis (1-3 d): inflammatory infiltrate with necrotic centre, low intensity on T1, high intensity on T2
 - ♦ late cerebritis (4-9 d): ring enhancement may be present
 - ♦ early capsule (10-13 d): ring enhancement
 - ♦ late capsule (14 d or greater): well demarcated ring-enhancing lesion, low intensity core, with mass effect; considerable edema around the lesion, seen as hyperintensity on T2

Figure 35. T2-weighted FLAIR: (A) sagittal (B) axial images of multiple sclerosis with periventricular "Dawson's Fingers"

Figure 36. T2-weighted (FLAIR) coronal image of herpes simplex virus encephalitis affecting temporal lobes

Musculoskeletal System

Modalities

- see [Imaging Modalities, MI2](#) for advantages and disadvantages of the following

Plain Film/X-Ray

- usually initial study used in evaluation of bone and joint disorders
- indications: fractures and dislocations, arthritis, assessment of malalignment, orthopedic hardware, and bone tumours (initial)
- minimum of two films orthogonal to each other (usually AP and lateral) to rule out a fracture
- image proximal and distal joints, particularly important with paired bones (e.g. radius/ulna)
- minimally effective in evaluating soft tissue injury

CT

- evaluation of fine bony detail
- indications: assessment of complex, comminuted, intra-articular, or occult fractures including distal radius, scaphoid, skull, spine, acetabulum, calcaneus, and sacrum
- evaluation of soft tissue calcification/ossification

MRI

- indications: evaluation of internal derangement of joints (e.g. ligaments, joint capsule, menisci, labrum, cartilage), assessment of tendons and muscle injuries, characterization and staging of soft tissue and bony masses

Ultrasound

- indications: tendon injury (e.g. rotator cuff, Achilles tendon), detection of soft tissue masses and to determine whether cystic or solid, detection of foreign bodies, U/S-guided biopsy and injections
- Doppler determines vascularity of structures

Nuclear Medicine (Bone Scintigraphy)

- determine the location and extent of bony lesions
- ^{99m}Tc -methylene diphosphonate localizes to areas of increased bone turnover or calcification – growth plate in children, tumours, infections, fractures, metabolic bone disease (e.g. Paget's), sites of reactive bone formation, and periostitis
- advantages: very sensitive, capable of imaging entire body with relatively low dose radiation
- disadvantages: low specificity, not widely available due to special requirements (e.g. gamma camera, radiopharmaceuticals)

Approach to Bone X-Rays

- identification: name, MRN, age of patient, type of study, region of investigation
- soft tissues: swelling, calcification/ossification
- joints: alignment, joint space, presence of effusion, osteophytes, erosions, bone density, overall pattern, and symmetry of affected joint
- bone: periosteum, cortex, medulla, trabeculae, density, articular surfaces, bone destruction, bone production, appearance of the edges or borders of any lesions

Trauma

Fracture/Dislocation

- description of fractures
- site of fracture (bone, region of bone, intra-articular vs. extra-articular)
- pattern of fracture line (simple vs. comminuted)
- displacement (distal fragment with reference to the proximal fragment)
- soft tissue involvement (calcification, gas, foreign bodies)
- type of fracture (stress vs. pathologic)
- for specific fracture descriptions and characteristics of fractures, see Orthopedics, OR4

Arthritis

Radiographic Hallmarks of Osteoarthritis

- joint space narrowing – typically non-uniform
- subchondral sclerosis
- subchondral cyst formation
- osteophytes

Radiographic Hallmarks of Rheumatoid Arthritis

- joint space narrowing – typically uniform
- soft tissue swelling
- erosions
- periarticular osteopenia

Bone Tumour

Approach

- metastatic tumours to bone are much more common than primary bone tumours, particularly if age >40 yr
 - diagnosis usually requires a biopsy if primary not located
 - few benign tumours/lesions have potential for malignant transformation
 - MRI is good for tissue delineation and pre-operative assessment of surrounding soft tissues, neurovascular structures, and medullary/marrow involvement
 - plain film is less sensitive than other modalities but useful for assessing aggressiveness and constructing differential diagnosis

Considerations and Tumour Characteristics

- for specific bone tumours, see [Orthopedics, OR45](#)
- age: most common tumours by age group
 - <1 yr of age: metastatic neuroblastoma
 - 1-20 yr of age: Ewing's sarcoma in tubular bones
 - 10-30 yr of age: osteosarcoma and Ewing's tumour in flat bones
 - >40 yr of age: metastases, multiple myeloma, and chondrosarcoma
- multiplicity: metastases, myeloma, lymphoma, fibrous dysplasia, enchondromatosis
- location within bone
 - epiphysis: giant cell tumour, chondroblastoma, geode, eosinophilic granuloma, infection
 - metaphysis: simple bone cyst, aneurysmal bone cyst, enchondroma, chondromyxoid fibroma, nonossifying fibroma, osteosarcoma, chondrosarcoma
 - diaphysis: fibrous dysplasia, aneurysmal bone cyst, brown tumours, eosinophilic granuloma, Ewing's sarcoma

Figure 37. X-ray of first carpometacarpal joint: normal image (left) and osteoarthritis (right) with joint space narrowing and subchondral sclerosis

Figure 38. Rheumatoid arthritis (A) compared with osteoarthritis (B) changes on X-ray

- expansile
 - aneurysmal bone cyst, giant cell tumour, enchondromas, brown tumours, metastases (especially renal and thyroid), plasmacytoma
- matrix mineralization
 - chondroid (popcorn calcification) or osseous
- margin/zone of transition: area between lesion and normal bone
- cortex: intact, disturbed
- periosteal reaction: onion-skinning, sunburst, Codman's triangle, periosteal neocortex
- soft tissue mass

- Benign Lesions which may have Aggressive Features**
- Osteomyelitis
 - Osteoblastoma
 - Aneurysmal bone cyst
 - Langerhans cell histiocytosis
 - Myositis ossificans

Figure 39. Radiographic appearance of bone remodelling and destruction processes

- Periosteal Reaction**
- "Onion skinning" = Ewing's sarcoma
 - "Sunburst", "hair on end" = osteosarcoma
 - "Codman's triangle" = osteosarcoma, Ewing's sarcoma, subperiosteal abscess

Table 18. Characteristics of Benign and Malignant Bone Lesions

Benign	Malignant
Thin sclerotic margin/sharp delineation of lesion	Poor delineation of lesion – wide zone of transition
Overlying cortex intact	Loss of overlying cortex/bony destruction
No or simple periosteal reaction	Periosteal reaction
No soft tissue mass	Soft tissue mass

Metastatic Bone Tumours

- all malignancies have potential to metastasize to bone
- metastases are 20-30x more common than primary bone tumours
- metastasis can cause a lytic or a sclerotic reaction when seeding to bone
- when a primary malignancy is first detected, a bone scan is often part of the initial workup
- may present with pathological fractures or pain
- biopsy or determination of primary is the only way to confirm the diagnosis
- most common metastatic bone tumours: breast, prostate, lung, see Orthopedics, OR45

- Lytic = decreased density
- Sclerotic = increased density

Table 19. Characteristic Bone Metastases of Common Cancers

Lytic	Sclerotic	Expansile	Peripheral
Breast	Prostate	Thyroid	Kidney
Lung	Breast	Renal	Lung
Thyroid	Lymphoma		Melanoma
Kidney	Lung		(KLM: flies to the periphery)
Multiple myeloma	Bowel		
	Medulloblastoma		
	Treated tumours		

Infection

Osteomyelitis

- MRI is the imaging modality of choice for demonstrating bone, bone marrow, and soft tissue abnormalities
- ^{99m}Tc, followed by ¹¹¹In-labeled white cell scan or gallium radioisotope scan
- plain film changes visible 8-10 d after process has begun
 - soft tissue swelling
 - local periosteal reaction
 - pockets of air (from anaerobes) may be seen in the tissues, may also suggest necrotizing fasciitis
 - mottled and nonhomogeneous with a classic "moth-eaten" appearance
 - cortical destruction

Bone Abscess

- overlying cortex has periosteal new bone formation
- sharply outlined radiolucent area with variable thickness in zone of transition
- variable thickness periosteal sclerosis
- sequestrum: a piece of dead bone within a Brodie's abscess
- a sinus tract or cloaca may communicate between the abscess through the cortex to the surface of the bone
- best modality: MRI for bone, bone marrow, and soft tissue abnormalities; CT for sequestra and cortical erosions

Metabolic Bone Disease

Osteoporosis

- reduction in amount of normal bone mass; fewer and thinner trabeculae; diffuse process affecting all bones
- DEXA: gold standard for measuring bone mineral density
 - T-score: the number of standard deviations from the young adult mean, most clinically valuable
 - ◆ osteopenia: $-2.5 < \text{T-score} < -1$
 - ◆ osteoporosis: $\text{T-score} \leq -2.5$
 - Z-score: the number of standard deviations from the age-matched mean
 - risk of fracture: related to bone mineral density, age, history of previous fractures, steroid therapy
 - diagnostic sensitivity of DEXA highest when bone mineral density measured at lumbar spine and proximal femur
- appearance on plain film
 - osteopenia: reduced bone density on plain films
 - ◆ may also be seen with osteomalacia, hyperparathyroidism, and disuse
 - compression of vertebral bodies
 - biconcave vertebral bodies ("codfish" vertebrae)
 - long bones have appearance of thinned cortex and increased medullary cavity
 - ◆ look for complications of osteoporosis (e.g. insufficiency fractures: hip, vertebrae, sacrum, pubic rami)
- see [Endocrinology, E40](#)

Osteoporosis
Reduced amount of bone

Osteomalacia
Normal amount of bone, but reduced mineralization of normal osteoid

Osteomalacia/Rickets

- reduction in bone mineral density; normal amount of bone, but reduced mineralization of normal osteoid
- usually due to vitamin D deficiency, resulting in softening and bowing of long bones
- similar to osteoporosis, initial radiological appearance of osteopenia (coarse and poorly defined bone texture)
- "fuzzy"; ill-defined trabeculae
- Looser's zones (pseudofracture)
 - characteristic radiologic feature
 - fissures or clefts at right angles to long bones and extending through cortex
 - DDx: chronic renal disease, fibrous dysplasia, hyperthyroidism, Paget's, osteodystrophy, X-linked hypophosphatemia

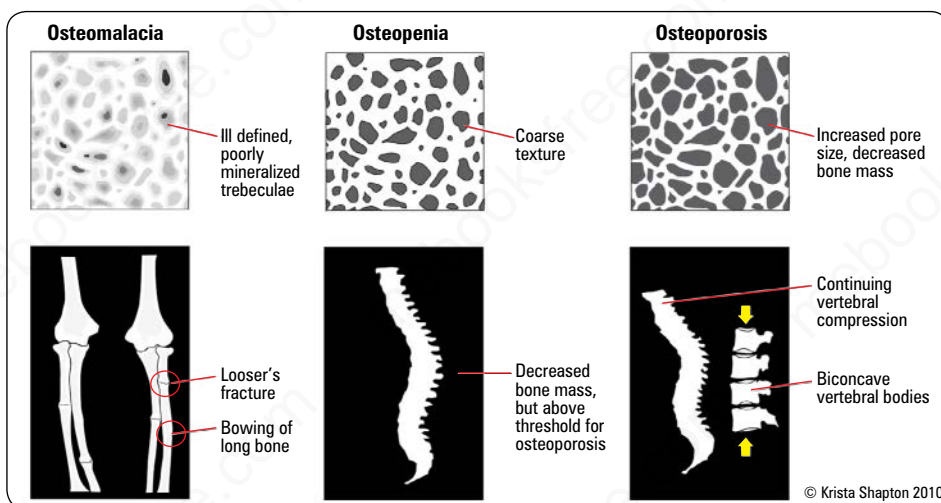

Figure 40. Osteomalacia, osteopenia, and osteoporosis

Hyperparathyroidism

- most common cause is renal failure (secondary hyperparathyroidism)
- chondrocalcinosis
- calcium crystal deposition in hyaline cartilage or fibrocartilage (including arteries and peri-articular soft tissue)
- resorption of bone typically in hands (subperiosteal and at tufts), sacroiliac joints (subchondral), skull (“salt and pepper” appearance), osteoclastoma (brown tumours)
- “rugger jersey spine”: band-like osteosclerosis at superior/inferior margins of vertebral bodies

Paget’s Disease

- abnormal remodelling involving single or multiple bones – especially skull, spine, pelvis
- 3 phases: 1st phase = lytic, 2nd phase = mixed (lytic/sclerotic), 3rd phase = sclerotic
- features
- coarsening of the trabeculae with bone expansion
- bone softening/bowing
- bone scan will reveal high activity, especially at bone ends
- thickened cortex
- see [Endocrinology, E44](#)

Nuclear Medicine

Brain

- ^{99m}Tc -exametazime (HMPAO) and ^{99m}Tc -bicisate (ECD) imaging used in SPECT to assess cerebral blood flow and cellular metabolism, taken up predominantly in grey matter
 - used for dementia, traumatic brain injury, and to a lesser extent vasculitis, neuropsychiatric disorders, and occasionally stroke
 - most commonly used tracers to confirm brain death (i.e. absent blood flow to the brain and absent uptake on delayed planar and SPECT images in brain and brainstem, assuming study is technically adequate)
 - either tracer can be used for seizure imaging to assess for the most likely location of epileptogenic focus but usually must be made available for 24 h and the patient followed by a nurse who is competent to administer the activity at the time of seizure
- PET imaging assesses metabolic activity most commonly with ^{18}F FDG; used for dementia imaging, grade and stage of brain tumours, occasionally for seizure disorder imaging, and vasculitis; PET imaging with amyloid tracers for diagnosis of Alzheimer’s disease is becoming more common
- CSF imaging, intrathecal administration of ^{111}In DTPA to evaluate CSF leak or to differentiate normal pressure hydrocephalus from brain atrophy
- CSF shunt evaluation for obstruction (most commonly ventriculoperitoneal) with sterile or pyrogen free ^{99m}Tc (usually) or ^{111}In -DTPA; small quantity of activity is injected into the reservoir under sterile conditions and should flow freely into the peritoneal cavity by 45 min; maneuvers such as pumping the shunt, sitting the patient upright or ambulating are acceptable to encourage flow during this time
- adrenergic imaging of the heart with MIBG has been used to differentiate dementias with autonomic dysfunction (i.e. Lewy Body and Parkinson’s disease) from other forms of dementia (i.e. autonomic impairment associated with decreased MIBG activity in the heart)

Thyroid

Radioactive Iodine Uptake (see [Endocrinology, E21](#))

- index of thyroid function (trapping and organification of iodine)
- radioactive ^{131}I given PO to fasting patient (small quantity)
- measure percentage of administered iodine taken up by thyroid
- increased RAIU: toxic multinodular goitre, toxic adenoma, Graves’ disease
- decreased RAIU: subacute thyroiditis, late Hashimoto’s disease, exogenous thyroid hormone or iodine, falsely decreased in patient with recent radiographic contrast studies, high dietary iodine (e.g. seaweed, taking a “thyroid vitamin”)
- **important** – iodine uptake helps in the differential of hyperthyroidism only, not hypothyroidism (exception is pediatrics)

Thyroid Imaging (Scintiscan)

- ^{99m}Tc -pertechnetate IV or radioactive iodine (^{123}I); most Canadian sites use pertechnetate to reduce cost
- provides functional anatomic detail
- hot (hyperfunctioning) lesions: usually benign (e.g. adenoma, toxic multinodular goitre), cancer very unlikely (less than 1%)
- cold (hypofunctioning) lesions: cancer must be considered until biopsy negative even though only 6-10% are cancerous; decision to biopsy should be based on clinical and sonographic features
- isointense i.e. “warm” lesions: cancer must be considered as an isointense lesion may represent cold nodules superimposed on normal tissue; if cyst suspected, correlate with U/S

Figure 41. Multinodular goitre (top). Cold nodule (bottom)

Radioiodine Ablation

- ^{131}I for Graves' disease, multinodular goitre, thyroid cancer (in the case of thyroid cancer, ablation performed at higher dose and after thyroidectomy)
- serum thyroglobulin used to detect recurrent thyroid cancer in a patient that has received ablation
- advice should be given for patient-specific precautions to remain away from family members and caregivers to reduce radiation exposure after thyroid ablation, do not initiate pregnancy for 6 mo, small risk of exophthalmos, thyroid storm, secondary malignancy

Pediatric Hypothyroidism

- pertechnetate thyroid scan can differentiate thyroid agenesis, hemiagenesis, lingular thyroid, organification defect, however should not wait for a diagnosis to start thyroid hormone replacement in a neonate; start immediately

Respiratory

V/Q Scan

examine areas of lung in which ventilation and perfusion do not match

- ventilation scan
 - patient breathes radioactive gas (nebulized $^{99\text{m}}\text{Tc}$ -DTPA, ^{133}Xe , or most commonly Technegas) through a closed system, filling alveoli proportionally to ventilation
 - ventilation scan defects indicate: airway obstruction (i.e. air trapping), chronic lung disease, bronchospasm, tumour mass obstruction
- perfusion scan
 - radiotracer injected IV ($^{99\text{m}}\text{Tc}$ -MAA) → trapped in pulmonary capillaries (0.1% of arterioles occluded) according to blood flow
 - relatively contraindicated in severe pulmonary HTN, right-to-left shunt, previous history of pneumonectomy, small child. In these cases fewer particles are usually given
- to rule out PE
 - indications: some institutions favour in pregnancy (lower radiation dose to breast than CT), or where CT contrast contraindicated (e.g. contrast allergy, renal failure)
 - areas of lung that are well-ventilated but not perfused (unmatched defect) are suspicious for acute infarction
 - defects are wedge-shaped, extend to periphery, usually bilateral and multiple
 - often reported as high probability (> 2 large i.e. segmental mismatched perfusion defects), intermediate, low, very low, or normal according to modified PLOPED II criteria although now are increasingly reported as PE present, indeterminate or normal
 - useful in finding clinically important emboli
 - decreased detection of incidentalomas commonly found on CT
- not valid for assessment of PE when patients have consolidation and the test can be limited by ventilatory problems (e.g. COPD), much like CT
- modified V/Q scan (perfusion only, lower dose contrast) may be used for pregnant patients if CXR is normal or if there are ventilatory problems

Ventilation Scan Defects Indicate...

ABC TumoUr
Airway obstruction
Bronchospasm
Chronic lung disease
Tumour mass obstruction

Perfusion Scan Defects Indicate...

Reduced blood flow due to PE
COPD
Asthma
Bronchogenic carcinoma
Inflammatory lung diseases (pneumonia, sarcoidosis)
Mediastinitis
Mucous plug
Vasculitis

V/Q Scan

For PE investigation: normal scan makes PE unlikely
Probability of PE: high 80-100%, intermediate 20-80%, low <20%, very low <10%

Cardiac

Myocardial Perfusion Scanning

- to investigate coronary artery disease (CAD), assess treatment of CAD, pre-op risk stratification, viability testing
- $^{99\text{m}}\text{Tc}$ -sestamibi, or $^{99\text{m}}\text{Tc}$ -tetrofosmin are used most commonly, thallium 201 was used previously but largely discontinued due to high radiation doses to patients and unfavourable imaging characteristics; today thallium still used for viability studies
- injected at peak exercise (85% max predicted heart rate by the Bruce protocol, chest pain, ECG changes) or after persantine challenge (vasodilator), or after dobutamine infusion (chronotropic, again to 85% predicted heart rate); can be done as stress only protocol with optional rest or as stress and rest combined protocol (i.e. as 1 day or 2 day protocol)
- patients with left bundle usually given pharmacologic stress because ECG is difficult to interpret for ST changes and avoids a characteristic artifact
- pharmacologic stress contraindicated if sBP is <90; persantine exacerbates asthma, so patients with asthma and wheeze who cannot exercise usually get dobutamine infusion; reverse persantine with aminophylline or caffeine
- persistent defect (at rest and stress) suggests infarction or myocardial scar; reversible defect (only during stress) suggests ischemia
- used to discriminate between reversible (ischemia) vs. irreversible (infarction) changes when other investigations are equivocal
- Courage trial indicates that patients with >10% ischemic myocardium benefit most from revascularization
- see [Cardiology and Cardiac Surgery, C13](#)

Radionuclide Ventriculography

- ^{99m}Tc -tagged to red blood cells, tagged albumin is also acceptable
- first pass through RV \rightarrow pulmonary circulation \rightarrow LV; provides information about RV function, presence of shunts
- cardiac MUGA scan sums multiple cardiac cycles, usually at least 200 beats
- evaluation of LV function and regional wall motion, ejection fraction
- images are obtained by gating (synchronizing) the count acquisitions to the ECG signal
- can assess diastolic dysfunction
- provides information on ejection fraction (normal = 50-65%), ventricular volume, and wall motion
- indications: most commonly to monitor potential cardiac toxicity with chemotherapy or herceptin, as a gold standard of ejection fraction in defibrillator workup

Abdomen and Genitourinary System

HIDA Scan (Cholescintigraphy)

- IV injection of ^{99m}Tc -disofenin (DISIDA) or ^{99m}Tc -mebrofenin which is bound to protein, taken up, and excreted by hepatocytes into biliary system
- can be performed in non-fasting state but prefer NPO after midnight
- indicated in workup of cholecystitis when abdominal ultrasound result is equivocal:
 - acute cholecystitis: no visualization of gallbladder at 4 h or 1 h after administration of morphine
 - chronic cholecystitis: no visualization of gallbladder at 1 h but seen at 4 h or after morphine administration
- gallbladder visualized when cystic duct is patent (rules out acute cholecystitis with >99% certainty), usually seen by 30 min-1 h
- differential diagnosis of obstructed cystic duct: acute/chronic cholecystitis, decreased hepatobiliary function (commonly due to alcoholism), bile duct obstruction, parenteral nutrition, fasting less than 4 h or more than 24 h
- also used to assess bile leaks post-operatively or in trauma
- gallbladder ejection fraction (>38% is normal) can be measured after a fatty meal or CCK to assess for biliary dyskinesia

RBC Scan

- IV injection of radiotracer with sequential images of the abdomen (^{99m}Tc RBCs)
- GI bleed
 - if bleeding acutely at <0.5 mL/min, the focus of activity in the images generally indicates the site of the acute bleed, look for a change in shape and location on sequential image, requires active bleeding to localize
 - if bleeding acutely at >0.5 mL/min, use angiography (more specific)
- liver lesion evaluation
 - hemangioma has characteristic appearance: cold early (limited blood flow to lesion), fills in later (accumulation of tagged cells greater than surrounding liver parenchyma)

Other Important Nuclear Medicine Abdominal Tests

- Meckel's Scan: uses ^{99m}Tc pertechnetate; give patient ranitidine premedication; Meckel's diverticulum contains gastric mucosa which will light up at the same time as the stomach and get brighter with time like stomach
- ^{111}In octreoscan: a somatostatin analog used for evaluation and staging of neuroendocrine tumours including carcinoid; gastrinoma and carcinoid tend to be more octreotide avid than insulinoma.
- iodinated MIBG: a norepinephrine analogue, used for pheochromocytoma, neuroblastoma and medullary thyroid cancer most commonly; limited cardiac applications as above
- solid and liquid gastric emptying: a standardized solid or liquid meal is labelled, usually with ^{99m}Tc sulfur colloid and gastric emptying studied over time. There are normal ranges for solids and liquids

Urea Breath Test

- indication: diagnosis of gastric *Helicobacter pylori* infection
- patient administered ^{14}C -labelled urea orally, urea metabolized by *H. pylori* to ammonia and $^{14}\text{CO}_2$, ^{14}C -labelled CO_2 is measured via plastic filament detectors or liquid scintillation

Functional Renal Imaging

- evaluation of renal function and anatomy using ^{99m}Tc DTPA or ^{99m}Tc MAG3
- frequently used to provide index of relative function between two kidneys
- frequently used in adults to assess for UPJ obstruction (by assessing the clearance half time with lasix), and assess renal transplants or as a nuclear GFR study in patients wanting to donate kidneys
- in children, imaging with ^{99m}Tc DMSA is used to assess for pyelonephritis
- in children, the injection of tracer into the bladder via foley catheter is often used to assess for reflux

Bone

Bone Scan

- isotopes, usually ^{99m}Tc -diphosphonate
- radioactive tracer binds to hydroxyapatite of bone matrix
- increased binding when increased blood supply to bone and/or high bone turnover (active osteoblasts)
- indications: bone pain of unknown origin, staging or restaging of cancer with bony mets (or primary bone cancer), imaging of arthroplasty complications like loosening or infection, osteomyelitis imaging
- when used to assess for osteomyelitis, usually done in combination with gallium or white blood cell scan
- differential diagnosis of positive bone scan: bone metastases (breast, prostate, lung, thyroid), primary bone tumour, arthritis, fracture, infection, anemia, Paget's disease
- lytic lesions like multiple myeloma, renal cell cancer, eosinophilic granuloma: typically normal or cold (false negative); need a skeletal survey
- "superscan": increased bone uptake and poor renal uptake due to diffuse metastases (breast, prostate) or metabolic causes (e.g. renal osteodystrophy)

Interventional Radiology

Vascular Procedures

Angiography

- injection of contrast material through a catheter placed directly into an artery or vein to delineate vascular anatomy
- catheter can be placed into a large vessel (e.g. aorta, vena cava) for a "flush" or selectively placed into a branch vessel for more detailed examination of smaller vessels and specific organs
- indications: diagnosis of primary occlusive or stenotic vascular disease, aneurysms, coronary, carotid and cerebral vascular disease, PE, trauma, bleeding (GI, hemoptysis, hematuria), vascular malformations, as part of endovascular procedures (endovascular aneurysm repair, thrombolysis, stenting, and angioplasties)
- complications (<5% of patients): puncture site hematoma, infection, pseudoaneurysm, AV fistula, dissection, thrombosis, embolic occlusion of a distal vessel
- due to improved technology, non-invasive evaluation of vascular structures is being performed more frequently (colour Doppler U/S, CTA, and MRA)
- see *Neuroradiology, MI18*

Percutaneous Transluminal Angioplasty and Stents

- introduction and inflation of a balloon into a stenosed or occluded vessel to restore distal blood supply
- common alternative to surgical bypass grafting with 5 yr patency rates similar to surgery, depending on site
- renal, iliac, femoral, mesenteric, subclavian, coronary, and carotid artery stenoses are amenable to treatment
- vascular stents may help improve long-term results by keeping the vessel wall patent after angioplasty ; also used for angioplasty failure or complications
- stent grafts (metal mesh covered with durable fabric) may provide an alternative treatment option for aneurysms and AV fistulas
- complications: similar to angiography, but also includes vessel rupture

Thrombolytic Therapy

- may be systemic (IV) or catheter directed
- infusion of a fibrinolytic agent (urokinase, streptokinase, TNK, tPA – used most commonly) via a catheter inserted directly into a thrombus
- can restore blood flow in a vessel obstructed with a thrombus or embolus
- indications: treatment of ischemic limb (most common indication), early treatment of MI or stroke to reduce organ damage, treatment of venous thrombosis (DVT or PE)
- complications: bleeding, stroke, distal embolus, reperfusion injury with myoglobinuria and renal failure if advanced ischemia present

Embolization

- injection of occluding material into vessels
- permanent agents: amplatzer plugs, coils, glue, and onyx
- temporary: gel foam, autologous blood clots
- indications: management of hemorrhage (epistaxis, trauma, GI bleed, GU bleed), treatment of arteriovenous malformation, pre-operative treatment of vascular tumours (bone metastases, renal cell carcinoma), varicocele embolization for infertility, symptomatic uterine fibroids
- complications: post-embolization syndrome (pain, fever, leukocytosis), unintentional embolization of a non-target organ with resultant ischemia

Advanced ischemia patients should receive surgery rather than thrombolysis

Chemoembolization delivers chemotherapy directly into the tumour through its feeding blood supply and traps the drug in place by embolization

Thrombolytic Therapy for Pulmonary Embolism

Cochrane Database Syst Rev 2015;(9):CD004437

Purpose: To assess the effects of thrombolytic therapy in patients with acute pulmonary embolism (PE).

Methods: Systematic review of RCTs evaluating thrombolytic therapy followed by heparin versus heparin alone, heparin plus placebo or surgical intervention in patients with acute PE. Studies comparing two different thrombolytic agents or different doses of the same thrombolytic drug were not considered eligible. Main outcomes of interest were death, recurrence of PE, and major and minor hemorrhagic events.

Results: Eighteen trials with 2,197 participants were included. Thrombolytics plus heparin were associated with a reduction in odds of death relative to heparin alone or heparin plus (OR 0.57, 95% CI 0.37 to 0.87, $P = 0.02$) and recurrence of PE (OR 0.51; 0.29 to 0.89, $P = 0.02$). Incidence of major and minor hemorrhagic events was statistically significantly higher in the thrombolytics group than the control group (OR 2.90, 95% CI 1.95 to 4.31, $P < 0.001$). Length of hospital stay (mean difference (MD) -1.35, -4.27 to 1.58) and quality of life were similar between groups. Based on one study, stroke occurred more often in the thrombolytics group (OR 12.10, 1.57 to 93.39).

Conclusion: Low-quality evidence suggests thrombolytics reduce death following acute PE compared with heparin and may be helpful in reducing PE recurrence, but may cause more major and minor hemorrhagic events and stroke events.

Inferior Vena Cava Filter

- insertion of temporary or permanent metallic “umbrellas” to mechanically trap emboli and prevent PE
- inserted via femoral vein, jugular vein, or antecubital vein
- usually placed infrarenally to avoid renal vein thrombosis
- indications: contraindication to anticoagulation, failure of adequate anticoagulation (e.g. recurrent PE despite therapeutic anticoagulant levels), complication of anticoagulation

Central Venous Access

- variety of devices available
- PICC, external tunneled catheter (Hickman or dialysis catheters), subcutaneous port (Portacath®)
- indications: chemotherapy, TPN, long-term antibiotics, administration of fluids and blood products, blood sampling
- complications: venous thrombosis, central venous stenosis, infection including sepsis, and pneumothorax

Figure 42. Retrievable IVC filter

Indications for Central Venous Access

FAT CAB

Fluids

Antibiotics

TPN

Chemotherapy

Administration of blood

Blood sampling

Nonvascular Interventions

Percutaneous Biopsy

- replaces open surgical procedure
- many sites are amenable to biopsy using U/S, fluoroscopy, CT or MR guidance
- complications: false negative (sampling error or tissue necrosis), pneumothorax in 30% of lung biopsies (chest tube required in ~5%), acute pancreatitis (pancreatic biopsies), bleeding from liver biopsies in patients with uncorrectable coagulopathies or ascites (can be minimized with transjugular approach)

Abscess Drainage

- placement of a drainage catheter into an infected fluid collection
- administer broad spectrum IV antibiotics prior to procedure
- routes: percutaneous (most common), transgluteal, transvaginal, transrectal
- complications: hemorrhage, injury to intervening structures (e.g. bowel), bacteremia, sepsis

Percutaneous Biliary Drainage/Cholecystostomy

- placement of drainage catheter ± metallic stent into obstructed biliary system (PBD) or gallbladder (cholecystostomy) for relief of jaundice or infection
- percutaneous gallbladder access can be used to crush or remove stones
- indications
 - cholecystostomy: acute cholecystitis
 - PBD: biliary obstruction secondary to stone or tumour, cholangitis
- complications
 - acute: sepsis, hemorrhage
 - long-term: tumour ingrowth and stent occlusion

Percutaneous Nephrostomy

- placement of catheter into renal collecting system
- indications: hydronephrosis, pyonephrosis, ureteric injury with or without urinary peritonitis (traumatic or iatrogenic)
- complications: bacteria and septic shock, hematuria due to pseudoaneurysm or AV fistulas, injury to adjacent organs

Gastrostomy/Gastrojejunostomy

- percutaneous placement of catheter directly into either stomach (gastrostomy) or through stomach into small bowel (transgastric jejunostomy)
- indications: inability to eat (most commonly CNS lesion, e.g. stroke), esophageal obstruction, or decompression in gastric outlet obstruction
- complications: gastroesophageal reflux with aspiration, peritonitis, hemorrhage, bowel or solid organ injury

Radiofrequency Ablation

- U/S- or CT-guided probe is inserted into tumour, radiofrequency energy delivered through probe causes heat deposition and tissue destruction
- indications: hepatic tumours (HCC and metastases), renal tumours
- complications: destruction of neighbouring tissues and structures, bleeding

Figure 43. Femoral arteriogram: distal occlusion of superficial femoral artery

Breast Imaging

Modalities

Mammography

Description

- x-ray imaging of the breasts for screening in asymptomatic patients, or diagnosis of clinically-detected or screening-detected abnormalities (see [General Surgery, GS56](#))
- routine evaluation involves two standard views: cranio-caudal and medial-lateral-oblique

Indications

- screening
 - begin screening from age 50 q2-3yr
 - no strong data to support screening >70 yr, but may continue screening if in good general health
 - if <50, screening is only recommended for those with high risk of breast cancer
 - screening detects 2-8 cancers/1,000 women screened
- surveillance
 - follow-up of women with previous breast cancer
- diagnostic: includes mammography with special views and/or ultrasound
 - workup of an abnormality that may be suggestive of breast cancer including a lump or thickening, localized nodularity, dimpling or contour deformity, a persistent focal area of pain, and spontaneous serous or sanguinous nipple discharge from a single duct
 - women with abnormal screening mammograms
 - suspected complications of breast implants

Table 20. Breast Imaging Reporting and Data System (BI-RADS®) Mammography Categories

Assessment Categories	Imaging Findings	Follow-Up Recommendations
BI-RADS 0	Incomplete	Additional imaging Comparison to prior films
BI-RADS 1	Negative	Routine screening
BI-RADS 2	Benign	Routine screening
BI-RADS 3	Probably benign Likelihood of malignancy is <2%	Unilateral mammogram at 6 mo
BI-RADS 4	Suspicious abnormality	Biopsy
BI-RADS 5	Highly suspicious of malignancy Likelihood of malignancy is 95%	Biopsy
BI-RADS 6	Malignancy confirmed by biopsy	Definitive therapy

Breast Ultrasound

Indications

- characterization of palpable abnormalities
 - ultrasound is 1st line <30 yr and in lactating and pregnant women
 - >30 yr need mammogram first
- further characterization of mammographic findings
- guidance for interventional procedures

Breast MRI

Description

- contrast-enhanced MRI of the breasts
- sensitive for detecting invasive breast cancer (95-100%) but specificity variable (37-97%)
- for diagnosis, used only after mammography and U/S investigation
- use as a screening modality is limited to high-risk patients, in conjunction with mammography

Indications

- “problem-solving” of indeterminate findings following complete mammographic and ultrasound workup
- evaluation of patients with suspected silicone implant rupture and problems associated with breast implants
- evaluation of previously diagnosed breast cancer: positive margins, recurrence, response to chemotherapy

- high-risk screening
 - known BRCA1 or BRCA2 mutation, or other gene predisposing to breast cancer, or untested first-degree relative of a carrier of such a gene mutation
 - family history consistent with a hereditary breast cancer syndrome and/or estimated personal lifetime cancer risk >25%
 - high-risk marker on prior biopsy (atypical ductal hyperplasia, atypical lobular hyperplasia, lobular carcinoma *in situ*)
 - radiation therapy to chest (before age 30)

Breast Interventional Procedures

Description

- includes fine needle aspirate biopsy, core needle biopsy, stereotactic biopsy, MRI guided biopsy, abscess drainage, and cyst aspiration (see General Surgery, GS59)

Indications

- cystic mass: complex cyst, symptomatic, suspected abscess
- solid mass: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5)
- suspicious calcifications: confirm diagnosis of a lesion suspicious for malignancy (BI-RADS® Category 4 or 5) – stereotactic biopsy
- initial percutaneous biopsy procedure that was insufficient or discordant with imaging
- presurgical wire localization of a lesion

Breast Findings

Breast Masses

- **definition:** a space-occupying lesion seen in two different projections; if seen in only a single projection it should be called an “asymmetry” until its three-dimensionality is confirmed

Table 21. Mammographic Features of Benign and Malignant Breast Masses

	Benign	Malignant
Shape	Oval, round, lobular	Irregular
Margin	Circumscribed, well-defined	Indistinct, microlobulated, spiculated
Density	Radiolucent (oil cyst, lipoma, fibrolipoma, galactocele, hamartoma)	Radiodense
Calcifications (± mass)	Popcorn (hyalinizing fibroadenoma), lucent centred (oil cyst/fat necrosis), layering (milk of calcium), vascular, round, scattered	Pleomorphic (vary in size and shape), amorphous (indistinct), fine linear, coarse heterogeneous, regional, segmental, clustered

Other Findings

- tubular density/dilated duct: branching tubular structures usually represent enlarged ducts (milk ducts); if they are clearly identified as such, these densities are of little concern
- intramammary lymph node: typical lymph nodes are circumscribed, reniform and often have a fatty notch and centre; usually less than 1 cm, and usually seen in the outer, often upper part of the breast; when these characteristics (particularly fatty centre or notch) are well seen, the lesion is almost always benign and insignificant
- focal asymmetry: area of breast density with similar shape on two views, but completely lacking borders and conspicuity of a true mass; must be carefully evaluated with focal compression to exclude findings of a true mass or architectural distortion
- if focal compression shows mass-like character – or if the area can be palpated – biopsy generally recommended

Basic Anatomy Review

Anatomy of the Kidney

- see [Urology, U2](#)

Renal Structure and Function

The Nephron

- basic structural and functional unit of the kidney, approximately 1 million per kidney
- 2 main components: glomerulus and attached renal tubule
- direction of blood flow: afferent arteriole → glomerular capillaries → efferent arteriole → vasa recta (the capillaries surrounding the tubules) → renal venules

Table 1. Major Kidney Functions

Function	Mechanism	Affected Elements
1. Waste Excretion	Glomerular filtration	Excretion of nitrogenous products of protein metabolism (urea, Cr)
	Tubular secretion	Excretion of organic acids (urate) and organic bases (Cr)
	Tubular catabolism	Breakdown and excretion of drugs (antibiotics, diuretics) and peptide hormones (most pituitary hormones, insulin, glucagon)
2. Electrolyte Balance and Osmoregulation	Tubular NaCl and water reabsorption	Controls volume status and osmolar balance
	Tubular K ⁺ secretion	Controls potassium concentration
	Tubular H ⁺ secretion	Acid-base balance
	HCO ₃ ⁻ synthesis and reabsorption	Acid-base balance
	Tubular Ca ²⁺ , Mg ²⁺ , PO ₄ ³⁻ transport	Alters Ca ²⁺ , Mg ²⁺ , PO ₄ ³⁻ homeostasis
	Synthesize osmolytes	Increase osmolality of medullary cytoplasm to match medullary concentration gradient
3. Hormonal Synthesis	Erythropoietin production (cortex)	Red blood cell production
	Vitamin D activation: 25(OH)VitD converted to 1,25(OH) ₂ VitD (proximal tubule)	Calcium homeostasis
	Renin production (juxtaglomerular apparatus)	Alters vascular resistance and aldosterone secretion
4. Blood Pressure Regulation	Na ⁺ excretion	Alters ECF volume
	Renin production	Alters vascular resistance
5. Glucose Homeostasis	Gluconeogenesis (from lactate, pyruvate, and amino acids)	Glucose supply maintained in prolonged starvation
	Clearance and degradation of circulating insulin	Maintains glucose homeostasis

The Glomerulus

- site where blood constituents are filtered through to the kidney tubules for excretion or reabsorption
- filtration occurs across the glomerular filtration barrier (endothelium, GBM, podocytes) into Bowman's space
- particles are selectively filtered by size (<60 kDa) and charge (negative charge repelled)

- consists of following cell types:
 1. Mesangial cells
 - structural cells that support the vascular tree; they are also contractile and produce vasoactive substances to help control blood flow
 2. Capillary endothelial cells
 - one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their sinusoidal nature and glycocalyx; contribute to the production of the GBM
 3. Visceral epithelium (podocytes)
 - one of the cells of the glomerular filtration barrier; help form the plasma filtration apparatus due to their interdigitated foot process that form slit diaphragms; contribute to the production of the GBM
 4. Parietal epithelium
 - lines the interior of Bowman's capsule and contains a podocyte progenitor population
 5. Juxtaglomerular cells
 - smooth muscle cells in lining of afferent arteriole; produce, store and secrete renin

Figure 2. Tubular segments of the nephron

Renal Hemodynamics

- GFR
 - GFR is the sum of the filtration across all nephrons
 - the rate of fluid transfer between glomerular capillaries and Bowman's space
 - average 180 L/d, of which 99% is reabsorbed, giving a urine output of 1.0-1.5 L/d to match oral fluid intake
 - normal urine output is 0.5-2.0 ml/kg/h in adults
 - GFR is highest in early adulthood, and decreases thereafter starting around age 40
- renal autoregulation maintains constant GFR over mean arterial pressures of 70-180 mmHg
- 2 mechanisms of autoregulation
 - myogenic mechanism: release of vasoactive factors such as prostaglandins in response to changes in perfusion pressure (e.g. → perfusion pressure → afferent arteriolar constriction → decreased GFR)
 - tubuloglomerular feedback: changes in Na⁺ delivery to macula densa lead to changes in afferent arteriolar tone (e.g. increased delivery causes afferent constriction)
- FF
 - percentage of RPF filtered across the glomeruli
 - expressed as a ratio: FF = GFR/RPF; normal = 0.2 or 20%
 - angiotensin II constricts renal efferent arterioles which increases FF, thereby maintaining GFR
- renin is released from juxtaglomerular apparatus in response to decreased RPF and maintain sodium balance
 - renin is an important enzyme in the renin angiotensin aldosterone system (RAAS), that converts angiotensinogen to angiotensin I

Glomerular Filtration Rate

$$GFR = K_f (\Delta P - \Delta \Pi)$$

K_f = ultrafiltration coefficient

ΔP = hydrostatic pressure difference between glomerular capillaries and Bowman's space

$\Delta \Pi$ = osmotic pressure difference between glomerular capillaries and Bowman's space

$\Delta P - \Delta \Pi$ = net outward pressure

Figure 3. Renin-angiotensin-aldosterone system

Assessment of Renal Function

Measurement of Renal Function

- clinically, GFR is estimated using serum creatinine concentration, [Cr]
- inulin clearance and iohalamate radiotracer is the gold standard for measuring GFR, but very rarely used clinically
- most renal functions decline in parallel with a decrease in GFR
- Cr is a metabolite of creatine (intermediate in muscle metabolism), therefore increased muscle mass increases Cr production
- Cr is freely filtered at the glomerulus with little tubular reabsorption
- tubular secretion of Cr varies based on level of renal function (10% to >50%)
- Cr filtered \approx Cr excreted (at steady state)

Ways to Estimate GFR Using Serum Creatinine Concentration

1. Measure CrCl
 - calculation provides reasonable estimate of GFR
 - ♦ $GFR/d = (\text{urine [Cr]} \times 24 \text{ h urine volume}) / (\text{plasma [Cr]})$
 - ♦ must use same units for urine [Cr] and plasma [Cr]
2. Estimate CrCl using Cockcroft-Gault formula
 - serum Cr used along with age, gender, and weight (kg) to estimate GFR (but does not include race)
 - overestimate GFR when renal function severely impaired
3. Estimate GFR using MDRD formula
 - most common way in which GFR is estimated (MDRD 7 equation)
 - complex formula incorporating age, gender, serum Cr, and race, but does not include weight
 - GFR is reported as mL/min/1.73 m² body surface area
 - underestimation of GFR at near normal values
4. Estimate GFR using CKD-EPI equation
 - the best current equation
 - calculated using serum Cr, age, sex, and race
 - overestimate GFR

Limitations of Using Serum Cr Measurements

1. must be in steady state
 - constant GFR and rate of production of Cr from muscles
 - sudden injury (e.g. AKI) may reduce GFR substantially, however, serum Cr will not immediately reflect sudden reduction in GFR until new Cr steady-state is reached
2. GFR must fall substantially before plasma [Cr] rises above normal laboratory range
 - with progressive renal failure, remaining nephrons compensate with hyperfiltration
 - GFR is relatively preserved despite significant structural damage
3. plasma [Cr] is influenced by the rate of Cr production
 - lower production with smaller muscle mass (e.g. female, elderly, low weight)
 - ♦ for example, consider plasma [Cr] of 100 $\mu\text{mol/L}$ in both of these patients
 - 20 yr old man who weighs 100 kg, GFR = 144 mL/min
 - 80 yr old woman who weighs 50 kg, GFR = 30.6 mL/min
 - clinical correlation: GFR decreases with age but would not be reflected as a rise in serum Cr due to the age-associated decline in muscle mass
4. tubular secretion of Cr increases as GFR decreases
 - serum Cr and CrCl overestimate low GFR
 - certain drugs (cimetidine, trimethoprim) interfere with Cr secretion
5. errors in Cr measurement
 - very high bilirubin level causes [Cr] to be falsely low
 - acetoacetate (a ketone body) and certain drugs (cefoxitin) create falsely high [Cr]

Measurement of Urea Concentration

- urea is the major end-product of protein metabolism
- plasma urea concentration reflects renal function but should not be used alone as it is modified by a variety of other factors
- urea production reflects dietary intake of protein and catabolic rate; increased protein intake or catabolism (sepsis, trauma, GI bleed) causes urea level to rise
- ECF volume depletion causes a rise in urea independent of GFR or plasma [Cr]
- in addition to filtration, a significant amount of urea is reabsorbed along the tubule
- reabsorption is increased in hypernatremic states
- typical ratio of urea to [Cr] in serum is 1:12 in SI units (using mmol/L for urea and $\mu\text{mol/L}$ for Cr)

$$Cr_{\text{filtered}} = Cr_{\text{excreted}}$$

$$[Cr]_{\text{plasma}} \times GFR = [Cr]_{\text{urine}} \times \text{urine flow rate (mL/min)}$$

$$GFR = \frac{[Cr]_{\text{urine}} \times \text{urine flow rate}}{[Cr]_{\text{plasma}}}$$

At steady state $[Cr]_{\text{serum}} \propto 1/CrCl$

Cockcroft-Gault Formula

$$CrCl \text{ (mL/min)} = \frac{(\text{weight in kg}) (140 - \text{age}) \times 1.23}{(\text{serum creatinine } (\mu\text{mol/L}))}$$

Multiply above by 0.85 for females

MDRD Equation

$$GFR \text{ (mL/min/1.73 m}^2) = 186 \times (S_{Cr})^{-1.154} \times (\text{Age})^{0.203} \times (0.742 \text{ if female}) \times (1.212 \text{ if African American})$$

Cystatin C

Cystatin C is a protease which is completely filtered by the glomerulus and is not affected by muscle mass; it is not currently used in clinical practice, but may be a more accurate way to measure renal function in the future, particularly in DM

Clinical Settings in which Urea Level is Affected Independent of Renal Function

Disproportionately High Urea

- Volume depletion (prerenal azotemia)
- GI hemorrhage
- High protein diet
- Sepsis
- Catabolic state with tissue breakdown
- Corticosteroid or cytotoxic agents

Disproportionately Low Urea

- Low protein diet
- Liver disease

Urinalysis

- use dipstick in freshly voided urine specimen to assess the following:

1. Specific Gravity

- ratio of the mass of equal volumes of urine/H₂O
- range is 1.001-1.030
- values <1.010 reflect dilute urine, values >1.020 reflect concentrated urine
- value usually 1.010 in ESRD (isosthenuria: same specific gravity as plasma)

2. pH

- urine pH is normally between 4.5-7.0; if persistently alkaline, consider
 - RTA
 - UTI with urease-producing bacteria (e.g. *Proteus*)

3. Glucose

- freely filtered at glomerulus and reabsorbed in proximal tubule
- causes of glucosuria include:
 1. hyperglycemia >9-11 mmol/L leads to filtration that exceeds tubular resorption capacity
 2. increased GFR (e.g. pregnancy)
 3. proximal tubule dysfunction (e.g. Fanconi's syndrome)

4. Protein

- dipstick only detects albumin; other proteins (e.g. Bence-Jones, Ig, Tamm-Horsfall) may be missed
- microalbuminuria (morning ACR of 2.0 - 20 mg/mmol) is not detected by standard dipstick, greater than these ranges would be macroalbuminuria (see *Diabetes, NP31*)
- sulfosalicylic acid detects all protein in urine by precipitation
- gold standard: 24 h timed urine collection for total protein

5. Leukocyte Esterase

- enzyme found in WBC and detected by dipstick
- presence of WBCs indicates infection (e.g. UTI) or inflammation (e.g. AIN)

6. Nitrites

- nitrates in urine are converted by some bacteria to nitrites
- high specificity but low sensitivity for UTI

7. Ketones

- positive in alcoholic/diabetic ketoacidosis, prolonged starvation, fasting

8. Hemoglobin

- positive in hemoglobinuria (hemolysis), myoglobinuria (rhabdomyolysis), and true hematuria (RBCs seen on microscopy)

Estimating Urine Osmolality

Last 2 digits of the specific gravity x 30 = urine osmolality approximately (e.g. specific gravity of 1.020 = 600 mOsm)

24 h Urine Collection

- Discard first morning specimen
- Collect all subsequent urine for the next 24 h
- Refrigerate between voids
- Collect second morning specimen and take to lab immediately

Positive dipstick for leukocyte esterase and nitrites is highly specific for diagnosing a UTI

Nitrite Negative Bacteria

- *Enterococci*
- *Staphylococci*

Nitrite Positive Bacteria

- *Enterobacteriaceae* (e.g. *E. coli*)

Urine Microscopy

Table 2. Comparison of Urinary Sediment Findings

	Active Sediment = Suggestive of Parenchymal Kidney Disease	Bland Sediment = Less Likely Parenchymal Kidney Disease
Any one or more of the following seen on microscopy	Red cell casts White cell casts Muddy-brown granular or epithelial cell casts >2 red cells per HPF >4 white cells per HPF	Only hyaline casts Small quantities of crystals Small amount of bacteria <2 red cells per HPF <4 white cells per HPF

1. CELLS

Erythrocytes

- hematuria = greater than normal range of 2-3 RBCs per HPF
- dysmorphic RBCs and/or RBC casts suggest glomerular bleeding (e.g. proliferative GN)
- isomorphic RBCs, no casts suggest extraglomerular bleeding (e.g. bladder Ca)

Leukocytes

- pyuria = greater than upper limit of normal: 3 WBCs per HPF
- indicates inflammation or infection
- if persistent sterile pyuria present (i.e. negative culture), consider: chronic urethritis, prostatitis, interstitial nephritis, calculi, papillary necrosis, renal TB, viral infections

Eosinophils

- detected using Wright's or Hansel's stain (not affected by urine pH)
- consider AIN, atheroembolic disease

Oval Fat Bodies

- renal tubular cells filled with lipid droplets
- seen in heavy proteinuria (e.g. nephrotic syndrome)

2. CASTS

- cylindrical structures formed by intratubular precipitation of Tamm-Horsfall mucoprotein; cells may be trapped within the matrix of protein

Table 3. Interpretation of Casts

Cast	Interpretation
Hyaline casts	Physiologic (concentrated urine, fever, exercise)
RBC casts	Glomerular bleeding (GN, vasculitis)
WBC casts	Infection (pyelonephritis) Inflammation (interstitial nephritis)
Pigmented granular casts (heme granular casts, muddy brown)	ATN Acute GN
Fatty casts	Nephrotic Syndrome (>3.5 g/d)

3. CRYSTALS

- uric acid: consider acid urine, hyperuricosuria
- calcium phosphate: alkaline urine
- calcium oxalate: consider hyperoxaluria, ethylene glycol poisoning
- sulfur: sulfa-containing antibiotics

Urine Biochemistry

- commonly measure: Na^+ , K^+ , Cl^- , osmolality, and pH
- no "normal" values; electrolyte excretion depends on intake and current physiological state
- results must be interpreted in the context of a patient's current state, for example:
 - ECF volume depletion: expect low urine $[\text{Na}^+]$ (kidneys should be retaining Na^+)
 - urine $[\text{Na}^+] > 20$ mmol/L suggests a renal problem or the action of a diuretic
 - urine $[\text{Na}^+] < 20$ mmol/L suggests a prerenal problem
 - daily urinary potassium excretion rate should be decreased (< 20 mmol/d) in hypokalemia
 - if higher than 20 mmol/d, suggests renal contribution to hypokalemia
- osmolality is useful to estimate the kidney's concentrating ability
- FE_{Na} refers to the fractional excretion of Na^+
 - $\text{FE}_{\text{Na}} < 1\%$ suggests the pathology is prerenal
- urine pH is useful to grossly assess renal acidification
 - low pH (< 5.5) in the presence of low serum pH is an appropriate renal response
 - a high pH in this setting might indicate a renal acidification defect (e.g. RTA)

Fractional Excretion of Sodium

$$\text{FE}_{\text{Na}} = \frac{[\text{Na}^+]_{\text{urine}} \times [\text{Cr}]_{\text{plasma}}}{[\text{Na}^+]_{\text{plasma}} \times [\text{Cr}]_{\text{urine}}} \times 100$$

Electrolyte Disorders

Sodium Homeostasis

- hyponatremia and hypernatremia are disorders of water balance
 - hyponatremia usually suggests too much water in the ECF relative to Na^+ content
 - hypernatremia usually suggests too little water in the ECF relative to Na^+ content
- solutes (such as Na^+ , K^+ , glucose) that cannot freely traverse the plasma membrane contribute to effective osmolality and induce transcellular shifts of water
 - water moves out of cells in response to increased ECF osmolality
 - water moves into cells in response to decreased ECF osmolality
- ECF volume is determined by Na^+ content rather than concentration
 - Na^+ deficiency leads to ECF volume contraction
 - Na^+ excess leads to ECF volume expansion
- clinical signs and symptoms of hyponatremia and hypernatremia are secondary to cells (especially in the brain) shrinking (hypernatremia) or swelling (hyponatremia)

Table 4. Clinical Assessment of ECF Volume (Total Body Na⁺)

Fluid Compartment	Hypovolemic	Hypervolemic
Intravascular		
JVP	Decreased	Increased
Blood pressure	Orthostatic drop	Normal to increased
Auscultation of heart	Tachycardia	S3
Auscultation of lungs	Normal	Inspiratory crackles
Interstitial		
Skin turgor	Decreased	Normal/increased
Edema (dependent)	Absent	Present
Other		
Urine output	Decreased*	Variable
Body weight	Decreased	Increased
Hematocrit, serum protein	Increased	Decreased

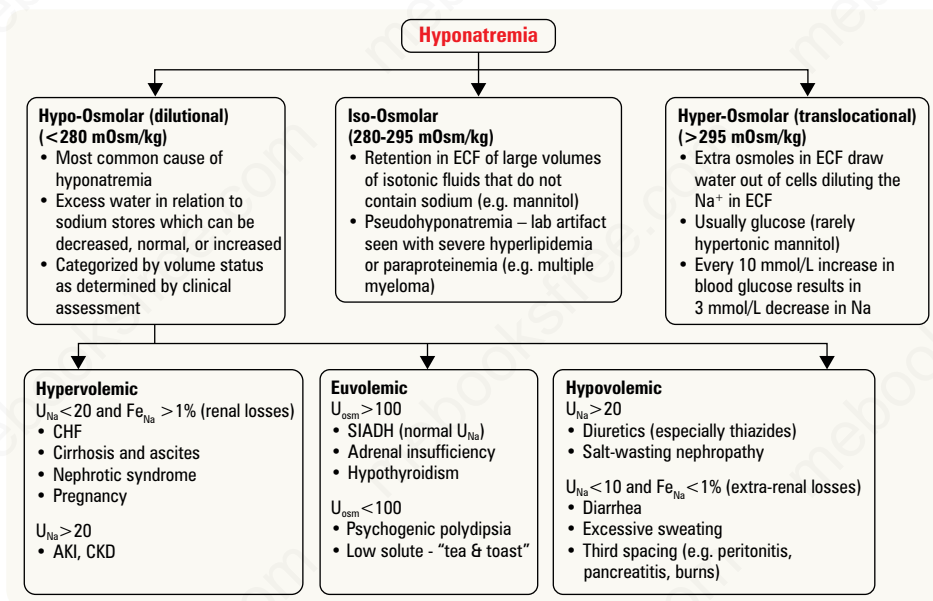

*If there is a renal abnormality (e.g. osmotic diuresis), the urine output may be increased despite the presence of hypovolemia

Hyponatremia

- hyponatremia: serum [Na⁺] <135 mmol/L
- can be associated with hypo-osmolality (most common), iso-osmolality, or hyperosmolality
- consider if it is “appropriate” vs. “inappropriate” ADH secretion
- if appropriate ADH secretion, is it real vs. effective volume loss?

If the urine osmolality is unknown, assume the urine is hypo-osmolar/dilute

**Figure 4. Approach to hyponatremia**

Signs and Symptoms

- depend on degree of hyponatremia and more importantly, velocity of progression from onset
- hyponatremia = swollen cells
- acute hyponatremia (<24-48 h) more likely to be symptomatic
- chronic hyponatremia (>24-48 h) less likely to be symptomatic due to adaptation
 - adaptation: normalization of brain volume through loss of cellular electrolytes (within hours) and organic osmolytes (within days)
- adaptation is responsible for the risks associated with overly rapid correction
- neurologic symptoms predominate (secondary to cerebral edema): headache, nausea, malaise, lethargy, weakness, muscle cramps, anorexia, somnolence, disorientation, personality changes, depressed reflexes, decreased LOC

Complications

- seizures, coma, respiratory arrest, permanent brain damage, brainstem herniation, death
- risk of brain cell shrinkage with rapid correction of hyponatremia
 - can develop osmotic demyelination of pontine and extrapontine neurons; may be irreversible (e.g. central pontine myelinolysis: cranial nerve palsies, quadriplegia, decreased LOC)

Symptoms of Central Pontine Myelinolysis

- Cranial nerve palsies
- Quadriplegia
- Decreased LOC

Risk Factors for Osmotic Demyelination

- rise in serum $[Na^+]$ with correction >8 mmol/L/24 hr if chronic hyponatremia
- associated hypokalemia and/or malnutrition (e.g. low muscle mass)
- if patient with hyponatremia and hypovolemia is given large volume of isotonic fluid (ADH is stimulated by hypovolemia; when hypovolemia is corrected, the ADH level falls suddenly causing sudden brisk water diuresis, and therefore rapid rise in serum Na^+ level)
- patient with psychogenic polydipsia, deprived of water

Investigations

- ECF volume status assessment (see Table 4)
- serum electrolytes, glucose, Cr
- serum osmolality, urine osmolality
- urine Na^+ (urine $Na^+ <10-20$ mmol/L suggests volume depletion as the cause of hyponatremia)
- assess for causes of SIADH (see Table 5)
- TSH, free T4, and cortisol levels
- consider CXR and possibly CT chest if suspect pulmonary cause of SIADH (e.g. paraneoplastic syndrome by small cell lung cancer)
- consider CT head if suspect CNS cause of SIADH

Treatment of Hyponatremia

- general measures for all patients
 1. treat underlying cause (e.g. restore ECF volume if volume depleted, remove offending drug, treat pain, nausea, etc.)
 2. restrict free water intake
 3. promote free water loss
 4. carefully monitor serum Na^+ , urine volume, and urine tonicity
 5. ensure frequently that correction is not occurring too rapidly
 - ♦ monitor urine output frequently: high output of dilute urine is the first sign of dangerously rapid correction of hyponatremia

A. Known Acute (known to have developed over $<24-48$ h)

- commonly occurs in hospital (dilute IV fluid, post-operative increased ADH)
- less risk from rapid correction since adaptation has not fully occurred
- if symptomatic
 - correct rapidly with 3% NaCl 1-2 cc/kg/h up to serum $[Na^+] = 125-130$ mmol/L
 - may need furosemide to address volume overload
- if asymptomatic, treatment depends on severity
 - if marked fall in plasma $[Na^+]$, treat as symptomatic

B. Chronic or Unknown

1. if severe symptoms (seizures or decreased LOC)
 - ♦ must partially correct acutely
 - ♦ aim for increase of Na^+ by 0.5-1 mmol/L/h for 4-6 h
 - ♦ limit total rise to 8 mmol/L in 24 h
 - ♦ IV 3% NaCl at 1-2 cc/kg/h
 - ♦ may need furosemide
2. if asymptomatic
 - ♦ water restrict to <1 L/d fluid intake
 - ♦ consider IV 0.9% NS + furosemide (reduces urine osmolality, augments excretion of H_2O)
 - ♦ consider NaCl tablet or Oxocubes[®] as a source of Na^+
3. refractory
 - ♦ furosemide and oral salt tablets
 - ♦ oral urea (osmotic aquaresis)
 - ♦ V2 receptor antagonists (e.g. tolvaptan)
4. always pay attention to patient's ECF volume status – if already volume-expanded, unlikely to give NaCl (tablet or IV); if already volume-depleted, almost never appropriate to give furosemide

C. Options for Treatment of Overly-Rapid Correction

- give water (IV D5W)
- give ADH to stop water diuresis (DDAVP 1-2 μ g IV)

Impact of IV Solution on Serum $[Na^+]$

- formula to estimate the change in serum $[Na^+]$ caused by retention of 1 L of any infusate
 $[TBW = (\text{for men}) 0.6 \times \text{wt}(\text{kg}); (\text{for women}) 0.5 \times \text{wt}(\text{kg})]$

$$\text{change in serum } [Na^+] = \frac{\text{infusate } [Na^+] - \text{serum } [Na^+]}{TBW + 1 \text{ L}}$$

- formula assumes there are no losses of water or electrolytes

Beware of Rapid Correction of Hyponatremia

- Inadvertent rapid correction of hyponatremia can easily occur (e.g. patient with hyponatremia due to SIADH from nausea)
- Anti-emetic given for relief of hyponatremia-induced nausea
- ADH quickly turned off in the absence of nausea, the kidneys rapidly excrete the excess free water, and the serum $[Na^+]$ rises rapidly
- Patient at risk of osmotic demyelination
- High output dilute urine (>100 cc/h, <100 mOsm/L) in the setting of hyponatremia is usually the first sign of dangerously rapid correction of serum sodium

Correction of Na^+ in hyponatremia should not exceed 8 mmol/L/24 h unless definitely known to be $<24-48$ h duration; frequent monitoring of serum Na^+ and urine output is essential

Concentration of $[Na^+]$ in Common Infusates

- $[Na^+]$ in 0.45% NaCl = 77 mmol/L
- $[Na^+]$ in 0.9% NaCl = 154 mmol/L
- $[Na^+]$ in 3% NaCl = 513 mmol/L
- $[Na^+]$ in 5% NaCl = 855 mmol/L
- $[Na^+]$ in Ringer's lactate = 130 mmol/L
- $[Na^+]$ in D5W = 0

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE SECRETION

1. urine that is inappropriately concentrated for the serum osmolality
2. high urine sodium (>20-40 mmol/L)
3. high FE_{Na}

Table 5. Disorders Associated with SIADH

Cancer	Pulmonary	CNS	Drugs	Miscellaneous
Small cell cancer	Pneumonia	Mass lesion	Antidepressants	Post-operative state
Bronchogenic carcinoma	Lung abscess	Encephalitis	TCAs	Pain
Pancreatic adenocarcinoma	TB	Subarachnoid hemorrhage	SSRIs	Severe nausea
Hodgkin's lymphoma	Acute respiratory failure	Stroke	Antineoplastics	HIV
Thymoma	Asthma	Head trauma	Vincristine	
Leukemia	COPD	Acute psychosis	Cyclophosphamide	
	Positive pressure ventilation	Acute intermittent porphyria	Anti-epileptics	
			Carbamazepine	
			Barbiturates	
			Chlorpropamide	
			ACEI	
			Other	
			DDAVP	
			Oxytocin	
			Nicotine	

Hypernatremia

- hypernatremia: serum [Na⁺] >145 mmol/L
- too little water relative to total body Na⁺; always a hyperosmolar state
- usually due to NET water loss, rarely due to hypertonic Na⁺ gain
- less common than hyponatremia because patients are protected against hypernatremia by thirst and release of ADH

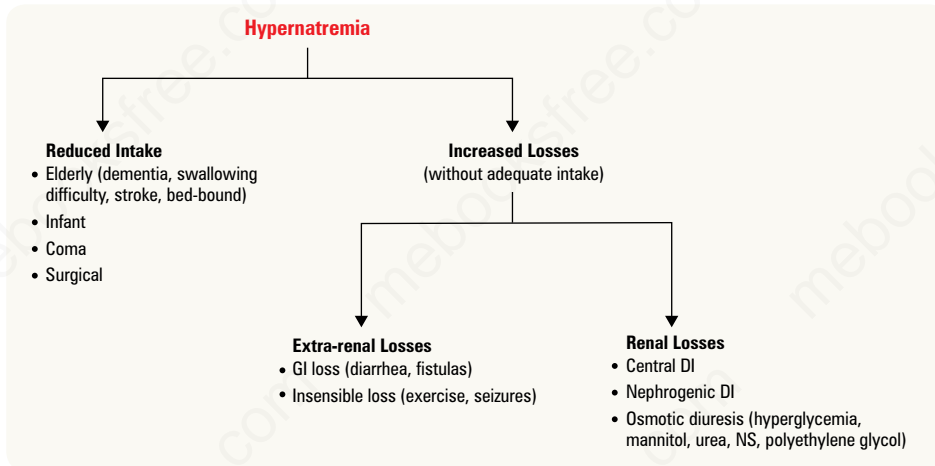

Figure 5. Approach to hypernatremia

Signs and Symptoms

- with acute hypernatremia there is no time for adaptation, therefore more likely to be symptomatic
- adaptive response: cells import and generate new osmotically active particles to normalize size
- due to brain cell shrinkage: altered mental status, weakness, neuromuscular irritability, focal neurologic deficits, seizures, coma, death
- ± polyuria, thirst, signs of hypovolemia

Complications

- increased risk of vascular rupture resulting in intracranial hemorrhage
- rapid correction may lead to cerebral edema due to ongoing brain hyperosmolality

Treatment of Hypernatremia

- general measures for all patients
 - give free water (oral or IV)
 - treat underlying cause
 - monitor serum Na⁺ frequently to ensure correction is not occurring too rapidly
- if evidence of hemodynamic instability, must first correct volume depletion with NS bolus
- loss of water is often accompanied by loss of Na⁺, but a proportionately larger water loss
- use formula to calculate free water H₂O deficit and replace
- encourage patient to drink pure water, as oral route is preferred for fluid administration

H₂O Deficit and TBW Equations

$TBW = 0.6 \times wt \text{ (kg) men}$
 $TBW = 0.5 \times wt \text{ (kg) women}$

$H_2O \text{ deficit} = TBW \times ([Na^+]_{\text{plasma}} - 140) / 140$

Correction of serum [Na⁺] in hypernatremia should not exceed 12 mmol/L/24 h

1 L D5W approximately equals 1 L of free water
 1 L 0.45% NS approximately equals 500 mL of free water

- if unable to replace PO or NG, correct H₂O deficit with hypotonic IV solution (IV D5W, 0.45% NS [half normal saline], or 3.3% dextrose with 0.3% NaCl [^{2/3} and ^{1/3}])
- use formula (see *Hyponatremia, NP8*) to estimate expected change in serum Na⁺ with 1 L infusate
- aim to lower [Na⁺] by no more than 12 mmol/L in 24 h (0.5 mmol/L/h)
- must also provide maintenance fluids and replace ongoing losses
- general rule: give 2 cc/kg/h of free water to correct serum [Na⁺] by about 0.5 mmol/L/h or 12 mmol/L/d

Diabetes Insipidus

- collecting tubule is impermeable to water due to absence of ADH or impaired response to ADH
- defect in central release of ADH (central DI) or renal response to ADH (nephrogenic DI)

Etiology

- central DI: neurosurgery, granulomatous diseases, trauma, vascular events, and malignancy
- nephrogenic DI: lithium (most common), hypokalemia, hypercalcemia, and congenital

Diagnosis

- urine osmolality inappropriately low in patient with hypernatremia (U_{osm} <300 mOsm/kg)
- serum vasopressin concentration may be absent or low (central), or elevated (nephrogenic)
- dehydration test: H₂O deprivation until loss of 3% of body weight or until urine osmolality rises above plasma osmolality; if urine osmolality remains <300 (fails to concentrate urine), most likely DI
- administer DDAVP (exogenous ADH) (10 µg intranasally or 2 µg SC or IV)
 - central DI: diagnosed if there is rise in urine osmolality, fall in urine volume
 - ♦ treat with DDAVP
 - nephrogenic DI: exogenous ADH fails to concentrate urine as kidneys do not respond
 - ♦ treat with water (IV D5W or PO water), thiazides may help as well (reduced ECF volume stimulates proximal tubular reabsorption of sodium and water, leading to less delivery of glomerular filtrate to ADH sensitive parts of renal tubule, and therefore lower urine volume results)

Potassium Homeostasis

- approximately 98% of total body K⁺ stores are intracellular
- normal serum K⁺ ranges from 3.5-5.0 mEq/L
- in response to K⁺ load, rapid removal from ECF is necessary to prevent life-threatening hyperkalemia
- insulin, catecholamines, and acid-base status influence K⁺ movement into cells
 - aldosterone has a minor effect
- potassium excretion is regulated at the distal nephron
 - K⁺ excretion = urine flow rate x urine [K⁺]

Factors which Increase Renal K⁺ Loss

- hyperkalemia
- increased distal tubular urine flow rate and Na⁺ delivery (thiazides and loop diuretics)
- increased aldosterone activates epithelial sodium channels in cortical collecting duct, causing Na⁺ reabsorption and K⁺ excretion
- metabolic alkalosis (increases K⁺ secretion)
- hypomagnesemia
- increased non-reabsorbable anions in tubule lumen: HCO₃⁻, penicillin, salicylate (increased tubular flow rate increases K⁺ secretion)

Hypokalemia

- serum [K⁺] <3.5 mEq/L

Signs and Symptoms

- usually asymptomatic, particularly when mild (3.0-3.5 mmol/L)
- N/V, fatigue, generalized weakness, myalgia, muscle cramps, and constipation
- if severe: arrhythmias, muscle necrosis, and rarely paralysis with eventual respiratory impairment
- arrhythmias occur at variable levels of K⁺; more likely if digoxin use, hypomagnesemia, or CAD
- ECG changes are more predictive of clinical picture than serum [K⁺]
 - U waves most important (low amplitude wave following a T wave)
 - flattened or inverted T waves
 - depressed ST segment
 - prolongation of Q-T interval
 - sinus bradycardia
 - with severe hypokalemia: P-R prolongation, wide QRS, arrhythmias; increases risk of digitalis toxicity
 - common arrhythmias seen with hypokalemia: Ventricular fibrillation, Ventricular tachycardia's

Figure 6. ECG changes in hypokalemia

Approach to Hypokalemia

1. emergency measures: obtain ECG; if potentially life threatening, begin treatment immediately
2. rule out transcellular shifts of K^+ as cause of hypokalemia
3. assess contribution of dietary K^+ intake
4. spot urine K:Cr (should be less than 1 in setting of hypokalemia)
 - if <1 consider GI loss
 - if >1 consider a renal loss
5. consider 24 h K^+ excretion
6. if renal K^+ loss, check BP and acid-base status
7. may also assess plasma renin and aldosterone levels, serum $[Mg^{2+}]$

- Hypokalemia often accompanied by metabolic alkalosis
- Potassium leaves cells, replaced by H^+
- Kidney tubular cells see high H^+ , think acidosis and increase ammonium synthesis and excretion
- Increase in bicarbonate generation

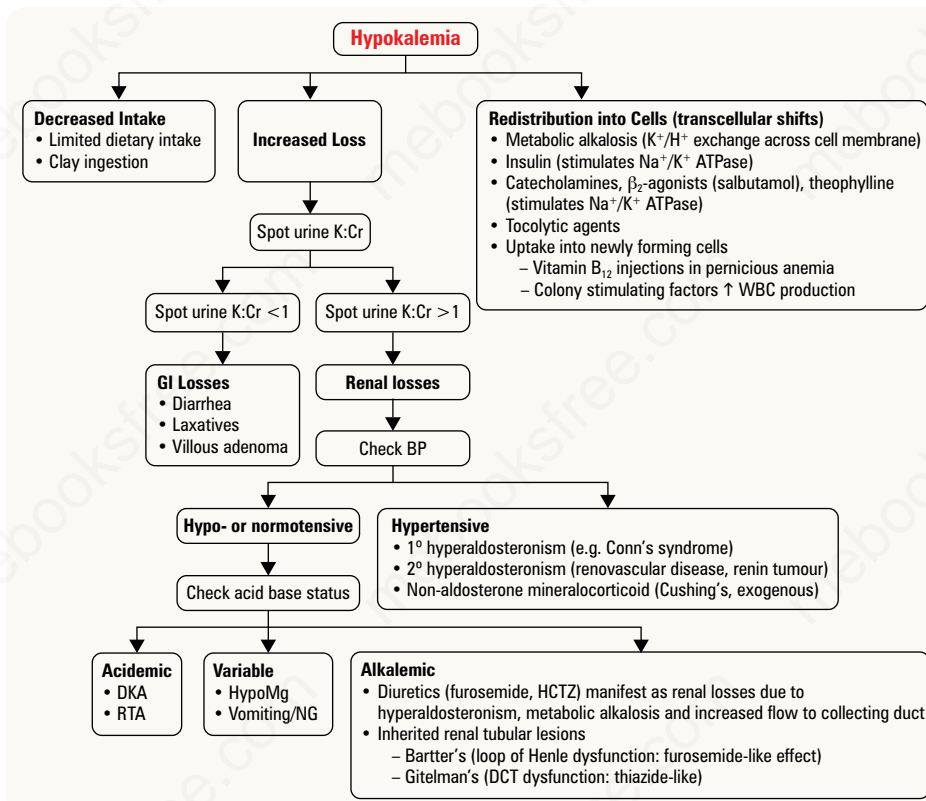

Figure 7. Approach to hypokalemia

Treatment

- treat underlying cause
- if true K^+ deficit, potassium repletion
 - oral sources – food, tablets (K-Dur™), KCl liquid solutions (preferable route if the patient tolerates PO medications)
 - IV – usually KCl in saline solutions, avoid dextrose solutions (may exacerbate hypokalemia via insulin release)
- max 40 mmol/L via peripheral vein, 60 mmol/L via central vein, max infusion 20 mmol/h
- K^+ -sparing diuretics (triamterene, amiloride, spironolactone) can prevent renal K^+ loss
- restore Mg^{2+} if necessary
- if urine output and renal function are impaired, correct with extreme caution
- risk of hyperkalemia with potassium replacement especially high in elderly, diabetics, and patients with decreased renal function
- use of ACE inhibitor or ARB for CHF (reduces angiotensin II action and therefore aldosterone)
- beware of excessive potassium repletion, especially if transcellular shift caused hypokalemia

Hyperkalemia

- serum $[K^+] > 5.0$ mEq/L

Signs and Symptoms

- usually asymptomatic but may develop nausea, palpitations, muscle weakness, muscle stiffness, paresthesias, areflexia, ascending paralysis, and hypoventilation
- impaired renal ammoniogenesis and metabolic acidosis
- ECG changes and cardiotoxicity (do not correlate well with serum $[K^+]$)
- peaked and narrow T waves
- decreased amplitude and eventual loss of P waves
- prolonged PR interval
- widening of QRS and eventual merging with T wave (sine-wave pattern)
- AV block
- ventricular fibrillation, asystole

Figure 8. ECG changes in hyperkalemia

Table 6. Causes of Hyperkalemia

Factitious	Increased Intake	Transcellular Shift	Decreased Excretion
Sample hemolysis* Sample taken from vein where IV KCl is running Prolonged use of tourniquet Leukocytosis (extreme) Thrombocytosis (extreme)	Diet KCl tabs IV KCl Salt substitute	Intravascular hemolysis Rhabdomyolysis Tumour lysis syndrome Insulin deficiency Acidemia Drugs β-blockers Digitalis overdose (blocks Na^+/K^+ ATPase) Succinylcholine	Decreased GFR Renal failure Low effective circulating volume NSAIDs in renal insufficiency Normal GFR but hypoaldosteronism

*Most common

Table 7. Causes of Hyperkalemia with Normal GFR

Decreased Aldosterone Stimulus (low renin, low aldosterone)	Decreased Aldosterone Production (normal renin, low aldosterone)	Aldosterone Resistance (decreased tubular response)
Associated with diabetic nephropathy, NSAIDs, chronic interstitial nephritis, HIV	Adrenal insufficiency of any cause (e.g. Addison's disease, AIDS, metastatic cancer) ACEI Angiotensin II receptor blockers Heparin Congenital adrenal hyperplasia with 21-hydroxylase deficiency	K^+ -sparing diuretics Spironolactone Amiloride Triamterene Renal tubulointerstitial disease

Approach to Hyperkalemia

- emergency measures: obtain ECG, if life threatening begin treatment immediately
- rule out factitious hyperkalemia; repeat blood test
- hold exogenous K^+ (PO and IV) and any K^+ retaining medications
- assess potential causes of transcellular shift
- estimate GFR (calculate CrCl using Cockcroft-Gault)

Treatment

- acute therapy is warranted if ECG changes are present or if patient is symptomatic regardless of $[K^+]$
- tailor therapy to severity of increase in $[K^+]$ and ECG changes
 - $[K^+] < 6.5$ and normal ECG
 - treat underlying cause, stop K^+ intake, increase the loss of K^+ via urine and/or GI tract
 - $[K^+]$ between 6.5 and 7.0, no ECG changes: add insulin to above regimen
 - $[K^+] > 7.0$ and/or ECG changes: first priority is to protect the heart, add calcium gluconate to above

1. Stabilize Myocardium

- calcium gluconate 1-2 amps (10 mL of 10% solution) IV
- antagonizes the membrane action of hyperkalemia, protects cardiac conduction system, no effect on serum $[K^+]$
- onset within minutes, lasts 30-60 min (may require repeat doses during treatment course of hyperkalemia)

In patients with DM and increased $[K^+]$ and hyperglycemia, often just giving insulin to restore euglycemia is sufficient to correct the hyperkalemia

Treatment of Hyperkalemia

C BIG K DROP
C – Calcium gluconate
BIG – β-agonist, Bicarbonate, Insulin, Glucose
K – Kayexalate®
DROP – Diuretics, Dialysis

2. Shift K⁺ into Cells

- regular insulin (Insulin R) 10-20 units IV, with 1-2 amp D50W (give D50W before insulin)
 - onset of action 15-30 min, lasts 1-2 h
 - monitor capillary blood glucose q1h because of risk of hypoglycemia
 - can repeat every 4-6 h
 - caution giving D50W before insulin if hyperkalemia is severe as it can cause a serious arrhythmia
- NaHCO₃ 1-3 ampules (given as 3 ampules of 7.5% or 8.4% NaHCO₃ in 1L D5W)
 - onset of action 15-30 min, transient effect, drives K⁺ into cells in exchange for H⁺
 - more effective if patient has metabolic acidosis
- β₂-agonist (Ventolin[®]) in nebulized form (dose = 2 cc or 10 mg inhaled) or 0.5 mg IV
 - onset of action 30-90 min, stimulates Na⁺/K⁺ ATPase
 - caution if patient has heart disease as may result in tachycardia

3. Enhance K⁺ Removal from Body

- via urine (preferred approach)
 - furosemide (≥40 mg IV), may need IV NS to avoid hypovolemia
 - fludrocortisone (synthetic mineralocorticoid) if suspect aldosterone deficiency
- via gastrointestinal tract
 - cation-exchange resins: calcium resonium or sodium polystyrene sulfonate (Kayexalate[®])
 - increasingly falling out of favour due to risk of colonic necrosis; works by binding Na⁺ in exchange for K⁺, and controversial how much K⁺ is actually removed
 - lactulose or sorbitol PO to avoid constipation (must ensure that patient has a bowel movement after resin is administered - main benefit may be the diarrhea caused by lactulose)
 - Kayexalate[®] enemas with tap water
- dialysis (renal failure, life threatening hyperkalemia unresponsive to therapy)

Management of Patients with Acute Hyperkalemia

CMAJ 2010;182:1631-1635

Purpose: To review the evidence supporting different treatment options for acute hyperkalemia.

Study: Systematic review of updated research since 2005 Cochrane review, search 200⁺ 2009 inclusive.

Results: Four new articles continued to support the acute usage of insulin and beta-agonists for shifting, and hemodialysis for elimination in severe and refractory hyperkalemia. One small randomized study comparing resins to laxatives was identified by the reviewers. It found no significant difference in serum potassium of the two groups in the 4 hours following administration. Study design was reportedly flawed; the resin group as a whole had lower initial serum concentration than the laxative control group.

Conclusion: Standard of care continues to include insulin, beta-agonists, and hemodialysis. There is no clear evidence supporting the use of resins, such as Kayexalate, for the acute management of hyperkalemia. Furthermore, prior studies have shown that resin usage can result in bowel obstruction and bowel necrosis.

Hyperphosphatemia

Definition

- serum phosphate >1.45 mmol/L
- critical role in the development of secondary hyperparathyroidism and renal osteodystrophy in patients with advanced CKD and on dialysis

Table 8. Etiology of Hyperphosphatemia

Increased Phosphate Load	Reduced Renal Clearance	Pseudohyperphosphatemia
GI intake (rectal enema, GI bleeding) IV phosphate load (K-Phos [®] , blood transfusion) Endogenous phosphate (tumour lysis syndrome, rhabdomyolysis, hemolysis, lactic and ketoacidosis)	Acute/chronic renal failure Hypoparathyroidism Acromegaly Tumour calcinosis (ability of kidney to specifically clear phosphate is defective)	Hyperglobulinemia Hyperlipidemia Hyperbilirubinemia

Clinical Features

- non-specific, include ectopic calcification, renal osteodystrophy

Treatment

- acute: hemodialysis if symptomatic ; aluminum hydroxide (use with extreme caution in renal failure)
- chronic: low PO₄³⁻ diet, phosphate binders (e.g. CaCO₃ or lanthanum carbonate or sevelamer with meals)

Hypophosphatemia

Definition

- serum phosphate <0.85 mmol/L

Table 9. Etiology of Hypophosphatemia

Inadequate Intake	Renal Losses	Excessive Skeletal Mineralization	Shift into ICF
Starvation Malabsorption (diarrhea, steatorrhea) Antacid use Alcoholism	Hyperparathyroidism Diuretics X-linked or AD hypophosphatemic rickets Fanconi syndrome Multiple myeloma Early post-kidney transplant	Osteoblastic metastases Post parathyroidectomy (referred to as 'hungry bone syndrome')	Recovery from metabolic acidosis Respiratory alkalosis Starvation refeeding (stimulated by insulin)

Symptoms usually present when phosphate <0.32 mmol/L (1.0 mg/dL)
Treat asymptomatic patients if phosphate <0.32 mmol/L

Severe burns can cause hypophosphatemia due to PO₄³⁻ losses through the skin

Clinical Features

- non-specific (CHF, coma, hypotension, weakness, defective clotting)

Treatment

- treat underlying cause
 - Oral PO_4^{3-} : 2-4 g/d divided bid-qid (start at 1 g/d to minimize diarrhea)
 - IV PO_4^{3-} : only for severely symptomatic patients or inability to tolerate oral therapy

Hypermagnesemia**Definition**

- serum magnesium >0.85 mmol/L

Etiology

- AKI/CRF
- Mg^{2+} -containing antacids or enemas
- IV administration of large doses of MgSO_4 (e.g. for *Preeclampsia*; see *Obstetrics*, OB24)

**Clinical Features**

- rarely symptomatic
- drowsiness, hyporeflexia, respiratory depression, heart block, cardiac arrest, hypotension

Treatment

- discontinue Mg^{2+} -containing products
- IV calcium (Mg^{2+} -antagonist) for acute reversal of magnesium toxicity
- dialysis if renal failure

Hypomagnesemia**Definition**

- serum magnesium <0.70 mmol/L

Etiology

GI losses	Excess renal loss
Starvation/malabsorption	2° hyperaldosteronism due to cirrhosis and CHF
Vomiting/diarrhea	Hyperglycemia
Alcoholism	Hypokalemia
Acute pancreatitis	Hypercalcemia
	Loop and thiazide-type diuretics
	Nephrotoxic medications
	Proton-pump inhibitors
	Early post-renal transplant

Clinical Features

- seizures, paresis, Chvostek and Trousseau signs, ECG changes (widened QRS, prolonged PR, T-wave abnormalities), and arrhythmias including Torsades de Pointes

Treatment

- treat underlying cause
- **encourage increased dietary intake e.g. fruits**
- oral Mg^{2+} salts unless patient has seizures or other severe symptoms
- Mg^{2+} IM/IV; cellular uptake of Mg^{2+} is slow, therefore repletion requires sustained correction
- discontinue diuretics
 - in patients requiring diuretics, use a K^+ -sparing diuretic to minimize magnesuria

You will be unable to correct hypokalemia or hypocalcemia without first supplementing magnesium if patient is hypomagnesemic

Acid-Base Disorders

- acid-base homeostasis influences protein function and can critically affect tissue and organ function with consequences to cardiovascular, respiratory, metabolic, and CNS function
- see *Respirology*, R6 for more information on respiratory acidosis/alkalosis
- normal concentration of HCO_3^- = 24 mEq/L (range: 22-30 mEq/L)
- normal pCO_2 = 40 mmHg (range: 36-44 mmHg)
- each acid base disorder has an appropriate compensation
 - inadequate compensation or overcompensation can indicate the presence of a second acid-base disorder (e.g. in metabolic acidosis, inadequate compensation means there is also respiratory acidosis; overcompensation means there is also respiratory alkalosis)

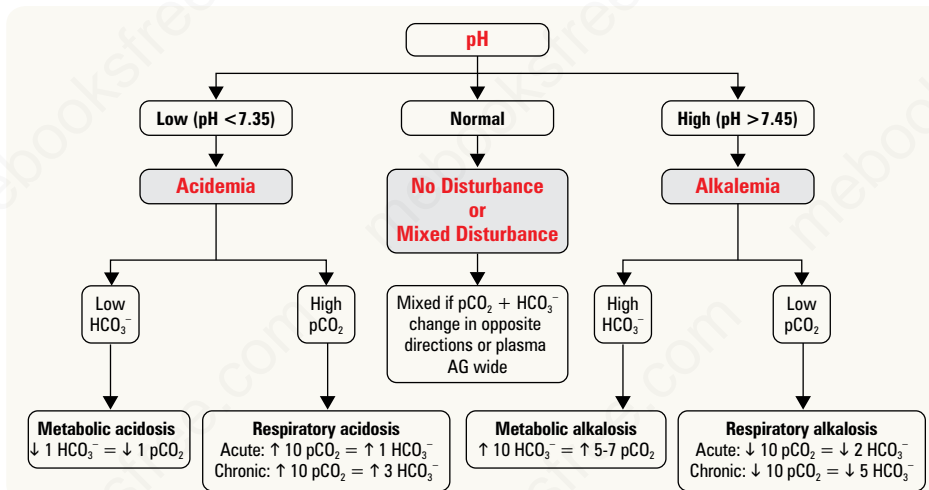

Figure 9. Approach to acid-base disorders

Approach

1. Identify the primary disturbance

- respiratory acidosis, metabolic acidosis, respiratory alkalosis, metabolic alkalosis

2. Evaluate compensation. If compensation is not appropriate, a second acid-base disorder is likely present

- compensation occurs in the same direction as the primary disturbance

3. Calculate Plasma AG

- $AG = [Na^+] - ([HCO_3^-] + [Cl^-])$
- baseline = 12, normal range 10-14 mEq/L
- AG can be altered by plasma albumin level: for each 10 g/L fall in albumin, lower baseline AG by 3 mEq/L (e.g. if plasma [albumin] = 20 g/L, expect AG = 6 mEq/L)

4. If AG elevated, compare increase in AG with decrease in HCO_3^-

- if increase in AG < decrease in HCO_3^- , there is a coexisting non-AG metabolic acidosis
- if increase in AG > decrease HCO_3^- , there is a coexisting metabolic alkalosis

5. Calculate Osmolar Gap

- osmolar gap = measured osmolality – calculated osmolality
 - calculated osmolality = $(2 \times [Na^+]) + [urea] + [glucose]$ (all units are in mmol/L)
 - normal osmolar gap < 10
 - if OG > 10, consider: methanol poisoning, ethylene glycol poisoning, or another cause of acidosis plus ethanol ingestion

Causes of Increased Osmolar Gap

- Methanol
- Ethylene glycol
- Ethanol
- Polyethylene glycol
- Mannitol
- Sorbitol

Useful Equations

- $AG = [Na^+] - [Cl^-] - [HCO_3^-]$ (normal range = 10-14 mEq/L)
- Osmolar Gap = measured serum osmolality – calculated osmolality (normal < 10 mEq/L)
 - “Two Salts and a Sticky BUN”
- Calculated Osmolality = $2[Na^+] + [Urea] + [Glucose] (+ 1.25[Ethanol])$

Causes of Increased AG Metabolic Acidosis

MUDPILES CAT

- Methanol
- Uremia
- Diabetic ketoacidosis
- Paraldehyde
- Isopropyl alcohol/Iron/Ibuprofen/Indomethacin
- Lactic acidosis
- Ethylene glycol
- Saicylates
- Cyanide and Carbon monoxide
- Alcoholic ketoacidosis
- Toluene

Metabolic Acidosis

Etiology and Pathophysiology

1. Increased AG Metabolic Acidosis (4 types)

1. lactic acidosis (2 types)

- L-lactic acid
 - type A: due to tissue hypoperfusion (any cause of shock), ischemic bowel, profound hypoxemia
 - type B: non-hypoxic – multiple causes; the most common is failure to metabolize normally produced lactic acid in the liver due to severe liver disease; other causes include: excessive alcohol intake, thiamine deficiency, metformin accumulation (metformin interferes with electron transport chain), certain anti-retrovirals, large tumours, mitochondrial myopathies
- D-lactic acid: rare syndrome characterized by episodes of encephalopathy and metabolic acidosis
 - occurs in the setting of carbohydrate malabsorption (e.g. short bowel syndrome), colonic bacteria metabolize carbohydrate load into D-lactic acid, diminished colonic motility and impaired D-lactate metabolism

2. ketoacidosis

- diabetic
- starvation
- alcoholic (decreased carbohydrate intake and vomiting)

3. toxins

- methanol (toxic to brain and retina, can cause blindness and brain death): metabolized to formic acid
 - ethylene glycol (toxic to brain and kidneys): metabolized to oxalic acid (envelope shaped crystals in urine) and multiple other acids
 - salicylate (e.g. ASA) overdose: causes acidosis due to salicylic acid, and also accumulation of lactic acid (salicylate at toxic levels impairs electron transport chain) and ketoacid (salicylate activates fat breakdown)
4. advanced renal failure (e.g. serum Cr increased at least 5x above baseline – a very low GFR causes anion retention, and renal disease leads to impaired bicarbonate production)

2. Normal AG Metabolic Acidosis (Hyperchloremic Acidosis)

- diarrhea (HCO_3^- loss from GI tract)
- RTA
 - type I RTA (distal): inability to secrete H^+ in collecting duct, leading to impaired excretion of ammonium into urine
 - type II RTA (proximal): impaired HCO_3^- reabsorption
 - type III RTA: combination of Types I and II and is extremely rare
 - type IV RTA: defective ammoniogenesis due to decreased aldosterone, hyporesponsiveness to aldosterone, or hyperkalemia
- to help distinguish renal causes from non-renal causes, use Urine AG = $(\text{Na}^+ + \text{K}^+) - \text{Cl}^-$
- calculation establishes the presence or absence of unmeasured positive ions (e.g. NH_4^+) in urine
 - if UAG < 0, suggests adequate NH_4^+ excretion in urine (likely nonrenal cause: diarrhea)
 - if UAG > 0, suggests problem is lack of NH_4^+ in urine (e.g. distal RTA)

Treatment of Metabolic Acidosis

1. treat underlying cause:
 - fluid resuscitation and insulin for DKA
 - restore tissue perfusion for Type A lactic acidosis
 - ethanol/fomepizole \pm dialysis for methanol or ethylene glycol poisoning
 - alkaline diuresis \pm dialysis if ASA overdose
2. correct coexisting disorders of K^+ (see *Hyperkalemia*, NP13)
3. consider treatment with exogenous alkali (e.g. NaHCO_3) if:
 - severe reduction in $[\text{HCO}_3^-]$ e.g. < 8 mmol/L, especially with very low pH (< 7)
 - no metabolizable anion (e.g. salicylate, formate, oxalate, or sulphate); note that lactate and ketoacid anions can be metabolized to HCO_3^-
- note: risks of sodium bicarbonate therapy
 - hypokalemia: causes K^+ to shift into cells (correct K^+ deficit first)
 - ECF volume overload: Na^+ load given with NaHCO_3 , can exacerbate pulmonary edema
 - overshoot alkalosis: abrupt, poorly tolerated transition from overly aggressive alkali loading, partial conversion of accumulated organic anions to HCO_3^- , and persisting hyperventilation

Causes of Non-AG Metabolic Acidosis

HARDUP

Hyperalbuminemia

Acetazolamide

RTA*

Diarrhea*

Ureteroenteric fistula

Pancreaticoduodenal fistula

*Most common

3 Clinical Scenarios that Produce a Mixed Disorder with Near Normal pH

(e.g. increased AG metabolic acidosis + respiratory alkalosis)

- Cirrhosis
- ASA overdose
- Sepsis

Metabolic Alkalosis

Pathophysiology

- requires initiating event and maintenance factors
- precipitating factors
 - GI (vomiting, NG tube) or renal loss of H^+
 - exogenous alkali (oral or parenteral administration), milk alkali syndrome
 - diuretics (contraction alkalosis): decreased excretion of HCO_3^- , decreased ECF volume, therefore increased $[\text{HCO}_3^-]$
 - post-hypercapnia: renal compensation for respiratory acidosis is HCO_3^- retention, rapid correction of respiratory disorder results in transient excess of HCO_3^-
- maintenance factors
 - volume depletion: reduced GFR and increase proximal reabsorption of NaHCO_3^- and increased aldosterone
 - hyperaldosteronism (1° or 2°): distal Na^+ reabsorption in exchange for K^+ and H^+ excretion leads to HCO_3^- generation; aldosterone also promotes hypokalemia
 - hypokalemia: transcellular K^+/H^+ exchange, stimulus for ammoniogenesis and HCO_3^- generation

Evaluate Compensation (identify co-existing respiratory acid-base disorders)

- hypoventilation (an upper limit to compensation exists – breathing cannot be stopped)

Treatment

- treat underlying cause
- correct underlying disease, replenish K^+ and Mg^{2+} deficits, and possibly K^+ -sparing diuretic
- saline sensitive metabolic alkalosis (most common)
 - volume repletion \pm carbonic anhydrase inhibitor (e.g. acetazolamide) to facilitate loss of HCO_3^- in urine
- saline resistant metabolic alkalosis
 - remove source of aldosterone or glucocorticoid \pm spironolactone

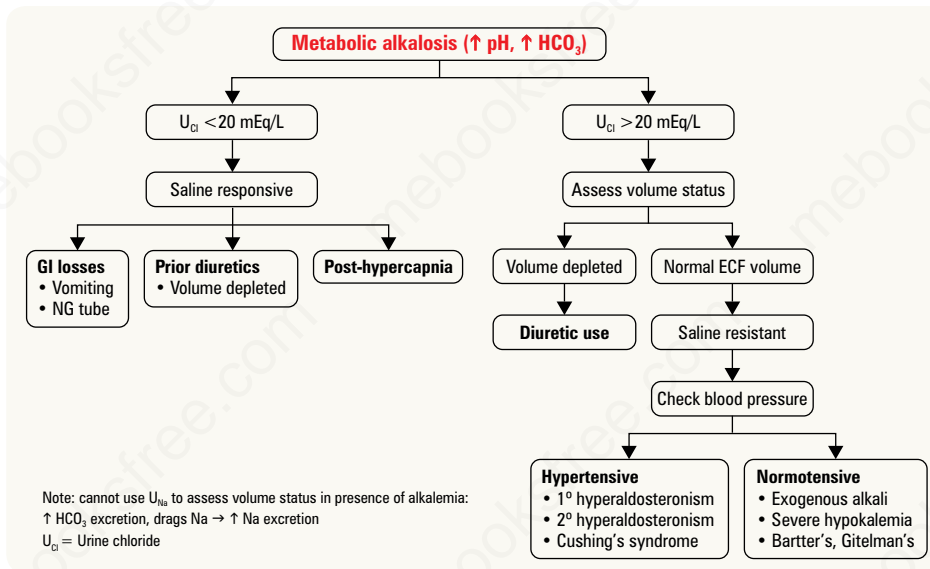

Figure 10. Approach to metabolic alkalosis

Acute Kidney Injury

Definition

- abrupt decline in renal function leading to increased nitrogenous waste products normally excreted by the kidney
- formerly known as acute renal failure

Clinical Presentation

- azotemia (increased BUN, Cr)
- abnormal urine volume: formally $<0.5 \text{ ml/kg/h}$ for $>6 \text{ h}$ but can manifest as anuria, oliguria, or polyuria

Approach to AKI

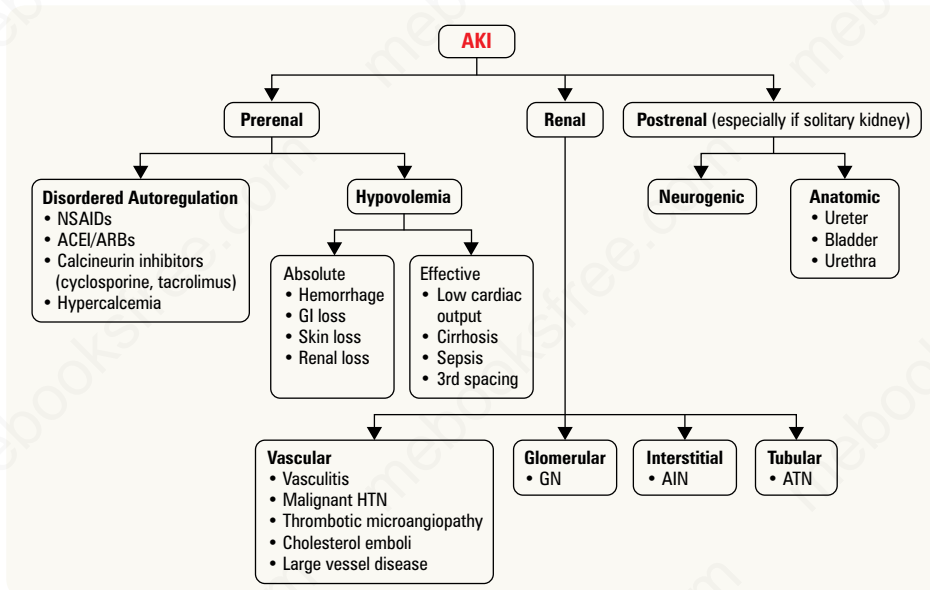

Figure 11. Approach to AKI

Investigations

- blood work: CBC, electrolytes, Cr, urea (think prerenal if increase in urea is relatively greater than increase in Cr), Ca^{2+} , PO_4^{3-}
- urine dipstick: albumin, hemoglobin, WBC's, others: glucose, pH, urobilinogen, specific gravity
- urine volume, C&S, R&M: sediment, casts, crystals
- urinary indices: electrolytes, osmolality
- Foley catheterization (rule out bladder outlet obstruction)

The 2 most common causes of acute kidney injury in hospitalized patients are prerenal azotemia and ATN; remember that prerenal failure can lead to ATN

Clues to Prerenal Etiology

- Clinical: Decreased BP, increased HR, and orthostatic HR and BP changes
- Increased [urea] \gg Increased [Cr]
- Urine $[\text{Na}^+] < 10\text{-}20 \text{ mmol/L}$
- Urine osmolality $>500 \text{ mOsm/kg}$
- Fractional excretion of $\text{Na}^+ < 1\%$

Clues to Renal Etiology

- Appropriate clinical context
- Urinalysis positive for casts: Pigmented granular – ATN, WBC – AIN, RBC – GN
- Systemic features, anemia, thrombocytopenia, HTN, mild-moderate ECF volume overload

Clues to Postrenal Etiology

- Known solitary kidney
- Older man
- Recent retroperitoneal surgery
- Anuria
- Palpable bladder
- Ultrasound shows hydronephrosis

Differentiating Prerenal from ATN

	Prerenal	ATN
Urinalysis	Normal	RBC, pigmented granular casts
Urine $[\text{Na}^+]$	<20	$>20 \text{ mEq/L}$
Urine $[\text{Na}^+]/[\text{Cr}]$	<20	>20
Urine osmolality	>500	$<350 \text{ mOsm/kgH}_2\text{O}$
FeNa	$<1\%$	$>1\%$

- fluid challenge (e.g. fluid bolus to rule out most prerenal causes)
- imaging: abdomen U/S (assess kidney size, hydronephrosis, postrenal obstruction)
- indications for renal biopsy
 - diagnosis is not certain
 - prerenal azotemia or ATN is unlikely
 - oliguria persists > 2-4 days

Treatment

1. preliminary measures

- prerenal
 - ◆ correct prerenal factors: optimize volume status and cardiac performance using fluids that will stay in the plasma subcompartment (NS, albumin, blood/plasma), hold ACEI/ARB (gently rehydrate when needed, e.g. CHF) and NSAIDs
- renal
 - ◆ address reversible renal causes: discontinue nephrotoxic drugs, treat infection, and optimize electrolytes
 - ◆ correct ECF volume, supportive care, consider corticosteroid or immunosuppressive therapy
- postrenal
 - ◆ consider obstruction: structural (stones, strictures) vs. functional (neuropathy)
 - ◆ for obstruction to cause AKI, must have functional solitary kidney or obstruction affecting both kidneys
 - ◆ treat with Foley catheter insertion, indwelling bladder catheter, nephrostomy, stenting

2. treat complications

- fluid overload
 - ◆ NaCl restriction
 - ◆ high dose loop diuretics
 - ◆ hyperkalemia (*see Approach to Hyperkalemia, NP13*)
 - ◆ adjust dosages of medications cleared by kidney (e.g. amiodarone, digoxin, cyclosporin, tacrolimus, some antibiotics, and chemotherapeutic agents)
- dialysis

3. definitive therapy depends on etiology

Prognosis

- high morbidity and mortality in patients with sustained AKI and multi-organ failure

Avoid NSAIDs in patients with diarrhea, heart failure or renal failure

Renal transplant is not a therapy for AKI

Drugs Implicated in Prerenal Azotemia

- Diuretics
- NSAIDs
- ACEI/ARBs

Parenchymal Kidney Diseases

Glomerular Diseases

HISTOLOGICAL TERMS OF GLOMERULAR CHANGES

Extent of Changes

- histological term describing the number of glomeruli affected in a given condition:
 - diffuse: majority of glomeruli abnormal
 - focal: some glomeruli affected
- histological term describing the extent to which individual glomeruli are affected in a given condition
 - global: entire glomerulus abnormal
 - segmental: only part of the glomerulus abnormal

Types of Changes

- proliferation: hyperplasia of one of the glomerular cell types (mesangial, endothelial, parietal epithelial), with or without inflammatory cell infiltration
 - crescent formation: parietal epithelial cell proliferation and mononuclear cell infiltration form crescent-shape in Bowman's space
- membranous changes: capillary wall thickening due to immune deposits or alterations in basement membrane

CLINICAL PRESENTATION OF GLOMERULAR DISEASE

Important Points to Remember

- glomerular diseases have diverse clinical presentations including hematuria, proteinuria, HTN, edema, and decreased GFR
 - each glomerulopathy presents as one of four major glomerular syndromes (these are NOT diagnoses)
 1. asymptomatic urinary abnormalities
 - proteinuria
 - hematuria
 2. nephritic syndrome
 - acute GN
 - rapidly progressive GN
 3. nephrotic syndrome
 4. ESRD

- glomerulopathies can be caused by a primary disease or can occur secondary to a systemic disease
- some glomerulopathies can present as more than one syndrome at different times

The Nephritic-Nephrotic Spectrum

- glomerular pathology can present with a clinical picture anywhere on a spectrum with pure nephritic and pure nephrotic syndromes at the extremes

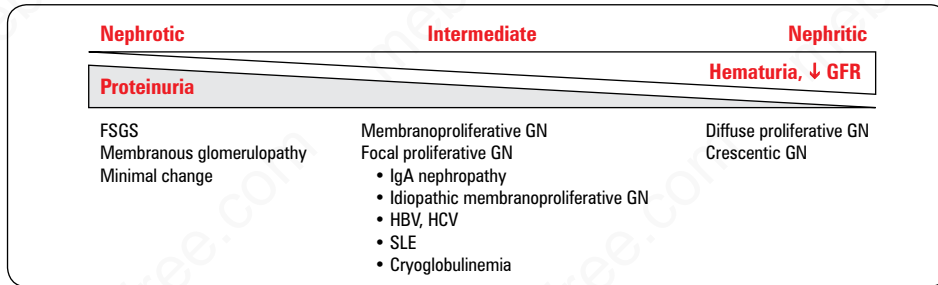

Figure 12. Spectrum of glomerular pathology

PROTEINURIA

- hallmark of nephrotic syndromes
- composition of normal urine protein: albumin, lower molecular proteins (such as immunoglobulin light chain) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)
- 24 h urine protein: gold standard to assess degree of proteinuria
- urine ACR: used to screen for diabetic nephropathy
- microalbuminuria: ACR ≥ 2.0 mg/mmol
 - marker of vascular endothelial function
 - an important prognostic marker for kidney disease in DM and HTN (see *Diabetes*, NP31)
 - microalbuminuria is the earliest sign of diabetic nephropathy
- composition of normal total urine protein
- upper limit of normal daily excretion of total protein is 150 mg/d
- upper limit of normal daily excretion of albumin is 30 mg/d
- the other normally excreted proteins are either filtered low molecular weight proteins (such as immunoglobulin light chains or β -2 microglobulin) or proteins secreted by the tubular epithelial cells (e.g. Tamm-Horsfall mucoprotein)

Pathologic Proteinuria

- Tubulointerstitial**
 - Normally low molecular weight proteins (<60 kDa) pass through glomerular filtration barrier and are reabsorbed in proximal tubule
 - Proximal tubule dysfunction causes impaired reabsorption and increased excretion of low molecular weight proteins
 - Albumin (>60 kDa) is not affected; thus, edema is partly secondary to salt and water retention
- Glomerular**
 - Normally, the filtration barrier is selectively permeable to size (<60 kDa) and charge (repels negative particles); thus, albumin is filtered to a very limited extent through a normal glomerulus
 - Damage to any component of the glomerular filtration barrier results in loss of albumin and other high molecular weight proteins; thus, edema is secondary to hypoalbuminemia (low oncotic pressure), but also due to enhanced renal tubular reabsorption of filtered sodium and water (possibly due to filtered proteins stimulating the action of cortical collecting duct epithelial sodium channel)
- Overflow**
 - Increased production of low molecular weight proteins which exceeds the reabsorptive capacity of the proximal tubule
 - Plasma cell dyscrasias: produce light chain Ig (multiple myeloma, Waldenstrom's macroglobulinemia, monoclonal gammopathy of undetermined significance)

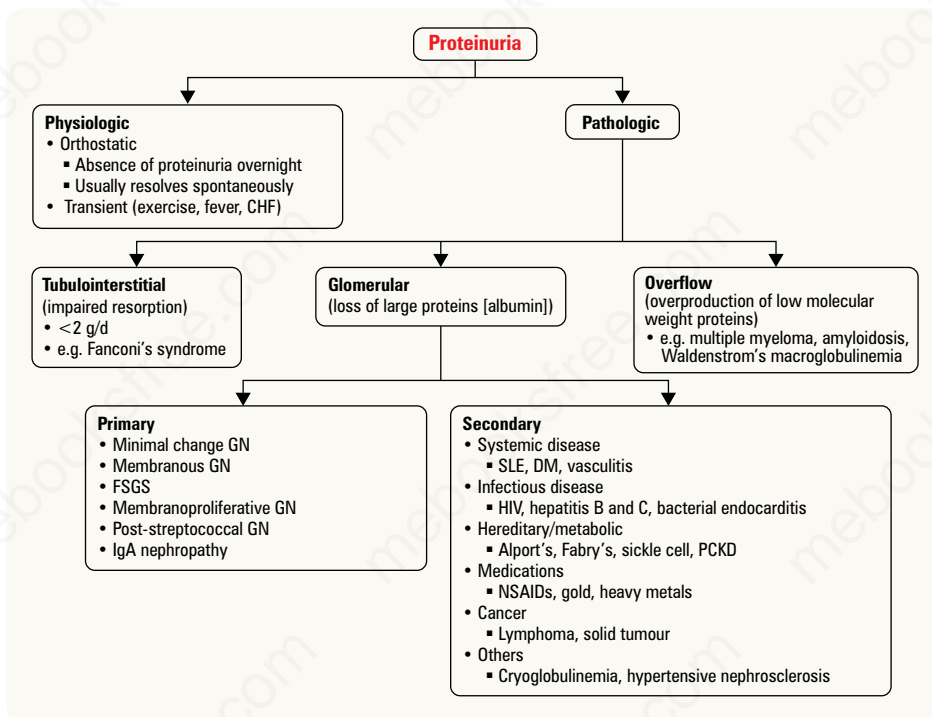

Figure 13. Classification of proteinuria

Table 10. Daily Excretion of Protein

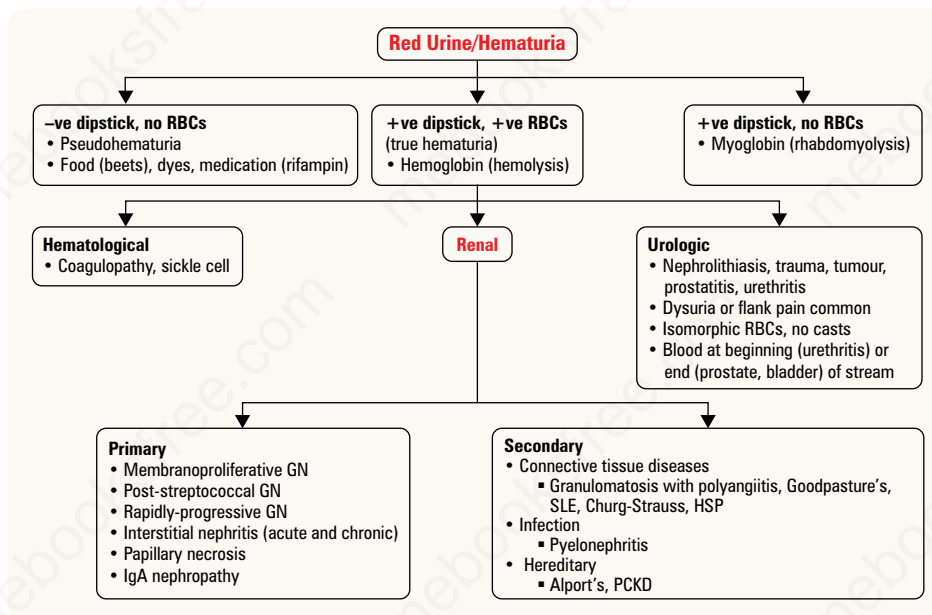

Daily Excretion	Stage of Nephropathy	ACR
<150 mg total protein (and <30 mg albumin)	Normal	Less than 2.0 mg/mmol
30-300 mg albumin	Microalbuminuria	Greater than 2.0 mg/mmol
>3500 mg total protein/1.73m ² BSA	Nephrotic range proteinuria	
Variable amount of proteinuria	Can be seen with glomerular disease	
Up to 2000 mg per d	Possible tubular disease because of failure to reabsorb filtered proteins	

Investigations

- urine R&M, C&S, urea, Cr
- further workup (if degree of proteinuria >0.5 g/d, casts, and/or hematuria)
 - CBC, glucose, electrolytes, 24 h urine protein, and Cr
 - urine and serum immunoelectrophoresis, abdominal/pelvic U/S
 - serology: ANA, RF, p-ANCA (MPO), c-ANCA (PR3), Hep B, Hep C, HIV, ASOT
- indications for nephrology referral
 - generally, if there is “heavy” proteinuria (ACR >30 mg/mmol), should refer to nephrologist
 - definitely if there is nephrotic syndrome: marked proteinuria >3.5 g/1.73m²/d with hypoalbuminemia (<35 g/L)

HEMATURIA

- hallmark of nephritic syndromes
- presence of blood or RBCs in urine
 - gross hematuria: pink, red, or tea-coloured urine
 - ♦ in gross hematuria, the urine should be centrifuged
 - if the sediment is red, true hematuria
 - if the supernatant is red, test for heme with a dipstick
 - if supernatant positive for heme: myoglobinuria or hemoglobinuria
 - if negative for heme: pseudohematuria; consider medications (e.g. rifampin), food dyes (e.g. beets), or metabolites (e.g. porphyria)
 - microscopic hematuria: blood in the urine that is invisible to the naked eye, >2-3 RBCs/HPF on microscopy

**Figure 14. Approach to red urine****Investigations for Hematuria**

- Hx and P/E: family history of nephrolithiasis, hearing loss (Alport Syndrome), cerebral aneurysm (PCKD), diet, recent URTI, irritative and obstructive urinary symptoms (UTI)
- urine R&M, C&S, urea, Cr
- renal U/S
- 24 h urine stone workup if there is a history of stone formation or if there is a stone noted on imaging: calcium, oxalate, citrate, magnesium, uric acid, cysteine
- further workup (if casts and/or proteinuria): CBC, electrolytes, 24 h urine protein and Cr, serology (ANA, RF, C3, C4, p-ANCA, c-ANCA, ASOT)
- consider urology consult and possible cystoscopy if not clearly a nephrologic source for hematuria or if >50 yr of age

Glomerular Syndromes

1. ASYMPTOMATIC URINARY ABNORMALITIES

Clinical/Lab Features

- often have rapid decline in GFR, anemia, elevated inflammatory markers, ECF volume replete or mildly overloaded
- proteinuria (usually <2 g/d) and/or microscopic or macroscopic hematuria
 - isolated proteinuria
 - ♦ can be postural
 - ♦ occasionally can signal beginning of more serious GN (e.g. FSGS, IgA nephropathy, amyloid, diabetic nephropathy)
 - hematuria with or without proteinuria
 - ♦ IgA nephropathy (Berger's disease): most common type of primary glomerular disease worldwide, usually presents after viral URTI
 - ♦ hereditary nephritis (Alport Syndrome – Type IV collagen mutation): X-linked nephritis often associated with sensorineural hearing loss; proteinuria <2 g/d
 - ♦ thin basement membrane disease: usually autosomal dominant, without proteinuria; benign
 - ♦ benign recurrent hematuria: hematuria associated with febrile illness, exercise, or immunization; a diagnosis of exclusion after other possibilities are ruled out

2. NEPHRITIC SYNDROME

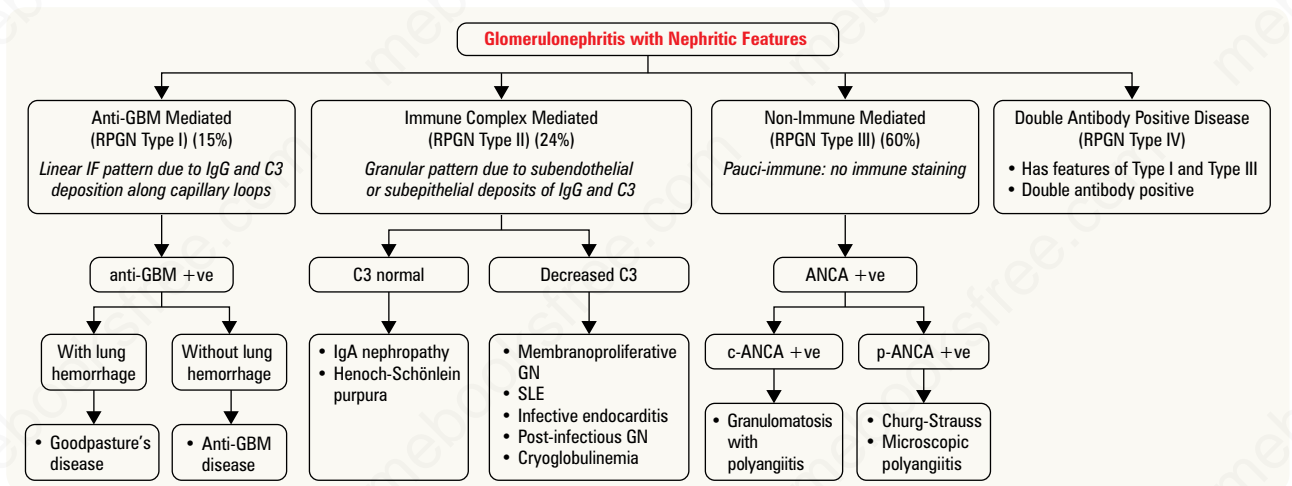

Figure 15. Approach to nephritic syndrome

ACUTE NEPHRITIC SYNDROME

- a subset of nephritic syndrome in which the clinical course proceeds over days
- etiology can be divided into low and normal complement levels
- frequently immune-mediated, with Ig and C3 deposits found in GBM

Clinical/Lab Features

- proteinuria (but <3.5 g/1.73 m²/d)
- abrupt onset hematuria (microscopic or macroscopic)
- azotemia (increased Cr and urea)
- RBC casts and/or dysmorphic RBCs in urine
- oliguria, HTN (due to salt and water retention)
- peripheral edema/puffy eyes
- smoky urine

Treatment

- depends on etiology
- pulse steroid therapy and other immunosuppression, BP control, monitoring for progression to end stage renal disease

RAPIDLY PROGRESSIVE GLOMERULONEPHRITIS

- a subset of nephritic syndrome in which the clinical course proceeds over weeks to months
- clinical diagnosis, not histopathological
- any cause of GN can present as RPGN (except minimal change disease)
- additional etiologies seen only as RPGN: anti-GBM Disease and granulomatosis with polyangiitis (previously called Wegener's granulomatosis)
- crescentic GN (identified by pathology) results from proliferation of parietal epithelial cells and is the most aggressive form of glomerular disease

Clinical/Lab Features

- fibrous crescents typically present on renal histopathology
- RBC casts and/or dysmorphic RBCs in urine
- classified by immunofluorescence staining
- Type I: Anti-GBM mediated (15% of cases)
- Type II: Immune Complex Mediated (24% of cases)
- Type III: Non-Immune Mediated (60% of cases)
- Type IV: Double Antibody Positive

Treatment and Prognosis

- treatment: underlying cause for postinfectious; corticosteroids + cyclophosphamide or other cytotoxic agent + plasmapheresis in management of cases such as Anti-GBM Ab
- prognosis: 50% recovery with early treatment, depends on underlying cause

3. NEPHROTIC SYNDROME**Clinical/Lab Features**

- heavy proteinuria (>3.5 g/1.73 m²/d)
- hypoalbuminemia
- edema
- hyperlipidemia (elevated LDL cholesterol), lipiduria (fatty casts and oval fat bodies on microscopy)
- hypercoagulable state (due to antithrombin III, Protein C, and Protein S urinary losses)
- patient may report frothy urine
- glomerular pathology on renal biopsy
 - minimal change disease (or minimal lesion disease or nil disease) – e.g. glomeruli appear normal on light microscopy
 - membranous glomerulopathy
 - focal segmental glomerulosclerosis (FSGS)
 - membranoproliferative GN
 - nodular glomerulosclerosis
- each can be idiopathic or secondary to a systemic disease or drug (sirolimus can cause proteinuria without obvious glomerular pathology)

Table 11. Nephrotic Syndrome

	Minimal Change	Membranous Glomerulopathy	Focal Segmental Glomerulosclerosis	Membranoproliferative Glomerulonephritis	Nodular Glomerulosclerosis
Secondary Causes	Hodgkin's lymphoma	HBV, SLE, solid tumours (lung, breast, GI)	Reflux nephropathy, HIV, HBV, obesity, sickle cell disease	HCV, malaria, SLE, leukemia, lymphoma, shunt nephritis	DM, amyloidosis
Drug Causes	NSAIDs	Gold, penicillamine	Heroin		
Therapy	Steroids	Reduce BP, ACEI, steroids	Steroids, ACEI/ARB for proteinuria	Aspirin [®] , ACEI, dipyridamole (Persantine [®]) – controversial	Treat underlying cause

4. END STAGE RENAL DISEASE

- see *End Stage Renal Disease*, NP36

INVESTIGATIONS FOR GLOMERULAR DISEASE

- blood work
 - first presentation: electrolytes, Cr, urea, albumin, fasting lipids
 - determining etiology: CBC, ESR, serum immunoelectrophoresis, anti-GBM Disease, C3, C4, ANA, p-ANCA, c-ANCA, cryoglobulins, HBV and HCV serology, ASOT (anti-streptolysin titres), VDRL, HIV
- urinalysis: RBCs, WBCs, casts, protein
- 24 h urine for protein and CrCl
- radiology
 - CXR (infiltrates, CHF, pleural effusion)
 - renal U/S
- renal biopsy (percutaneous or open) if heavy proteinuria or renal insufficiency and cause is not obviously diabetic nephropathy
- urine immunoelectrophoresis
 - for Bence-Jones protein if proteinuria present

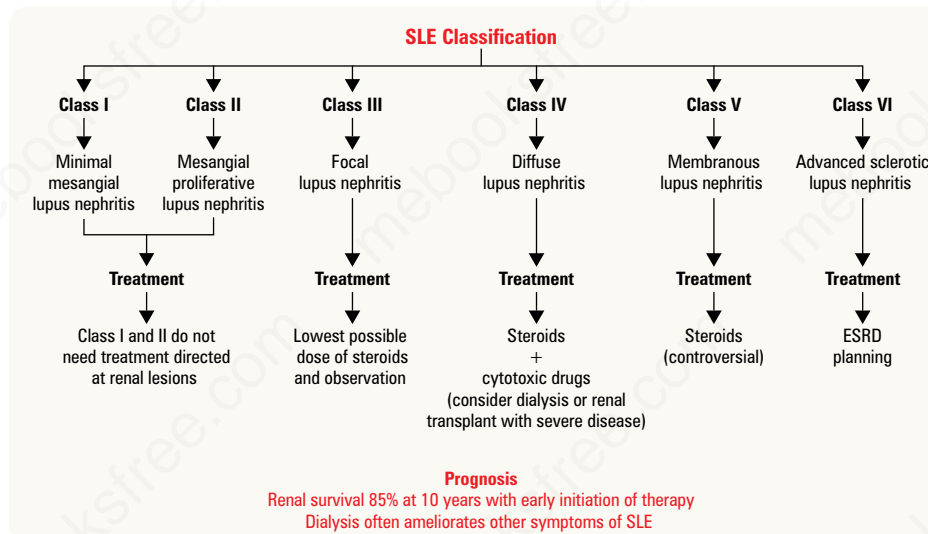

SECONDARY CAUSES OF GLOMERULAR DISEASE

Amyloidosis

- nodular deposits of amyloid in mesangium, usually related to amyloid light chain (AL)
- presents as nephrotic range proteinuria with progressive renal insufficiency
- can be primary or secondary
- secondary causes: multiple myeloma, TB, rheumatoid arthritis, malignancy

Systemic Lupus Erythematosus (see [Rheumatology, RH11](#))

- lupus nephritis can present as any of the glomerular syndromes
- nephrotic syndrome with an active sediment is most common presentation
- GN caused by immune complex deposition in capillary loops and mesangium with resulting renal injury
- serum complement, ANA, anti-DNA levels are usually low during periods of active renal disease
- children and males with SLE are more likely to develop nephritis

EULAR Recommendations for the Management of Systemic Lupus Erythematosus (SLE)

Ann Rheum Dis 2008;67:195-205

Lupus Nephritis Recommendations

Monitoring: Renal biopsy, urine sediment analysis, proteinuria, and kidney function may have independent predictive ability for clinical outcome in therapy of lupus nephritis but need to be interpreted in conjunction. Changes in immunological tests (anti-dsDNA, serum C3) have limited ability to predict response to treatment and may be used only as supplemental information.

Treatment: In patients with proliferative lupus nephritis, glucocorticoids in combination with immunosuppressive agents are effective against progression to end-stage renal disease. Long-term efficacy has been demonstrated only for cyclophosphamide-based regimens, which are associated with considerable adverse effects. In short- and medium-term trials, mycophenolate mofetil has demonstrated at least similar efficacy compared with pulse cyclophosphamide and a more favourable toxicity profile. Failure to respond by 6 mo should evoke discussions for intensification of therapy. Flares following remission are not uncommon and require diligent follow-up.

End-Stage Renal Disease: Dialysis and transplantation in SLE have long-term patient and graft-survival rates comparable with those observed in non-diabetic non-SLE patients, with transplantation being the method of choice.

Figure 16. International Society of Nephrology/Renal Pathology Society classification of lupus nephritis 2003

Henoch-Schönlein Purpura

- seen more commonly in children
- purpura on buttocks and legs, abdominal pain, arthralgia, and fever
- IgA and C3 staining of mesangium
- usually benign, self-limiting course, 10% progress to CKD

Anti-GBM Disease

- Goodpasture Syndrome when lung and renal both involved
- antibodies against type IV collagen present in lungs and GBM
- present with RPGN type I and hemoptysis/dyspnea
- pulmonary hemorrhage more common in smokers and males
- treat with plasma exchange, cyclophosphamide, prednisone

ANCA-Associated Vasculitis

- c-ANCA most commonly associated with the clinical picture of granulomatosis with polyangiitis
- p-ANCA most commonly associated with the clinical picture of microscopic polyangiitis
- focal segmental necrotizing RPGN with no immune staining
- may be indolent or fulminant in progression
- vasculitis and granulomas rarely seen on renal biopsy
- treatment typically involves cyclophosphamide and prednisone

Cryoglobulinemia

- cryoglobulins: monoclonal IgM and polyclonal IgG which precipitate at reduced temperatures
- presents as purpura, fever, Raynaud's phenomenon, and arthralgias
- at least 50% of patients have hepatitis C
- renal disease seen in 40% of patients (isolated proteinuria/hematuria progressing to nephritic syndrome)
- most patients have decreased serum complement (C4 initially)
- treat hepatitis C, plasmapheresis
- overall prognosis: 75% renal recovery

Shunt Nephritis

- immune-complex mediated nephritis associated with chronically infected ventriculoatrial shunts inserted for treatment of hydrocephalus
- presents as acute nephritic syndrome with decreased serum complement
- nephrotic range proteinuria in 25% of patients
- treat by removing shunt and administering appropriate antibiotics

HIV-Associated Renal Disease

1. direct nephrotoxic effect of HIV infection, anti-retroviral drugs (e.g. tenofovir, indinavir), and other drugs used to treat HIV-associated infections
2. HIV-associated nephropathy
 - histology: focal and segmental glomerular collapse with mesangial sclerosis; “collapsing FSGS”
 - tubular cystic dilation and tubulo-reticular inclusions
 - clinical features: predominant in African American men, heavy proteinuria, progressive renal insufficiency (apo-l-1 risk genotypes)
 - prognosis: kidney failure within 1 yr without treatment
 - therapy: short-term, high dose steroids, ACEI, HAART

Infective Endocarditis

- manifests as mild form of acute nephritic syndrome with decreased serum complement
- *S. aureus* is most common infecting agent
- treatment with appropriate antibiotics usually resolves GN

Hepatitis B

- can result in membranous nephropathy, polyarteritis nodosa, membranoproliferative GN

Hepatitis C

- can result in membranous nephropathy, cryoglobulinemia, and membranoproliferative GN

Syphilis

- can result in membranous GN

Tubulointerstitial Disease

TUBULOINTERSTITIAL NEPHRITIS

Definition

- cellular infiltrates affecting primarily the renal interstitium and tubular cells
- functional tubule defects are disproportionately greater than the decrease in GFR
- classified as acute or chronic

Signs and Symptoms

- manifestation of disease depends on site of tubule affected
1. proximal tubule (e.g. multiple myeloma, heavy metals)
 - Fanconi syndrome: decreased reabsorption in proximal tubule causing glycosuria, aminoaciduria, phosphaturia, hyperuricosuria
 - proximal RTA (decreased bicarbonate absorption): Type II RTA
 2. distal tubule (e.g. amyloidosis, obstruction)
 - distal RTA (Type I RTA), usually hypokalemic
 - Na⁺-wasting nephropathy
 - ± hyperkalemia leading to type IV RTA (where reduced renal bicarbonate production is caused by hyperkalemia)
 3. collecting duct (e.g. sickle cell anemia, analgesics, PCKD)
 - urinary concentrating defect leading to mild nephrogenic DI
 - polyuria

1. ACUTE TUBULOINTERSTITIAL NEPHRITIS

Definition

- rapid (days to weeks) decline in renal function
- 10-20% of all AKI

Etiology

- hypersensitivity
 1. antibiotics: β-lactams, sulfonamides, rifampin, quinolones, cephalosporins, fluoroquinolones
 2. other: NSAIDs, allopurinol, furosemide, thiazides, triamterene, PPIs, acyclovir, phenytoin, cimetidine

IgA nephropathy is the most common type of primary glomerular disease worldwide

Features of Nephritic Syndrome

PHAROH
 Proteinuria
 Hematuria
 Azotemia
 RBC casts
 Oliguria
 HTN

Presentation of Nephrotic Syndrome

HELP
 Hypoalbuminemia
 Edema
 Lipid abnormalities
 Proteinuria

- infections
 - bacterial pyelonephritis, *Streptococcus*, brucellosis, *Legionella*, CMV, EBV, toxoplasmosis, leptospirosis, HIV, *Mycoplasma*
- immune
 - SLE, acute allograft rejection, Sjögren's syndrome, sarcoidosis, mixed essential cryoglobulinemia
- idiopathic

Pathophysiology

- acute inflammatory cell infiltrates into renal interstitium

Clinical Features

- AKI
- if hypersensitivity reaction: may see fever, skin rash, arthralgia, serum sickness-like syndrome (particularly rifampin)
- if pyelonephritis: flank pain and costovertebral angle (CVA) tenderness
- if drug reaction, AKI usually occurs 7- 10 days after exposure
- other signs and symptoms based on underlying etiology
- HTN and edema are uncommon

Findings

- urine
 - mild, non-nephrotic range proteinuria and microscopic hematuria
 - sterile pyuria, WBC casts
 - eosinophils if AIN
- blood work
 - increased Cr and urea
 - eosinophilia if drug reaction
 - normal AG metabolic acidosis (RTA)
 - hypophosphatemia, hyperkalemia, hyponatremia
- gallium scan often shows intense signal due to inflammatory infiltrate
- renal biopsy definitive

Treatment

- treat underlying cause (e.g. stop offending medications, antibiotics if pyelonephritis)
- corticosteroids (may be indicated in allergic or immune disease)

Prognosis

- recovery within 2 wk if underlying insult can be eliminated
- the longer the patient is in renal failure, the less likely they will have a full renal recovery

2. CHRONIC TUBULOINTERSTITIAL NEPHRITIS

Definition

- characterized by slowly progressive renal failure, moderate proteinuria, and signs of abnormal tubule function

Etiology

- persistence or progression of acute TIN
- urinary tract obstruction: most important cause of chronic TIN (tumours, stones, bladder outlet obstruction, vesicoureteral reflux)
- chronic pyelonephritis due to vesicoureteral reflux or UTI with obstruction
- nephrotoxins
 - exogenous
 - ♦ analgesics: NSAIDs (common), acetaminophen
 - ♦ cisplatin, lithium, cyclosporine, tacrolimus
 - ♦ heavy metals (lead, cadmium, copper, lithium, mercury, arsenic)
 - ♦ Chinese herbs (aristolochic acid)
 - endogenous
 - ♦ hypercalcemia, hypokalemia, oxalate, uric acid
- vascular disease: ischemic nephrosclerosis, atheroembolic disease
- malignancies: multiple myeloma, lymphoma
- granulomatous: TB, sarcoidosis, granulomatosis with polyangiitis
- immune: SLE, Sjögren's, cryoglobulinemia, Anti-GBM Disease, amyloidosis, renal graft rejection, vasculitis
- hereditary: cystic diseases of the kidney, sickle cell disease
- others: radiation, Balkan (endemic) nephropathy

Pathophysiology

- fibrosis of interstitium with atrophy of tubules, mononuclear cell inflammation

Signs and Symptoms

- dependent on underlying etiology

Findings

- normal AG metabolic acidosis
- hyperkalemia (out of proportion to degree of renal insufficiency)
- polyuria, nocturia
- partial or complete Fanconi's syndrome
- progressive renal failure with azotemia and uremia
- urine: mild proteinuria, few RBCs and WBCs, no RBC casts
- U/S: shrunken kidneys with irregular contours

Treatment

- stop offending agent or treat underlying disease
- supportive measures: correct metabolic disorders (Ca^{2+} , PO_4^{3-}) and anemia

3. ACUTE TUBULAR NECROSIS

Definition

- abrupt and sustained decline in GFR within minutes to days after ischemic/nephrotoxic insult
- GFR reduced (this serves the purpose of avoiding life-threatening urinary loss of fluid and electrolytes from non-functioning tubules)

Etiology

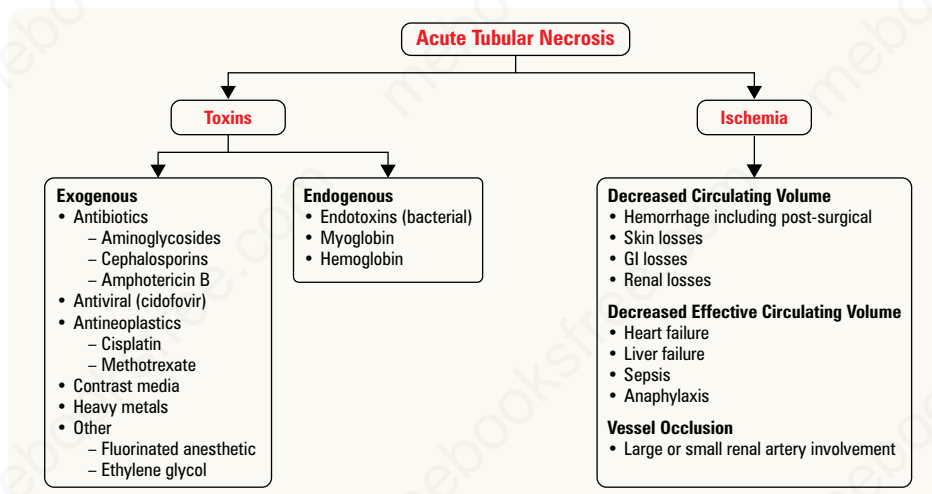

Figure 17. Etiology of ATN

Clinical Presentation

- typically presents as an abrupt rise in urea and Cr after a hypotensive episode, sepsis, rhabdomyolysis, or administration of nephrotoxic drug
- most common cause of non-prerenal AKI in hospitalized patients
- urine: high FE_{Na^+} , pigmented-granular casts

Risk Factors

- pre-existing chronic kidney disease, pre-existing cardiovascular disease, ECF volume depletion, multiple renal insults

Complications

- hyperkalemia: can occur rapidly and cause serious arrhythmias
- metabolic acidosis, decreased Ca^{2+} , increased PO_4^{3-} , hypoalbuminemia

Investigations

- blood work: CBC, electrolytes, Cr, urea, Ca^{2+} , PO_4^{3-} , blood gases
- urine: R&M, electrolytes, osmolality, microscopic urinalysis searching for pigmented granular casts
- ECG
- abdominal U/S
- rule out other causes of prerenal/postrenal azotemia and intrinsic AKI (GN, AIN, vasculitis)

Treatment

- largely supportive once underlying problem is corrected
- loop diuretics may help manage volume overload and reduce tubular metabolic requirements to allow for recovery (controversial)
- consider early dialysis in severe/rapidly progressing cases to prevent uremic syndrome

Meta-Analysis: Effectiveness of Drugs for Preventing Contrast-Induced Nephropathy

Ann Intern Med 2008;148:284-294

Purpose: To determine the effectiveness of N-acetylcysteine, theophylline, fenoldopam, dopamine, iloprost, statin, furosemide, or mannitol on preventing nephropathy.

Study Selection: RCTs that used these agents in patients receiving iodinated contrast.

Results: In the 41 RCTs included N-acetylcysteine ($\text{RR}=0.62$ [0.44-0.88]) and theophylline ($\text{RR}=0.49$ [0.2⁺1.06]) reduced the risk of nephropathy more than saline alone. Furosemide increased the risk ($\text{RR}=3.27$ [1.48-7.26]). Other agents did not affect risk of nephropathy.

Conclusion: N-acetylcysteine is more renoprotective than hydration alone.

Prevention

- correct fluid balance before surgical procedures
- for patients with chronic renal disease requiring radiographic contrast:
 - give N-acetylcysteine 600-1200 mg PO bid day before and day of procedure, give intravenous isotonic fluid (either NaCl or NaHCO₃)
 - isotonic NaHCO₃ at 3 mL/kg over 1 h before procedure and 1 mL/kg/h for 6 h post-procedure if not contraindicated
 - avoid giving diuretics, ACEI, cyclosporine on morning of procedure if possible
- use renal-adjusted doses of nephrotoxic drugs in patients with renal insufficiency

Vascular Diseases of the Kidney

LARGE VESSEL DISEASE

Table 12. Summary of Vascular Diseases

Large Vessel Disease	Medium Vessel Disease	Small Vessel Disease
Acute renal artery occlusion (infarct)	Kawasaki disease	Hypertensive nephrosclerosis
Renal artery stenosis (ischemia)	Polyarteritis nodosa	Atheroembolic renal disease
Renal vein thrombosis		Thrombotic microangiopathy
		Scleroderma
		Calcineurin inhibitor nephropathy
		Hemolytic Uremic Syndrome (HUS)

1. RENAL INFARCTION (ACUTE RENAL ARTERY OCCLUSION)

- important, potentially reversible cause of renal failure

Etiology

- abdominal trauma, surgery, embolism, vasculitis, extra-renal compression, hypercoagulable state, aortic dissection
- kidney transplant recipients more vulnerable

Signs and Symptoms (depend on presence of collateral circulation)

- fever, N/V, flank pain
- leukocytosis, elevated AST, ALP
- marked elevated LDH (LDH >4x upper limit of normal with minimal elevations in AST/ALT strongly suggestive)
- acute onset HTN (activation of RAAS) or sudden worsening of long-standing HTN
- renal dysfunction, e.g. elevated Cr (if bilateral, or solitary functioning kidney)

Investigations

- renal arteriography (more reliable but risk of atheroembolic renal disease)
- contrast-enhanced CT or MR angiography, duplex Doppler studies (operator dependent)

Treatment

- prompt localization of occlusion and restoration of blood flow
- anticoagulation, thrombolysis, percutaneous angioplasty or clot extraction, surgical thrombectomy
- medical therapy in the long-term to reduce risk (e.g. antihypertensives)

2. ISCHEMIC RENAL DISEASE (RENAL ARTERY STENOSIS)

- chronic renal impairment secondary to hemodynamically significant renal artery stenosis or microvascular disease
- significant cause of ESRD: 15% in patients >50 yr (higher prevalence if significant vascular disease)
- usually associated with large vessel disease elsewhere
- causes of renal artery stenosis
 - atherosclerotic plaques (90%): proximal 1/3 renal artery, usually males >55 yr, smokers
 - fibromuscular dysplasia (10%): distal 2/3 renal artery or segmental branches, usually young females (typical onset <30 yr)
- when there is decreased RBF, GFR is dependent on angiotensin II-induced efferent arteriolar constriction which raises the FF (GFR/RBF)
- most common cause of secondary HTN ("renovascular HTN"), 1-2% of all hypertensive patients
 - etiology
 - ♦ decreased renal perfusion of one or both kidneys leads to increased renin release and subsequent angiotensin production
 - ♦ increased angiotensin raises blood pressure in two ways
 1. causes generalized arteriolar constriction
 2. release of aldosterone increases Na⁺ and water retention
 - elevated blood pressure can in turn lead to further damage of kidneys and worsening HTN

Risk Factors

- >50 yr
- smoking
- other atherosclerotic disease (dyslipidemia, DM, diffuse atherosclerosis)

Signs and Symptoms

- severe/refractory HTN and/or hypertensive crises, with negative family history of HTN
- asymmetric renal size
- epigastric or flank bruits
- spontaneous hypokalemia (renin activation in under-perfused kidney)
- increasing Cr with ACEI/ARB
- flash pulmonary edema with normal LV function

Investigations

- must establish presence of renal artery stenosis and prove it is responsible for renal dysfunction
- duplex Doppler U/S (kidney size, blood flow): good screening test (operator dependent)
- digital subtraction angiography (risk of contrast nephropathy)
- CT or MR angiography (effective noninvasive tests to establish presence of stenosis, for MR avoid gadolinium contrast if eGFR <30 mL/min because of risk of systemic dermal fibrosis)
- ACEI renography (e.g. captopril renal scan)
- renal arteriography (gold standard)

Treatment

- surgical: percutaneous angioplasty ± stent, surgical revascularization, occasionally surgical bypass
- medical: BP lowering medications (ACEI is drug of choice if unilateral renal artery disease but contraindicated if bilateral renal artery disease)
- little or no benefit if therapy is late (e.g. kidney is already shrunken), however, therapy can be considered to save the opposite kidney if normal

3. RENAL VEIN THROMBOSIS**Etiology**

- hypercoagulable states (e.g. nephrotic syndrome, especially membranous), ECF volume depletion, extrinsic compression of renal vein, significant trauma, malignancy (e.g. RCC), sickle cell disease
- clinical presentation determined by rapidity of occlusion and formation of collateral circulation

Signs and Symptoms

- acute: N/V, flank pain, hematuria, elevated plasma LDH, ± rise in Cr, sudden rise in proteinuria
- chronic: PE (typical first presenting symptom), increasing proteinuria and/or tubule dysfunction

Investigations

- renal venography (gold standard), CT or MR angiography, duplex Doppler U/S

Treatment

- thrombolytic therapy ± percutaneous thrombectomy for acute renal vein thrombosis
- anticoagulation with heparin then warfarin (1 yr or indefinitely, depending on risk factors)

MEDIUM VESSEL DISEASE**1. KAWASAKI DISEASE**

- see [Pediatrics, P87](#)

2. POLYARTERITIS NODOSA

- see [Rheumatology, RH19](#)
- kidneys most commonly involved organ
- heterogenous impact on renal function
- pathologically can cause glomerular ischemia which manifests as mild proteinuria and hypertension

SMALL VESSEL DISEASE**1. HYPERTENSIVE NEPHROSCLEROSIS**

- see [Hypertension, NP35](#)

2. ATHEROEMBOLIC RENAL DISEASE

- progressive renal insufficiency due to embolic obstruction of small- and medium-sized renal vessels by atheromatous emboli
- spontaneous or after renal artery manipulation (surgery, angiography, percutaneous angioplasty)

**Stenting and Medical Therapy for Atherosclerotic Renal Artery Stenosis**

NEJM 2014;370:13-22

Study: Multicentre, unblinded RCT, median follow-up of 43 mo.

Patients: 947 patients with atherosclerotic renal-artery stenosis who also have significant systolic HTN or CKD.

Intervention: Percutaneous revascularization (stenting) with medical therapy (statins, ARB, calcium channel blockers, HCTZ and BP control) versus medical therapy alone.

Outcomes: Occurrence of adverse CV or renal event (composite of death from CV or renal cause, MI, stroke, hospitalization for CHF, progressive renal insufficiency, or need for renal replacement therapy) and all-cause mortality.

Results: No significant difference in primary composite end point between participants who received stenting or those on medical therapy alone. No significant differences between the treatment groups in the rates of the individual components of the primary end point or in all-cause mortality.

Conclusion: Renal artery stenting did not confer a significant benefit with respect to the prevention of clinical events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal artery stenosis and HTN or CKD.

- anticoagulants and thrombolytics interfere with ulcerated plaque healing and can worsen disease
- investigations
 - eosinophilia, eosinophiluria, and hypocomplementemia
 - renal biopsy: needle-shaped cholesterol clefts (due to tissue-processing artifacts) with surrounding tissue reaction in small-/medium-sized vessels
- treatment
 - no effective treatment; avoid angiographic and surgical procedures in patients with diffuse atherosclerosis, medical therapy for concomitant cardiovascular disease
- prognosis: poor overall, at least one third will develop ESRD

3. THROMBOTIC MICROANGIOPATHY

- see **Hematology, H22**
- etiologies include the spectrum of TTP-HUS, DIC, severe preeclampsia
- renal involvement more common in HUS than TTP
- renal involvement characterized by fibrin thrombi in glomerular capillary loops ± arterioles
- treatment
 - depends on cause
 - supportive therapy
 - TTP-HUS: plasma exchange, corticosteroids (splenectomy and rituximab if refractory)
- avoid platelet transfusions and ASA

4. CALCINEURIN INHIBITOR NEPHROPATHY

- cyclosporine and tacrolimus
- causes both acute reversible and chronic, largely irreversible nephrotoxicity
- major cause of kidney failure in other solid organ transplants (e.g. heart)
- acute: due to afferent and efferent glomerular capillary constriction leading to decreased GFR (tubular vacuolization)
 - prerenal azotemia
 - treatment: calcium channel blockers or prostaglandin analogs, reduce dose of cyclosporine or switch to another immunosuppressive drug
- chronic: result of obliterative arteriopathy causing interstitial nephritis and CKD (striped fibrosis), less frequent now due to lower doses of calcineurin inhibitors

Reduced Exposure to Calcineurin Inhibitors in Renal Transplantation (ELITE-Symphony Trial)

NEJM 2007;257:2562-2575

Study: Multicentre, RCT with 12 mo follow-up.

Patients: 1,645 patients scheduled to receive a single organ kidney transplant.

Intervention: Mycophenolate mofetil, corticosteroids, and either: 1) standard dose cyclosporine; 2) low dose cyclosporine with daclizumab induction; 3) low dose tacrolimus with daclizumab induction; 4) low dose sirolimus with daclizumab induction.

Primary Outcome: Estimated Cockcroft-Gault GFR 12 mo after transplantation.

Results: The tacrolimus arm showed significantly higher eGFR at 12 mo compared to all other arms (65.4 mL/min vs. 57.1, 59.4, 56.7 for arms 1, 2, 4 respectively, $p < 0.001$). The tacrolimus arm also showed decreased rates of acute rejection at 6 mo and 12 mo vs. all arms ($p < 0.001$), improved allograft survival against standard dose cyclosporine and sirolimus, and decreased treatment failure against all other arms. There was no difference in overall patient survival between groups. Sirolimus had the highest incidence of lymphoceles, delayed wound healing, and serious adverse events; tacrolimus had significantly higher rates of new-onset DM; and cyclosporine regimens had the lowest incidence of diarrhea but highest opportunistic infection rates.

Conclusion: Immunosuppression regimens using low dose tacrolimus and daclizumab induction decrease nephrotoxicity while maintaining therapeutic immunosuppression in renal transplant patients.

Analgesic Nephropathies

1. Vasomotor AKI

- clinically: develop prerenal azotemia within a few days of starting NSAID
- normally prostaglandins vasodilate afferent renal arteriole to maintain blood flow
- NSAIDs act by blocking cyclooxygenase enzyme, thereby preventing prostaglandin synthesis and causing renal ischemia
- more common in elderly, underlying renal disease, hypovolemia (diuretics, CHF, cirrhosis, nephrotic syndrome)
- treatment: discontinue NSAID, dialysis rarely needed

2. Acute Interstitial Nephritis

- fenoprofen (60%), ibuprofen, naproxen
- may be associated with minimal change glomerulopathy and nephrotic range proteinuria
- resolves eventually with discontinuation of NSAID, may require interval dialysis
- short-term high dose steroids (1 mg/kg/d of prednisone) may hasten recovery

3. Chronic Interstitial Nephritis

- due to excessive consumption of antipyretics (phenacetin or acetaminophen) in combination with NSAIDs
- seen in patients who also have emotional stress, psychiatric symptoms, and GI disturbance
- papillary necrosis
 - gross hematuria, flank pain, declining renal function
 - calyceal filling defect seen with IVP – “ring sign”
- increased risk of transitional cell carcinoma of renal pelvis
- good prognosis if discontinue analgesics

4. Acute Tubular Necrosis

- can be caused by acetaminophen
 - incidence of renal dysfunction is related to the severity of acetaminophen ingestion
- vascular endothelial damage can also occur
- both direct toxicity and ischemia contribute to the tubular damage
- renal function spontaneously returns to baseline within 1-4 wk
- dialysis may be required during the acute episode of ingestion

5. Other Effects of NSAIDs

- sodium retention (2° to reduced GFR)
- hyperkalemia, HTN (2° to hyporeninemic hypoaldosteronism)
- excess water retention (2° to loss of antagonistic effect of prostaglandins on ADH)

Systemic Disease with Renal Manifestation

Diabetes

- diabetic nephropathy: presence of microalbuminuria or overt nephropathy (e.g. macroalbuminuria) in patients with DM who lack indicators of other renal diseases
- most common cause of end-stage renal failure in North America
- 50% of patients with diabetes will develop nephropathy
- at diagnosis up to 30% of patients with type 2 DM have albuminuria (75% microalbuminuria, 25% overt nephropathy)
- microalbuminuria is a risk factor for progression to overt nephropathy and cardiovascular disease
- once macroalbuminuria is established, renal function declines, 50% of patients reach ESRD within 7-10 yr
- associated with HTN and diabetic retinopathy (especially type 1 DM) and/or neuropathy (especially type 2 DM)
- indication of possible non-diabetic cause of renal disease in patients with DM
 - rising Cr with little/no proteinuria
 - lack of retinopathy or neuropathy (microvascular complications)
 - persistent hematuria (microscopic or macroscopic)
 - signs or symptoms of systemic disease
 - inappropriate time course; rapidly rising Cr, renal disease in a patient with short duration of DM
 - family history of non-diabetic renal disease (e.g. PCKD, Alport's)

DM is one of the causes of ESRD that does not result in small kidneys at presentation of ESRD; the others are amyloidosis, HIV nephropathy, PCKD, and multiple myeloma

Abnormal Urine ACR Values from 2013 Canadian DM Association CPG >2.0 mg/mmol in males and females

ACEI can cause hyperkalemia; therefore, be sure to watch serum K⁺, especially if patient has DM and renal insufficiency

DIABETIC RENAL COMPLICATIONS

1. Progressive Glomerulosclerosis

- classic diabetic glomerular lesion: Kimmelstiel-Wilson nodular glomerulosclerosis (15-20%)
- more common lesion is diffuse glomerulosclerosis with a uniform increase in mesangial matrix

Table 13. Stages of Diabetic Progressive Glomerulosclerosis

Stage 1	Stage 2	Stage 3	Stage 4
↑ GFR (120-150%) – compensatory hyperfiltration	Detectable microalbuminuria (0-300 mg/24 h)	Macroalbuminuria (>300 mg/24 h)	↑ proteinuria (>500 mg/24 h)
± slightly increased mesangial matrix	Albumin-Cr ratio (ACR) 2.0-20 mg/mmol (18-180 mg/d)	ACR >20 mg/mmol, (>180 mg/d)	↓ GFR
	↑ mesangial matrix	Proteinuria (positive urine dipstick)	<20% glomerular filtration surface area present
		Normal GFR	Sclerosed glomeruli
		↑↑↑ mesangial matrix	

Figure 18. GFR and urine protein over time in DM

2. Accelerated Atherosclerosis

- common finding
- decreased GFR
- may increase angiotensin II production resulting in increased BP
- increased risk of ATN secondary to contrast media

3. Autonomic Neuropathy

- affects bladder leading to functional obstruction and urinary retention
- residual urine promotes infection
- obstructive nephropathy

4. Papillary Necrosis

- type 1 DM susceptible to ischemic necrosis of medullary papillae
- sloughed papillae may obstruct ureter
- can present as renal colic or with obstructive features ± hydronephrosis

Protein Restriction for Diabetic Renal Disease
Cochrane DB Syst Rev 2007;4:CD002181
Purpose: To review the effects of dietary protein restriction on the progression of diabetic nephropathy.
Study Selection: RCTs and before and after studies of the effects of restricted protein diet on renal function in subjects with DM. 12 studies were reviewed.
Results: The risk of end-stage renal disease or death was lower in patients on low-protein diet. In patients with type 1 DM no effect on GFR was noted in the low-protein diet group.

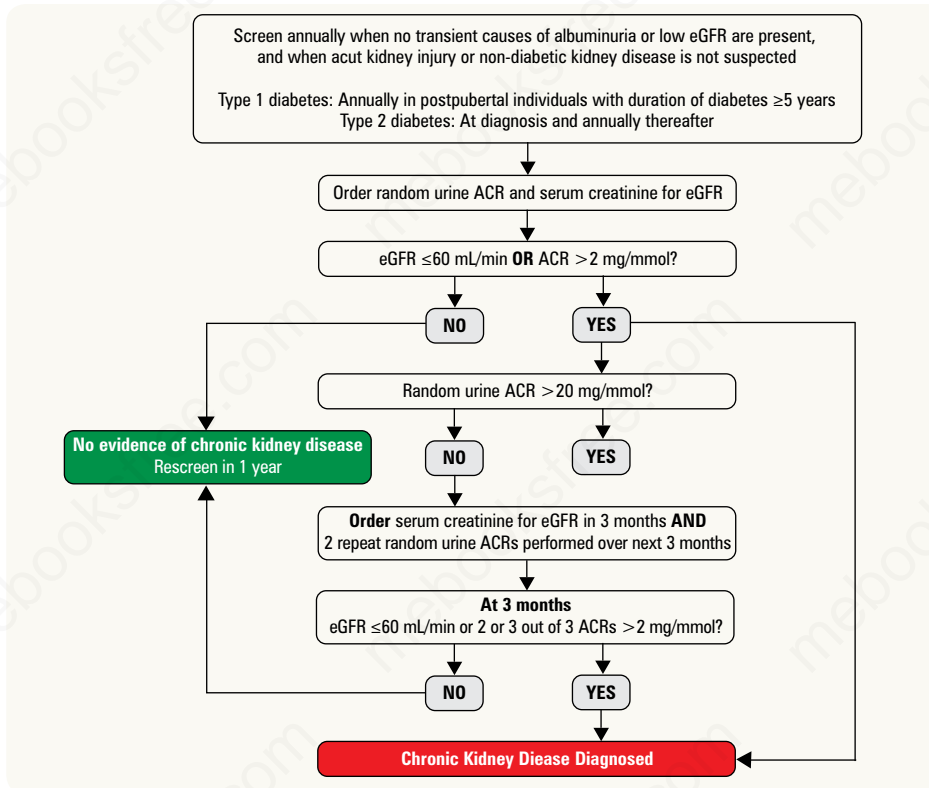

Figure 19. Clinical practice guidelines on chronic kidney disease in diabetes

Canadian Diabetes Association Clinical Practice Guidelines Expert Committee. Canadian Diabetes Association 2013 Clinical Practice Guidelines for the Prevention and Management of Diabetes in Canada. *Can J Diabetes* 2013;37(suppl 1):S1-S212

Priorities in the Management of Patients with DM

- vascular protection for all patients with DM
 - ACEI, antiplatelet therapy (as indicated)
 - BP control, glycemic control, lifestyle modification, lipid control
 - Canagliflozin provides renoprotection independent of its glycemic effects
- optimization of BP in patients who are hypertensive
 - treat according to HTN guidelines
- renal protection for DM patients with nephropathy (even in absence of HTN)
 - type 1 DM: ACEI or ARB
 - type 2 DM: CrCl >60 mL/min: ACEI or ARB – CrCl <60 mL/min: ARB
 - 2nd line agents: nondihydropyridine calcium channel blockers (diltiazem, verapamil)
 - combination of ACEI and ARB not recommended for proteinuria
- check serum Cr and K⁺ levels within 1 wk of initiating ACEI or ARB and at time of acute illness
- serum Cr can safely be allowed to rise up to 30% with initiation of ACEI or ARB, usually stabilizes after 2-4 wk, monitor for significant worsening of renal function or hyperkalemia
- if >30% rise in serum Cr or hyperkalemia, discontinue medication and consider 2nd line agent
- consider holding ACEI, ARB, and/or diuretic with acute illness and in women before becoming pregnant
- consider referral to nephrologist if ACR >60 mg/mmol, eGFR <30 mL/min, progressive kidney function loss, unable to achieve BP targets, or unable to stay on ACEI or ARB

Renal Outcomes with Telmisartan, Ramipril, or Both in People at High Vascular Risk (ONTARGET Study)

Lancet 2008;372:547-553

Study: Prospective, multicentre, double-blind, RCT.

Participants: 25,620 patients with median follow-up of 56 mo.

Intervention: Patients received either ramipril (10 mg/d; n=8,576), telmisartan (80 mg/d; n=8,542), or a combination of both drugs (n=8,502).

Primary Outcome: Composite of dialysis, doubling of creatinine level, and death.

Results: The number of outcome events was similar for telmisartan (n=1,147) and ramipril (1,150; HR 1.00, 95% CI 0.92-1.09), but was increased with combination therapy (1,233; HR 1.09, 1.01-1.18, p=0.037). The need for dialysis or doubling of serum creatinine, was similar with telmisartan (189) and ramipril (174; HR 1.09, 0.89-1.34) and more frequent with combination therapy (212; HR 1.24, 1.01-1.51, p=0.038). Estimated GFR declined least with ramipril compared with telmisartan or combination therapy (p<0.001). The increase in urinary albumin excretion was less with telmisartan (p=0.004) and combination therapy (p=0.001) than with ramipril.

Conclusion: Renal outcomes were similar in both telmisartan and ramipril monotherapy. Combination therapy reduced proteinuria to a greater extent than monotherapy, but was associated with poorer renal outcomes.

Scleroderma

- see [Rheumatology, RH13](#)
- 50% of scleroderma patients have renal involvement (mild proteinuria, high Cr, HTN)
- renal involvement usually occurs early in the course of illness
- histology: media thickened, "onion skin" hypertrophy of small renal arteries, fibrinoid necrosis of afferent arterioles and glomeruli
- 10-15% of scleroderma patients have a "scleroderma renal crisis" (occurs in first few years of disease): malignant HTN, ARF, microangiopathy, volume overload, visual changes, HTN encephalopathy
- treatment: BP control with ACEI slows progression of renal disease

Multiple Myeloma

- see [Hematology, H49](#)
- malignant proliferation of plasma cells in the bone marrow with the production of immunoglobulins
- patients may present with severe bone disease and renal failure
- light chains are filtered at the glomerulus and appear as Bence-Jones proteins in the urine (monoclonal light chains)
- kidney damage can occur by several mechanisms
 - hypercalcemia
 - light chain cast nephropathy or “myeloma kidney”
 - hyperuricemia
 - infection
 - secondary amyloidosis
 - monoclonal Ig deposition disease
 - diffuse tubular obstruction
- light chain cast nephropathy
 - large tubular casts in urine sediment (light chains + Tamm-Horsfall protein)
 - proteinuria and renal insufficiency, can progress rapidly to kidney failure
- monoclonal Ig deposition disease
 - deposits of monoclonal Ig in kidney, liver, heart, and other organs
 - mostly light chains (85-90%)
 - causes nodular glomerulosclerosis (similar to diabetic nephropathy)
- lab features: increased BUN, increased Cr, urine protein immunoelectrophoresis positive for Bence-Jones protein (not detected on urine dipstick)
- poor candidates for kidney transplantation

Malignancy

- cancer can have many different renal manifestations
- kidney transplantation cannot be performed unless malignancy is cured
 - solid tumours: mild proteinuria or membranous GN
 - lymphoma: minimal change GN (Hodgkin's) or membranous GN (non-Hodgkin's)
 - renal cell carcinoma
 - tumour lysis syndrome: hyperuricemia, diffuse tubular obstruction, hyperkalemia, hyperphosphatemia, hypocalcemia, lactic acidosis
 - chemotherapy (especially cisplatin): ATN or chronic TIN
 - pelvic tumours/mets: postrenal failure secondary to obstruction
 - 2° amyloidosis
 - radiotherapy (radiation nephritis)

Chronic Kidney Disease

Definition

- progressive abnormalities of kidney function for >3 months, with either
 - GFR <60 mL/min/1.73 m²; or
 - markers of kidney damage, including
 - albuminuria; or
 - small shrunken kidney <9 cm with increased cortical echogenicity on ultrasound; or
 - pathology on biopsy

Clinical Features

- volume overload and HTN
- electrolyte and acid-base balance disorders (e.g. metabolic acidosis)
- uremia (e.g. nausea/vomiting, pruritus, encephalopathy)
- anemia
- bone mineral disorders

Incidence of Etiologies of CKD

DM	42.9%
HTN	26.4%
Glomerulonephritis	9.9%
Other/Unknown	7.7%
Interstitial nephritis/ Pyelonephritis	4.0%
Cystic/Hereditary/Congenital	3.1%
Secondary GN/Vasculitis	2.4%

Management of Complications of CKD

- NEPHRON**
- N** – Low-nitrogen diet
 - E** – Electrolytes: monitor K⁺
 - P** – pH: metabolic acidosis
 - H** – HTN
 - R** – RBCs: manage anemia with erythropoietin
 - O** – Osteodystrophy: give calcium between meals (to increase Ca²⁺) and calcium with meals (to bind and decrease PO₄³⁻)
 - N** – Nephrotoxins: avoid nephrotoxic drugs (ASA, gentamicin) and adjust doses of renally excreted medications

Table 14. Stages of CKD (KDIGO, 2013)

GFR Categories (mL/min/1.73m ²)	GFR (mL/min/1.73m ²)	Persistent Albuminuria Categories		
		A1 <30 mg/g <3 mg/mmol	A2 30-300 mg/g 3-30 mg/mmol	A3 >300 mg/g >30 mg/mmol
G1	≥90	1 if CKD	1	2
G2	60-89	1 if CKD	1	2
G3a	45-59	1	2	3
G3b	30-44	2	3	3
G4	15-29	3	3	4+
G5	<15 (kidney failure)	4+	4+	4+

The numbers in the boxes are a reflection of the risk of progression and are a guide to the frequency of monitoring/year

"D" is added to G5 for patients requiring dialysis

Classification is based on cause, GFR, and amount of albuminuria

Rate of progression and risk of complications are determined by the cause of CKD

Renin Angiotensin System Blockade and Cardiovascular Outcomes in Patients with Chronic Kidney Disease and Proteinuria: A Meta-Analysis

Am Heart J 2008;155:791-805

Purpose: To evaluate the role of RAS blockade in improving cardiovascular CV outcomes in patients with CKD.

Study Selection: RCT that analyzed CV outcomes in patients with CKD/proteinuria treated with RAS blockade (ACEI/ARB). RAS blockade-based therapy was compared with placebo and control therapy (β-blocker, calcium-channel blockers, and other antihypertensive-based therapy) in the study.

Results: Twenty-five trials (n=45,758) were included. Compared to placebo, RAS blockade reduced the risk of heart failure in patients with diabetic nephropathy. In patients with non-diabetic CKD, RAS blockade decreased CV outcome compared to control therapy.

Conclusions: RAS blockade reduced CV outcomes in diabetic nephropathy as well as non-diabetic CKD.

Effects of Lowering LDL Cholesterol with Simvastatin and Ezetimibe in Patients with Chronic Kidney Disease

Lancet 2011;377:2181-2192

Purpose: To assess the efficacy and safety of the combination of simvastatin and ezetimibe in patients with moderate to severe CKD.

Study: Randomized, double-blind trial with 9,270 patients with CKD with no known history of myocardial infarction or coronary vascularization. Patients were randomized to simvastatin 20 mg plus ezetimibe 10 mg daily versus matching placebo.

Primary Outcome: First major atherosclerotic event (non-fatal myocardial infarction or coronary death, non-hemorrhagic stroke, or any arterial revascularization procedure).

Results: The simvastatin plus ezetimibe group was associated with an average LDL cholesterol difference of 0.85 mmol/L during a median follow-up of 4.9 yr. There was a 17% proportional reduction in major atherosclerotic events in the simvastatin plus ezetimibe group compared to placebo.

Conclusions: Reducing LDL cholesterol with a treatment regimen of simvastatin plus ezetimibe safely reduced the incidence of major atherosclerotic events in patients with moderate to severe CKD.

Management of Chronic Kidney Disease

- diet
 - preventing HTN and volume overload
 - Na⁺ and water restriction
 - preventing electrolyte imbalances
 - K⁺ restriction (40-60 mmol/d)
 - PO₄³⁻ restriction (1 g/d)
 - avoid extra-dietary Mg²⁺ (e.g. antacids)
 - preventing uremia and potentially delaying decline in GFR
 - protein restriction with adequate caloric intake in order to limit endogenous protein catabolism
- medical
 - adjust dosages of renally excreted medications
 - HTN: ACEI (target 140/90 mmHg without DM and 130/80 mmHg with DM), loop diuretics when GFR <25 mL/min
 - dyslipidemia: statins (target LDL <2 mmol/L)
 - calcium and phosphate disorders
 - calcium supplements (e.g. TUMS[®]) treats hypocalcemia when given between meals and binds phosphate when given with meals
 - consider calcitriol (1,25-dihydroxy-vitamin D) if hypocalcemic, but hold if hyperphosphatemic (reduces PTH)
 - sevelamer (phosphate binder) if both hypercalcemic and hyperphosphatemic
 - cinacalcet for hyperparathyroidism (sensitizes parathyroid to Ca²⁺, decreasing PTH)
 - metabolic acidosis: sodium bicarbonate
 - anemia: erythropoietin injections for Hb <90 g/L (9 g/dL) and target Hb between 90-105 g/L (9-10.5 g/dL)
 - clotting abnormalities: DDAVP if patient has clinical bleeding or invasive procedures (acts to reverse platelet dysfunction)
- dialysis (hemodialysis, peritoneal dialysis)
 - indications include persistent and refractory hyperkalemia or metabolic acidosis, fluid overload, encephalopathy, persistent nausea and vomiting, evidence of malnutrition, pericarditis
- renal transplantation for end stage kidney disease

Prevention of Progression

- as above
- control of HTN, DM (HbA1c <7%), cardiovascular risk factors (e.g. smoking cessation, physical activity, weight loss)
- avoid nephrotoxins such as NSAID's, COXIB's, IV contrast in patients with eGFR < 60 mL/min/1.73 m²
- address reversible causes of AKI

Hypertension

- see [Family Medicine, FM34](#)
- HTN occurs in about 20% of population
- etiology classified as primary ("essential"; makes up 90% of cases) or secondary
- primary HTN can cause kidney disease (hypertensive nephrosclerosis), which may in turn exacerbate the HTN
- secondary HTN can be caused by renal parenchymal or renal vascular disease

Hypertensive Nephrosclerosis

Table 15. Chronic vs. Malignant Nephrosclerosis

	Chronic Nephrosclerosis	Malignant Nephrosclerosis
Histology	Slow vascular sclerosis with ischemic changes affecting intralobular and afferent arterioles	Fibrinoid necrosis of arterioles, disruption of vascular endothelium
Clinical Picture	Black race, underlying CKD, chronic hypertensive disease	Acute elevation in BP (DBP > 120 mmHg) HTN encephalopathy
Urinalysis	Mild proteinuria, normal urine sediment	Proteinuria and hematuria (RBC casts)
Therapy	Blood pressure control, (target <140/90) with frequent follow-up	Lower DBP to 100-110 mmHg within 6-24 h More aggressive treatment can cause ischemic event Identify and treat underlying cause of HTN
Prognosis	Can progress to renal failure despite patient adherence	Lower survival if renal insufficiency develops

Renovascular Hypertension

- see [Vascular Diseases of the Kidney, NP28](#)

Renal Parenchymal Hypertension

- HTN secondary to GN, AIN, diabetic nephropathy, or any other chronic renal disease
- mechanism of HTN not fully understood but may include:
 - excess RAAS activation due to inflammation and fibrosis in multiple small intra-renal vessels
 - production of unknown vasopressors, lack of production of unknown vasodilators, or lack of clearance of endogenous vasopressor
 - ineffective sodium excretion with fluid overload

Investigations

- as well as investigations for renovascular HTN, additional tests may include
 - 24 h urinary estimations of CrCl and protein excretion
 - imaging (U/S, CT)
 - serology for collagen-vascular disease
 - renal biopsy (very rarely if at all)

Treatment

- most chronic renal disease is irreversible, but treatment of HTN can slow the progression of renal insufficiency
- control ECF volume: Na⁺ restriction (2 g/d intake), diuretic, dialysis with end-stage disease
- ACEI or ARB may provide added benefit (monitor K⁺ and Cr) if there is significant proteinuria (>300 mg/d)

Cystic Diseases of the Kidney

- characterized by epithelium-lined cavities filled with fluid or semisolid debris within the kidneys
- includes: simple cysts (present in 50% of population >50), medullary cystic kidney, medullary sponge kidney, polycystic kidney disease (autosomal dominant and recessive), and acquired cystic kidney disease (in chronic hemodialysis patients)

Adult Polycystic Kidney Disease

- autosomal dominant; at least 2 genes: *PKD1* (chr 16p) and *PKD2* (chr 4q)
- *PKD1* (1:400), *PKD2* (1:1,000) accounts for about 10% of cases of renal failure
- patients generally heterozygous for mutant *PKD* gene but accumulate a series of second 'somatic hits' precipitating the condition
- *PKD* gene defect leads to abnormal proliferation and apoptosis of tubular epithelial cells leading to cyst growth

Hypercalcemia complicates many cancers and can cause multiple kinds of renal disorders (renal vasoconstriction with reduced GFR, salt-wasting with volume depletion, risk of calcium kidney stones)

- most common extrarenal manifestations: multiple asymptomatic hepatic cysts (33%), mitral valve prolapse (25%), cerebral aneurysm (10%), diverticulosis
- polycystic liver disease rarely causes liver failure
- less common extrarenal manifestations: cysts in pancreas, spleen, thyroid, ovary, seminal vesicles, and aorta

Signs and Symptoms

- often asymptomatic; discovered incidentally on imaging or by screening those with FHx
- acute abdominal flank pain/dull lumbar back pain
- hematuria (frequently initial sign is microscopic hematuria, otherwise gross hematuria)
- nocturia (urinary concentrating defect)
- rarely extra-renal presentation (e.g. ruptured berry aneurysm, diverticulitis)
- HTN (increased renin due to focal compression of intrarenal arteries by cysts) (60-75%)
- \pm palpable kidneys

Common Complications

- urinary tract and cyst infections, HTN, chronic renal failure, nephrolithiasis (5-15%), flank and chronic back pain

Clinical Course

- polycystic changes are always bilateral and can present at any age
- clinical manifestations rare before age 20-25
- kidneys are normal at birth but may enlarge to 10x normal size
- variable progression to renal functional impairment (ESRD in up to 50% by age 60)

Investigations

- radiographic diagnosis: best accomplished by renal U/S (enlarged kidneys, multiple cysts throughout renal parenchyma, increased cortical thickness, splaying of renal calyces)
- CT abdo with contrast (for equivocal cases, occasionally reveals more cystic involvement)
- gene linkage analysis for *PKD1* for asymptomatic carriers
- Cr, BUN, urine R&M (to assess for hematuria)

Treatment

- goal: to preserve renal function by prevention and treatment of complications
- educate patient and family about disease, its manifestations, and inheritance pattern
- genetic counselling: transmission rate 50% from affected parent
- prevention and early treatment of urinary tract and cyst infections (avoid instrumentation of GU tract)
- TMP/SMX, ciprofloxacin: able to penetrate cyst walls, achieve therapeutic levels
- adequate hydration to prevent stone formation
- avoid contact sports due to greater risk of injury to enlarged kidneys
- screen for cerebral aneurysms if family history of aneurysmal hemorrhages
- monitor blood pressure and treat HTN with ACEI
- dialysis or transplant for ESRD (disease does not recur in transplanted kidney)
- may require nephrectomy for symptomatic relief of pain or due to recurrent infections

Extra-Renal Manifestations of PKD

- Hepatic cysts
- Mitral valve prolapse
- Cerebral aneurysms
- Diverticulosis

Autosomal Recessive Polycystic Kidney Disease

- 1:20,000 incidence
- prenatal diagnosis by enlarged kidneys
- perinatal death from respiratory failure
- patients who survive perinatal period develop CHF, HTN, CKD
- treated with dialysis, kidney and/or liver transplant

Medullary Sponge Kidney

- common, autosomal dominant, usually diagnosed in 4th-5th decades
- multiple cystic dilatations in the collecting ducts of the medulla
- renal stones, hematuria, and recurrent UTIs are common features
- an estimated 10% of patients who present with renal stones have medullary sponge kidney
- nephrocalcinosis on abdominal x-ray in 50% patients, often detect asymptomatic patients incidentally
- diagnosis: contrast filled medullary cysts on IVP leading to characteristic radial pattern ("bouquet of flowers"), "Swiss cheese" appearance on histological cross-section
- treat UTIs and stone formation as indicated
- does not result in renal failure

End Stage Renal Disease

- ESRD represents an irreversible decline in kidney function requiring renal replacement therapy

Presentation of End Stage Renal Disease

1. Volume Overload

- due to increase in total body Na^+ content
- signs: weight gain, HTN, pulmonary or peripheral edema

2. Electrolyte Abnormalities

- high
 - K^+ (decreased renal excretion, increased tissue breakdown)
 - PO_4^{3-} (decreased renal excretion, increased tissue breakdown)
 - Ca^{2+} (rare; happens during recovery phase after rhabdomyolysis-induced AKI or in settings where hypercalcemia contributes to renal failure, such as in multiple myeloma or sarcoidosis)
 - uric acid
- low
 - Na^+ (failure to excrete excessive water intake)
 - Ca^{2+} (decreased Vitamin D activation, hyperphosphatemia, hypoalbuminemia)
 - HCO_3^- (especially with sepsis or severe heart failure)

3. Uremic Syndrome

- manifestations result from retention of urea and other metabolites as well as hormone deficiencies

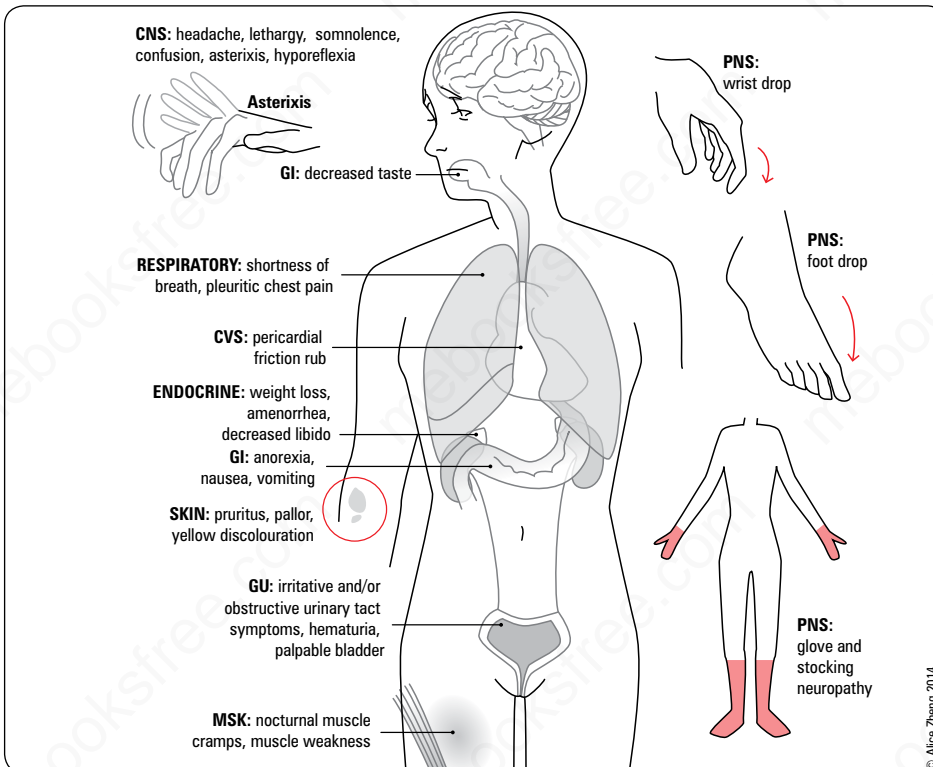

Figure 20. Signs and symptoms of end stage renal disease

Complications

- CNS: decreased LOC, stupor, seizure
- CVS: cardiomyopathy, CHF, arrhythmia, pericarditis, atherosclerosis
- GI: peptic ulcer disease, gastroduodenitis, AVM
- hematologic: anemia, bleeding tendency (platelet dysfunction), infections
- endocrine
 - decreased testosterone, estrogen, progesterone
 - increased FSH, LH
- metabolic
 - renal osteodystrophy: secondary increased PTH due to decreased Ca^{2+} , high PO_4^{3-} , and low active vitamin D
 - osteitis fibrosa cystica
 - hypertriglyceridemia, accelerated atherogenesis
 - decreased insulin requirements, increased insulin resistance
- dermatologic: pruritus, ecchymosis, hematoma, calciphylaxis (vascular Ca^{2+} deposition)

Renal Replacement Therapy

Dialysis

Indications for Dialysis in Chronic Kidney Disease

Table 16. Indications for Dialysis

Absolute Indications	Relative Indications
Volume overload*	Anorexia
Hyperkalemia*	Decreased cognitive functioning
Severe metabolic acidosis*	Profound fatigue and weakness
Neurologic signs or symptoms of uremia (encephalopathy, neuropathy, seizures)	Severe anemia unresponsive to erythropoietin
Uremic pericarditis	Persistent severe pruritus
Refractory accelerated HTN	Restless leg syndrome
Clinically significant bleeding diathesis	
Persistent severe N/V	

*Unresponsive to medications

- hemodialysis: blood is filtered across a semipermeable membrane removing accumulated toxic waste products, solutes, excess fluid (ultrafiltration), and restoring buffering agents to the bloodstream
 - available as intermittent (e.g. 3-6x/wk), continuous (CVVHD) or sustained low efficiency (SLED)
 - can be delivered at home or in-centre, nocturnal
 - vascular access can be achieved through a central line, an artificial graft, or an AV fistula
- patients with CKD should be referred for surgery to attempt construction of a primary AV fistula when their eGFR is <20 mL/min, the serum Cr level quoted as >350 μmol/L, or within 1 yr of an anticipated need
- peritoneal dialysis: peritoneum acts as a semipermeable membrane similar to hemodialysis filter
 - advantages: independence, fewer stringent dietary restrictions, better rehabilitation rates
 - available as continuous ambulatory (CAPD; 4-5 exchanges per day) or cyclic (CCPD; machine carries out exchanges overnight)
- refer patients with chronic renal disease to a nephrologist early on to facilitate treatment and plan in advance for renal replacement therapy (RRT)

Table 17. Peritoneal Dialysis vs. Hemodialysis

	Peritoneal Dialysis	Hemodialysis
Rate	Slow	Fast
Location	Home	Hospital (usually)
Ultrafiltration	Osmotic pressure via dextrose dialysate	Hydrostatic pressure
Solute Removal	Concentration gradient and convection	Concentration gradient and convection
Membrane	Peritoneum	Semi-permeable artificial membrane
Method	Indwelling catheter in peritoneal cavity	Line from vessel to artificial kidney
Complications	Infection at catheter site Bacterial peritonitis Metabolic effects of glucose Difficult to achieve adequate clearance in patients with large body mass	Vascular access (clots, collapse) Bacteremia Bleeding due to heparin Hemodynamic stress of extracorporeal circuit Disequilibrium syndrome (headache, cerebral edema, hypotension, nausea, muscle cramps related to solute/water flux over short time)
Preferred When	Residual renal function Success depends on presence of residual renal function Hemodynamic instability	Comorbidities, no renal function Residual renal function not as important History of abdominal surgery

How to Write Dialysis Orders (MUST BE INDIVIDUALIZED)

- Filter Type (e.g. F80)
- Length (e.g. 4 h 3x/wk or 2 h daily)
- Q Blood Flow (max 500 cc/min)
- Ultrafiltration (e.g. 2 L or to target dry weight)
- Na⁺ 140 (can be adjusted by starting at 155 and "ramping" down to minimize cramping)
- K⁺ (based on serum K⁺)

Serum K ⁺	Dialysate
4-6	1.5
3.5-4	2.5
<3.5	3.5
- Ca²⁺ 1.25
- HCO₃⁻ 40
- Heparin (none, tight [500 U/h] or full [1000 U/h])
- IV fluid to support BP (e.g. NS)

When to Initiate Dialysis

- CrCl <20 mL/min
- Educate patient regarding dialysis; if not a candidate for peritoneal dialysis, make arrangements for AV fistula
- CrCl <15 mL/min
- Weigh risk and benefits for initiating dialysis
- CrCl <10 mL/min
- Dialysis should be initiated

NOTE

- Cockcroft-Gault equation (or MDRD equation) should be used to measure kidney function
- Monitor for uremic complications
- Significant benefits in quality of life can occur if dialysis started before CrCl <15 mL/min
- It is unclear whether patients who start dialysis early have increased survival
- A preemptive transplant can be considered if patient is stable, in order to avoid dialysis

Source: National Kidney Foundation Kidney Disease Outcomes Quality Initiative

Commonly Used Immunosuppressive Drugs

Calcineurin inhibitors

- Cyclosporine
- Tacrolimus

Antiproliferative medications

- Mycophenolate mofetil
- Azathioprine

Other agents

- Sirolimus
- Prednisone

Anti-lymphocyte antibodies

- Thymoglobulin
- Basiliximab

Indications for Dialysis (refractory to medical therapy)

AE IOU

- Acidosis
- Electrolyte imbalance (K⁺)
- Intoxication
- Overload (fluid)
- Uremia (encephalopathy, pericarditis, urea >35-50 mM)

Renal Transplantation

- provides maximum replacement of GFR
- preferred modality of RRT in CKD, not AKI
 - best way to reverse uremic signs and symptoms
 - renal transplantation has been shown to have improved long-term patient survival and greater quality of life over dialysis
- native kidneys usually left *in situ*
- 2 types: deceased donor, living donor (related or unrelated)
- living donor transplants have been shown to have better outcomes than deceased donor transplants
- kidney transplanted into iliac fossa, transplant renal artery anastomosed to external iliac artery of recipient
- 1 yr renal allograft survival rates $\geq 90\%$

Complications

- #1 cause of mortality in transplanted patients is cardiovascular disease
- de novo GN (usually membranous)
- new-onset DM (often due to prednisone and calcineurin inhibitors, especially tacrolimus)
- graft rejection
- acute rejection: graft site tenderness, rise in Cr, oliguria, \pm fever, although symptoms are uncommon
- early allograft damage caused by episodes of acute rejection and acute peritransplant injuries
- transplant glomerulopathy from antibody injury causes nephrotic proteinuria
- cyclosporine or tacrolimus nephropathy (see *Small Vessel Disease*, NP29)
- BK virus (polyoma virus) nephropathy can result from over-immunosuppression and lead to graft loss
- leading causes of late allograft loss: interstitial fibrosis/tubular atrophy (IFTA) and death with functioning graft
- depends on immunologic and nonimmunologic factors (HTN, hyperlipidemia, age of donor, quality of graft, new onset DM)
- infections (CMV, PJP and other opportunistic infections usually occur between 1 and 6 mo post-transplant)
- malignancy (skin cancer, Kaposi's sarcoma, non-Hodgkin's lymphoma)

Survival Benefit with Kidney Transplants from HLA-Incompatible Live Donors

NEJM 2016;374:940-950

Purpose: To assess whether there is a survival advantage to receiving a kidney from HLA-incompatible donors compared to remaining on the waiting list for a possible matched deceased donor kidney.

Study: Retrospective, multi-centre analysis

Population: 1025 individuals who received HLA-incompatible live donor kidneys compared to two different controls: individuals waiting and possibly receiving a deceased donor kidney (N=5125), or individuals ultimately not receiving a kidney transplant (N=5125).

Outcome: Survival, tracked for up to 8 years.

Results: Individuals who received HLA-incompatible kidneys had increased survival compared to either control group for time points at 1 year, 5 years, and 8 years post-transplant ($p < 0.001$). After 8 years non-matched kidney recipients had 76.5% survival compared to 43.9% for individuals who ultimately did not receive a kidney transplant. Survival advantage was significant regardless of how the recipient anti-HLA antibodies were detected.

Conclusions: Individuals who received HLA-incompatible kidneys had significantly improved long-term survival compared to individuals who waited for compatible deceased donor kidneys.

Common Medications

Table 18. Common Medications in Nephrology

Classification	Examples	Site of Action	Mechanism of Action (Secondary Effect)	Indication	Dosing	Adverse Effects
Loop Diuretics	furosemide (Lasix®) bumetanide (Bumex®/Buinex®) ethacrynate (Edecrin®) torsemide (Demadex®)	Thick ascending limb of Loop of Henle	\downarrow Na ⁺ /K ⁺ /2Cl ⁻ transport \pm renal and peripheral vasodilatory effects (K ⁺ loss; \uparrow H ⁺ secretion; \uparrow Ca ²⁺ excretion)	Management of edema secondary to CHF, nephrotic syndrome, cirrhotic ascites; \uparrow free water clearance (e.g. in SIADH-induced hyponatremia), \downarrow BP (less effective due to short action)	furosemide: edema: 20-80 mg IV/IM/ PO q6-8h (max 600 mg/d) until desired response HTN: 20-80 mg/d PO OD/ bid dosing	Allergy in sulfa-sensitive individuals Electrolyte abnormalities; hypokalemia, hyponatremia, hypocalcemia, hypercalcaemia (with stone formation) Volume depletion with metabolic alkalosis Precipitates gouty attacks
Thiazide Diuretics	hydrochlorothiazide (HCTZ) chlorthalidone (Diurol®) indapamide (Lozol®, Lozide®) metolazone (Zaroxolyn®) chlorthalidone (Hygroton®)	Distal convoluted tubule	Inhibit Na ⁺ /Cl ⁻ transporter (K ⁺ loss; \uparrow H ⁺ secretion; \uparrow Ca ²⁺ excretion)	1st line for essential HTN Treatment of edema Idiopathic hypercalcaemia and stones Diabetes insipidus (nephrogenic)	HCTZ: edema: 25-100 mg PO OD HTN: 12.5-25 mg PO OD (max 50 mg/d) nephrolithiasis/hypercalcaemia: 25-100 mg OD	Hypokalemia Increased serum urate levels Precipitates gouty attacks, hypercalcaemia Elevated lipids Glucose intolerance
Potassium-Sparing Diuretics	spironolactone (Aldactone®) triamterene (Dyrenium®) amiloride (Midamor®)	Cortical collecting duct (\downarrow Na ⁺ reabsorption)	Aldosterone antagonist (spironolactone) Block Na ⁺ channels (triamterene and amiloride)	Reduces K ⁺ loss caused by other diuretics Edema/hypovolemia Severe CHF, ascites (spironolactone), cystic fibrosis (amiloride \downarrow viscosity of secretions)	spironolactone: 25-200 mg/d OD/bid dosing HTN: 50-200 mg/d OD/bid dosing Hyperaldosteronism: 100-400 mg/d OD/bid dosing amiloride: edema/HTN: 5-10 mg PO OD	Hyperkalemia (caution with ACEI) Triamterene can be nephrotoxic (rare) Nephrolithiasis Gynecomastia (estrogenic effect of spironolactone)
Combination Agents	Dyazide® (triamterene + HCTZ) Aldactazide® (spironolactone + HCTZ) Moduretic® (amiloride + HCTZ) Vaseretic® (enalapril + HCTZ) Zestoretic® (lisinopril + HCTZ)		Combination of ACEI and thiazide have a synergistic effect	Combine K ⁺ -sparing drug with thiazide to reduce hypokalemia		
Osmotic Diuretics	mannitol (Osmitol®) glycerol urea	Renal tubules (proximal and collecting duct)	Non-reabsorbable solutes increase osmotic pressure of glomerular filtrate – inhibits reabsorption of water and \uparrow urinary excretion of toxic materials	To \downarrow intracranial or intraocular pressure Mobilization of excess fluid in renal failure or edematous states	mannitol: \downarrow ICP: 0.25-2 g/kg IV over 30-60 min	Transient volume expansion Electrolyte abnormalities (\downarrow / \uparrow Na ⁺ , \downarrow / \uparrow K ⁺)

Table 18. Common Medications in Nephrology (continued)

Classification	Examples	Site of Action	Mechanism of Action (Secondary Effect)	Indication	Dosing	Adverse Effects
ACEI	ramipril (Altace®) enalapril (Vasotec®) lisinopril (Prinivil®) trandolapril (Mavik®) captopril (Capoten®)	Lungs Tissues diffusely	Inhibits angiotensin converting enzyme, preventing formation of angiotensin II Prevents angiotensin II vasoconstricting vascular smooth muscle → net vasodilation → ↓ BP Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules → ↑ Na ⁺ and H ₂ O excretion → ↓ BP Reduces fibrosis and atherogenesis	HTN Cardioprotective effects (see Cardiology and Cardiac Surgery, C49) Renoprotective effects	ramipril: HTN: 2.5-20 mg PO OD/bid dosing renoprotective use; 10 mg PO OD trandolapril: HTN; 1-4 mg PO OD	Cough Asthma Hyperkalemia Angioedema Agranulocytosis (captopril) AKI Teratogenic
ARB	losartan (Cozaar®) candesartan (Atacand®) irbesartan (Avapro®) valsartan (Diovan®) telmisartan (Micardis®) eprosartan (Teveten®) olmesartan (Olmotec®)	Vascular smooth muscle, adrenal cortex, proximal tubules	Competitive inhibitor at the angiotensin II receptor: prevents angiotensin II vasoconstricting action on vascular smooth muscle → ↓ BP Prevents angiotensin II mediated aldosterone release from adrenal cortex and action on proximal renal tubules → ↑ Na ⁺ and H ₂ O excretion	HTN Cardioprotective effects (see Cardiology and Cardiac Surgery, C49) Renoprotective effects	HTN: losartan 25-100 mg PO OD candesartan 8-32 mg PO OD irbesartan 150-300 mg PO OD valsartan 80-320 mg PO OD telmisartan 20-80 mg PO OD eprosartan 400-800 mg PO OD olmesartan 20-40 mg PO OD	Hyperkalemia Caution – reduce dose in hepatic impairment AKI Teratogenic
Renin Antagonists	aliskiren (Rasilez®)	Direct renin antagonist	Inhibits renin production and activity Cardioprotective and renoprotective abilities being evaluated	HTN	aliskiren 150-300 mg PO OD	Hyperkalemia

Landmark Nephrology Trials

Trial	Reference	Results
4D	<i>NEJM</i> 2005;353:238-48	Patients with type 2 DM receiving maintenance hemodialysis were randomized to 20 mg of atorvastatin per day or matching placebo; no difference in composite index of death from cardiac causes, nonfatal myocardial infarction, and stroke
AASK	<i>JAMA</i> 2001;285:2719-28	Ramipril, compared with amlodipine, slows progression of hypertensive renal disease and proteinuria and may benefit patients without proteinuria as well
ACCOMPLISH	<i>NEJM</i> 2008;359:2417-20	Combination treatment with an ACEI and a CCB (benazepril-amlodipine) was more successful than a combination of ACEI and thiazide diuretic (benazepril-HCTZ) in reducing cardiovascular events in patients with HTN who were at risk for such events
ACEI and Diabetic	<i>NEJM</i> 1993;329:1456-62	Captopril protects against deterioration in renal function in insulin-dependent diabetic nephropathy and is significantly more effective than blood pressure control alone
ALERT	<i>Lancet</i> 2003;361:2024-31	The use of fluvastatin in renal transplant recipients did not significantly decrease the risk of the occurrence of a major adverse cardiac event (defined as cardiac death, non-fatal MI, or coronary intervention procedure) compared with placebo; however, there was a significant reduction in cardiac deaths or non-fatal MI
ALTITUDE	<i>Early Termination</i> (Unpublished Results; protocol – NDT 2009;24:166 ³ :71)	Combining Aliskiren with ACEI or ARB in high-risk patients with type 2 DM leads to increased incidence of nonfatal stroke, hyperkalemia, and hypotension
ASTRAL	<i>NEJM</i> 2009;361:195 ³ :62	Renal artery revascularization compared to medical therapy does not improve renal function, BP, renal or cardiovascular events, or mortality, and carries significant operative risks
AURORA	<i>NEJM</i> 2009;360:1395-407	Patients receiving maintenance hemodialysis randomized to rosuvastatin 10 mg daily or placebo; rosuvastatin lowered the LDL cholesterol level but had no significant effect on the composite primary end point of death from cardiovascular causes, nonfatal myocardial infarction, or nonfatal stroke
BENEDICT	<i>NEJM</i> 2004;351:1941-51	Treatment with ACEI trandolapril alone or trandolapril combined with verapamil decreased the incidence of microalbuminuria in patients with type 2 DM and HTN with normoalbuminuria
CHOIR	<i>NEJM</i> 2006;355:2085-98	Patients with CKD were randomly assigned to receive a dose of epoetin alfa targeted to achieve a hemoglobin level of 135 g/L or 113 g/L; the higher target group had an increased risk of death, myocardial infarction, hospitalization for congestive heart failure (without renal replacement therapy), or stroke
CORAL	<i>NEJM</i> 2014; 370:1 ³ :22	Renal-artery stenting did not confer a significant benefit with respect to the prevention of renal or cardiac events when added to comprehensive, multifactorial medical therapy in people with atherosclerotic renal-artery stenosis and hypertension or chronic kidney disease
CREATE	<i>NEJM</i> 2006;355:2071-84	Patients with CKD (15-35 mL/min) and mild to moderate anemia (110-125 g/L) were randomized to normal (130-150 g/L) or sub-normal (105-115 g/L) hemoglobin levels; early and complete correction of hemoglobin did not reduce the risk of cardiovascular events

Landmark Nephrology Trials (continued)

Trial	Reference	Results
DETAIL	<i>NEJM</i> 2004;351:1952-61	The ARB telmisartan and the ACEI enalapril are equally effective in slowing renal function deterioration in type 2 DM with mild to moderate HTN and early nephropathy
ELITE-SYMPHONY	<i>NEJM</i> 2007;357:2562-75	Daclizumab induction, MMF, steroids, and low-dose tacrolimus effectively maintain stable renal function following renal transplantation, without the negative effects on renal function commonly reported for standard CNi regimens
FHN	<i>NEJM</i> 2010;363:2287-300	Patients were randomized to dialysis 6x/wk (frequent) or 3x/wk (conventional); frequent hemodialysis was associated with improvement in composite outcomes of death, or change in left ventricular mass and death, or change in a physical-health composite score; frequent hemodialysis caused more frequent interventions related to vascular access
HEMO	<i>NEJM</i> 2002;347:2010-19	Use of high dose dialysis or high flux membranes versus standard dose or low flux in thrice-weekly dialysis does not improve survival or outcomes; possible benefit in cardiac-related outcomes with high flux membranes
IDEAL	<i>NEJM</i> 2010;363:609-19	Patients with progressive CKD and GFR between 10 and 15 mL/min randomized to initiate dialysis at GFR of 10-14 mL/min (early) or 5-7 mL/min (late); early initiation of dialysis in patients with stage G5 CKD was not associated with an improvement in survival or clinical outcomes
IDNT	<i>NEJM</i> 2001;345:851-60	Treatment with irbesartan reduced the risk of developing end-stage renal disease and worsening renal function in patients with type 2 DM and diabetic nephropathy
IRMA	<i>NEJM</i> 2001;345:870-8	Irbesartan is renoprotective independently of its blood pressure lowering effect in patients with type 2 DM and microalbuminuria
MDRD	<i>Ann Intern Med</i> 1995;123:754-62	Patients with proteinuria of more than 1 g/d should have a target BP <125/75 mmHg; patients with proteinuria of 0.25 to 1.0 g/d should have a target BP <130/80 mmHg
ONTARGET	<i>Lancet</i> 2008;372:547-53	Telmisartan and ramipril monotherapy reduced proteinuria and rise in Cr in patients with high vascular risk; combination of the two agents led to increased acute renal failure episodes, syncope, and hypotension
REIN	<i>Lancet</i> 1999;354:359-64	In non-diabetic nephropathy, ACEI were renoprotective in patients with non-nephrotic range proteinuria
REIN2	<i>Lancet</i> 2005;365:939-46	In non-diabetic nephropathy already on ACEI, no further benefit from intensified BP control (sBP/dBP <130/80 mmHg) by adding a CCB versus conventional BP control (dBP <90 mmHg) on ACEI alone
RENAAL	<i>NEJM</i> 2001;345:861-9	Losartan conferred significant renal benefits in patients with type 2 DM and nephropathy and was generally well-tolerated
RENAL	<i>NEJM</i> 2009;361:1627-38	High intensity continuous renal-replacement therapy in AKI does not improve survival or outcomes compared to low intensity treatment, and is associated with higher rates of hypophosphatemia
Rituximab in Children with Steroid-Dependent Nephrotic Syndrome	<i>JASN</i> 2015;26 DOI: ASN.2014080799	Rituximab is non-inferior to steroids in maintaining remission in juvenile steroid dependent nephrotic syndrome
ROAD	<i>JASN</i> 2007;18:1889-98	Uptitration of either ACEI benazepril or ARB losartan to optimal anti-proteinuria doses conferred benefit on renal outcome in patients without DM who had proteinuria and renal insufficiency
ROADMAP	<i>NEJM</i> 2011;364:907-17	The use of the ARB olmesartan was more effective than placebo in delaying the onset of microalbuminuria in patients with type 2 DM, normoalbuminuria, and good blood pressure control; however, a higher rate of fatal cardiovascular events was found amongst patients with preexisting coronary heart disease in the olmesartan group
SHARP	<i>Lancet</i> 2011;377:2181-92	Randomized placebo-controlled trial in patients with CKD and no history of MI or coronary revascularization took simvastatin 20 mg plus ezetimibe 10 mg daily versus matching placebo; simvastatin 20 mg plus ezetimibe 10 mg daily resulted in reduction of LDL cholesterol with associated reduction of major atherosclerotic events in patients with CKD
SPRINT	<i>NEJM</i> 2015;373:210 ³ :2116	A lower blood pressure target of 120/80 reduced the risk of composite cardiovascular events in a hypertensive patient population
TREAT	<i>NEJM</i> 2009;361:2019-32	Patients with type 2 DM, CKD, and anemia were randomized to darbepoetin targeting a hemoglobin of 13 g/dL or placebo; darbepoetin did not reduce the risk of death, a cardiovascular event, or a renal event, and was associated with an increased risk of stroke
Tolvaptan in ADPKD	<i>NEJM</i> 2012;367: 2407-18	Tolvaptan (vs. placebo) slowed the increase in total kidney volume and decline in kidney function over a 3-year period in patients with ADPKD but was associated with a higher discontinuation rate, due to adverse events
SGLT-2 inhibitor use and diabetic	<i>J Am Soc Nephrol</i> 2017; 28:368-375	Canagliflozin, a sodium-glucose cotransporter 2 inhibitor, slowed the progression of renal disease over 2 years in patients with type 2 diabetes, and may confer renoprotective effects independently of glycemic control

Approach to the Neurological Complaint

Lesion Localization

• cortical

- contralateral paresis (with differential effect on face and arm vs. leg)
- UMN injury (hyperreflexia, Babinski sign, spasticity, no atrophy, pyramidal pattern of weakness)
- cortical sensory loss (hemisensory loss, position sense, two-point discrimination, graphesthesia, stereognosis)
- dominant hemisphere (aphasia, alexia, agraphia, acalculia, left-right disorientation)
- non-dominant hemisphere (hemineglect, dysprosody, amusia, constructional apraxia)
- homonymous hemianopia/quadrantanopia
- gaze deviation
- seizure
- agnosia (visual, auditory)
- apraxia
- alien hand syndrome

• subcortical

- internal capsule: contralateral paresis with equal face, arm, leg involvement without sensory/cortical deficits; contralateral dysmetria/clumsiness and leg paresis
- basal ganglia: pill-rolling tremor, bradykinesia, festinating gait, hemiballismus, chorea, dystonic posture
- thalamus: dense sensory loss, contralateral severe pain

• brainstem (bulbar)

- crossed hemiplegia or sensory loss (i.e. ipsilateral face, contralateral body)
- ipsilateral cerebellar (dysmetria, rapid alternating movements, tandem gait)
- nystagmus toward lesion, diplopia, INO (impaired adduction on contralateral gaze)
- dysphagia, dysarthria
- hearing loss, vertigo

• cerebellum

- ipsilateral ataxia (unsteadiness, incoordination)
- dysmetria, intention tremor
- dysdiadochokinesia
- wide-based gait, truncal titubation (staggering, reeling, lurching)
- scanning speech (explosive speech with noticeable pauses and accentuated syllables)
- nystagmus, distorted smooth pursuit, oscillopsia

• spinal cord

- bilateral motor and/or sensory deficits below the lesion without facial involvement
- ataxia, sensory level (sharp line below which there is decreased sensation); suspended "cape-like" sensory level
- LMN signs (flaccid paresis, hypotonia, hyporeflexia, atrophy, fasciculations) at level of lesion; UMN signs below lesion (marked spasticity and Babinski)
- bowel, bladder, sexual dysfunction
- saddle anesthesia
- ataxia

• nerve root

- multiple peripheral nerve involvement
- myotomal/dermatomal deficits
- back/neck pain radiating to leg/arm

- **peripheral nerve**
 - distal “stocking-glove distribution” sensory loss
 - LMN signs (hypotonia, hyporeflexia, fasciculations, atrophy)
- **neuromuscular junction**
 - fluctuating/fatiguable symptoms
 - facial and limb weakness
 - dysphonia, dysarthria
 - ophthalmoparesis (diplopia), ptosis
- **muscle**
 - symmetric proximal weakness (climbing stairs, getting up from chair) without sensory deficits
 - muscle tenderness
 - muscle atrophy

The Neurological Exam

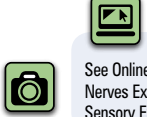

General Exam and Mental Status

- **vitals:** pulse (especially rhythm), BP, RR, temperature
- **H&N:** meningismus, head injury/bruises (signs of basal skull fracture: Battle’s sign, raccoon eyes, hemotympanum, CSF rhinorrhea/otorrhea), tongue biting
- **CVS:** carotid bruits, heart murmurs
- **mental status:** orientation (person, place, time), LOC (GCS) (see [Emergency Medicine, ER4](#))
 - GCS/15 – Motor/6, Verbal/5 (T= intubated), Eyes/4
- **cognition**
 - Folstein MMSE – /30 (note: dementia is a clinical diagnosis and is not diagnosed by cognitive testing)
 - MoCA – /30 (≥26 is considered normal)
 - frontal lobe testing (for perseveration – i.e. go/no-go test)
 - clock drawing

Cranial Nerve Exam

Table 1. Cranial Nerve Examination and Associated Deficits

Cranial Nerve	Recommended Physical Exams	Signs/Symptoms of Deficit
Olfactory (CN I)	Odour sensation: test each nostril separately	Anosmia (can be associated with loss of taste)
Optic (CN II)	Visual acuity: test each eye individually; best corrected vision Test visual fields Assess pupils: direct and consensual pupillary reaction (afferent), swinging flashlight test (for RAPD) Fundoscopy: optic disc edema and pallor, venous pulsations, hemorrhages Colour vision testing (Ishihara plates)	Blindness Absence of light reflexes, RAPD
Oculomotor (CN III)	Assess extraocular movements and nystagmus Test efferent limb of pupillary light response Assess size and shape of pupils; accommodation and saccadic eye movements Test for ptosis (levator palpebrae superioris)	Eyes deviated down and out; can demonstrate mydriasis
Trochlear (CN IV)	Test movement of superior oblique	Vertical diplopia; may tilt head towards unaffected side; affected eye cannot turn inward and downward
Trigeminal (CN V)	Test sensation above supraorbital ridge (V1), buccal area (V2), mandible (V3) Test corneal reflex (afferent limb) Assess motor function: temporalis, masseter, pterygoids, jaw jerk reflex	Loss of facial sensations and corneal reflex on stimulation ipsilaterally, weakness and wasting of muscles of mastication, deviation of open jaw to ipsilateral side; trigeminal neuralgia
Abducens (CN VI)	Test movement of lateral rectus	Horizontal diplopia, esotropia (convergent strabismus) and abductor paralysis of ipsilateral eye
Facial (CN VII)	Test sensorimotor nerve function with muscles of facial expression Test efferent limb of corneal reflex Visceral sensory nerve function: to anterior 2/3 of the tongue Visceral motor nerve function: to salivary and lacrimal glands	Paralysis of ipsilateral upper and lower facial muscles Loss of lacrimation Decreased salivation, dry mouth Loss of taste to anterior 2/3 of the tongue ipsilaterally LMN lesion = ipsilateral facial weakness UMN lesion = contralateral facial weakness, sparing the brow bilaterally

See Online Atlas for Cranial Nerves Exam, Motor Exam, and Sensory Exam Techniques

Battle’s sign = mastoid ecchymosis
Raccoon eyes = periorbital ecchymosis

If patient has not brought their glasses, have them look through a pinhole for best corrected vision

When testing CN I, avoid noxious smells like ammonia, as this tests CN V

Screening Neurologic Exam

- Mental status: orientation (person, place, time), obeys commands, GCS
- Head and neck: examine for lacerations, contusions, deformities, signs of basal skull fracture, flex neck for meningismus if c-spine injury has been ruled out
- Cranial nerve exam: visual fields ± fundoscopy, pupil size and reactivity, extraocular movements, facial strength, hearing to finger rub
- Motor: tone, power in deltoids, triceps, wrist extensors, hand interossei, iliopsoas, hamstrings, ankle dorsiflexors, pronator drift
- Coordination: finger tapping, finger-to-nose, heel-knee-shin
- Gait: tandem gait, heel walking
- Reflexes: plantar, biceps, triceps, patellar, ankle, Babinski
- Sensation: all 4 limbs, including double simultaneous stimulation, vibration sense at great toes

Table 1. Cranial Nerve Examination and Associated Deficits (continued)

Cranial Nerve	Recommended Physical Exams	Signs/Symptoms of Deficit
Vestibulocochlear (CN VIII)	Vestibular function - nystagmus, caloric reflexes Cochlear function - whisper test, Rinne, Weber	Vertigo, disequilibrium, and nystagmus Sensorineural hearing loss
Glossopharyngeal (CN IX)	Assess vocal cord function and gag reflex Assess taste to posterior third of the tongue (bitter and sour taste)	Loss of taste in posterior third of ipsilateral tongue Loss of gag reflex and dysphasia Unilateral lesion is rare
Vagus (CN X)	Assess vocal cord function and gag reflex Observe uvula deviation and palatal elevation Assess swallowing	Loss of gag reflex, dysphagia, hoarse voice Paralysis of soft palate (failed elevation) Deviation of uvula to contralateral side of lesion; anesthesia of pharynx and larynx ipsilaterally
Accessory (CN XI)	Assess strength of trapezius (shoulder shrug) and sternocleidomastoid muscles (head turn)	Ipsilateral shoulder weakness and turning head to opposite side
Hypoglossal (CN XII)	Inspect tongue for signs of lateral deviation, atrophy, fasciculations, asymmetry of movement and strength	Wasting of ipsilateral tongue muscles and deviation to ipsilateral side on protrusion

Motor Exam

- bulk: atrophy, asymmetry
- tone: hypotonia (flaccid), hypertonia (spasticity, rigidity, paratonia), cogwheeling
- power: pronator drift, asymmetric forearm rolling test (satellite sign)
- reflexes: deep tendon reflexes, abdominal reflexes, primitive reflexes, Babinski sign, Hoffmann sign, clonus
- abnormal movements: tremors, chorea, dystonia, dyskinesia, hemiballism, myoclonus, athetosis, tics, fasciculations, myokymia
- abnormal posturing: decorticate (upper extremity flexion, lower extremity extension), decerebrate (extremity extension)

Table 2. Localization of Motor Deficits

	LMN	UMN	Extrapyramidal
Muscle Tone	Flaccid	Spastic	Rigid
Involuntary Movements	Fasciculations	None	None
Reflexes	Decreased	Increased	Normal
Plantar Reflex	Down-going (flexor)	Up-going (extensor, i.e. Babinski sign)	Down-going (flexor)
Pattern of Muscle Weakness	Proximal, distal, or focal	Pyramidal pattern: look for hemiparetic gait (flexed arm, extended legs) Upper extremities: extensors weaker than flexors Lower extremities: flexors weaker than extensors	None

Table 3. Overview of Neuromuscular Diseases

	Motor Neuron Disease (i.e. ALS)	Peripheral Neuropathy	Neuromuscular Junction	Myopathy
SIGNS AND SYMPTOMS				
Weakness	Segmental and asymmetrical, distal → proximal	Distal (except GBS) but may be asymmetrical	Proximal and fatigable (e.g. MG), or weak then recovers (e.g. LEMS)	Proximal
Fasciculations	Yes	Yes	No	No
Reflexes	Increased	Decreased/absent	Normal	Normal (until late)
Sensory	No	Yes	No	No
Autonomic*	No	Yes	No	No
TESTS				
EMG	Denervation and reinnervation	Signs of demyelination ± axonal loss	Decremental response, Jitter on single fibre EMG	Small, short motor potentials
NCS	Normal	Abnormal	Normal	Normal
Muscle Enzyme	Normal	Normal	Normal	Increased

*e.g. orthostatic hypotension, anhidrosis, visual blurring, urinary hesitancy or incontinence, constipation, erectile dysfunction

CN Innervation of EOM
LR: CN VI, SO: CN IV, Other: CN III

Contraction of the left sternocleidomastoid turns the head right

Calorics: Brainstem Test
Describe nystagmus by direction of fast component

COWS
Cold
Opposite
Warm
Same

Upper Motor Neuron Tests
Babinski Reflex: 'Up-going' big toe ± fanning of toes indicates an UMN lesion
Hoffmann's Reflex: Flexion of IP joint of the thumb when tapping/flicking/flexing the nail of the index or ring finger may indicate an UMN lesion if asymmetrical
Pronator Drift: Unable to maintain full arm extension and supination; side of forearm pronation reflects contralateral pyramidal tract lesion; closing eyes accentuates effect

Pyramidal Pattern of Muscle Weakness (i.e. UMN)
Weaker arm extensors: shoulder abduction, elbow extension, wrist extension, finger extension, finger abduction
Weaker leg flexors: hip flexion, knee flexion, ankle dorsiflexion

Primitive Reflexes
Grasp, palmomental, root, glabellar tap, snout

Table 4. Approach to Strength Testing of Radiculopathies vs. Peripheral Neuropathies

How to use this table: For each nerve root, learn two (or more) peripheral nerves (and their associated muscles/movements). In radiculopathies, all associated peripheral nerves (and their movements) will be impaired, whereas in peripheral neuropathies, only one of the nerves (and its movement) will be impaired, sparing the other nerve. Particularly useful peripheral nerve "pairs" are bolded for emphasis.

Root	Peripheral Nerve	Movement	Muscle
C5	Axillary	Shoulder abduction	Deltoid
C6	Musculocutaneous (C5/6) Radial (C6)	Elbow flexion Elbow flexion Wrist extension	Biceps Brachioradialis Extensor carpi radialis longus
C7	Radial Posterior interosseus	Elbow extension Finger extension	Triceps Extensor digitorum communis
C8, T1	Median	Thumb flexion Thumb abduction Opposition	Flexor pollicis brevis (look for thenar wasting) Abductor pollicis brevis (look for thenar wasting) Opponens pollicis (look for thenar wasting)
	Ulnar	Finger abduction	First dorsal interosseus (look for wasting in first dorsal webbed space)
L2, 3, 4	Femoral Obturator	Hip flexion Hip adduction	Iliopsoas Adductor muscles
L3, 4	Femoral (L3/4) Deep peroneal (L4/5)	Knee extension Dorsiflexion	Quadriceps Tibialis anterior
L5	Sciatic (L5, S1) Tibial Superficial peroneal Deep peroneal	Hip extension Ankle inversion Ankle eversion Big toe extension	Gluteus maximus Tibialis posterior Peroneal muscles Extensor hallucis longus
S1	Sciatic Tibial	Knee flexion Plantar flexion	Hamstring muscles Gastrocnemius and soleus

Sensory Exam

- **primary sensation**
 - spinothalamic tract: crude touch, pain, temperature
 - dorsal column-medial lemniscus pathway: fine touch, vibration, proprioception
- **cortical sensation**
 - graphesthesia, stereognosis, extinction, 2-point discrimination

Coordination Exam and Gait

- **coordination exam**
 - finger-to-nose, heel-to-shin, knee taps, rapid alternating movements
- **stance and gait**
 - Romberg test
 - pull test or push and release test for postural instability
 - gait: antalgic, hemiplegic, ataxic, apraxic (or apraxia-like – not necessarily true apraxia), Parkinsonian gait, foot drop, broad-based
 - tandem gait (heel-to-toe test)

MRC Muscle Strength Scale

- 5 Full power
- 4 Submaximal power against resistance (ranging 4+, 4, 4-)
- 3 Full ROM against gravity without resistance
- 2 Full ROM with gravity removed
- 1 Muscle flicker
- 0 No muscle contraction

Deep Tendon Reflexes

Root	Muscle Tendon
C5/6	Biceps
C6	Brachioradialis
C7	Triceps
C8	Finger flexors
L2/3	Hip adductors
L3/4	Knee extensors
S1/2	Plantar flexion

Deep Tendon Reflex Scoring

- 0 Absent
- 1+ Depressed – elicited with reinforcement only
- 2+ Normal
- 3+ Increased
- 4+ Clonus (≥4 beats)

Interpreting a Slow or Uncoordinated Rapid Alternating Movement (RAM)

- Slow RAMs without fatiguing is suggestive of weakness (especially if it is asymmetric)
- Slow RAMs with fatiguing (i.e. decreasing amplitude over time) is suggestive of Parkinsonism
- Uncoordinated RAM is suggestive of cerebellar disorder (i.e. ataxia and irregularly irregular rhythm) or ideomotor apraxia

Common Cerebellar Findings

Frontal executive dysfunction/disinhibition, scanning speech, nystagmus, hypo- or hyper-metric saccades, hypotonia, pendular reflexes, intention tremor, ataxic finger-nose/heel-shin/tandem, wide based stance and gait, positive rebound
Midline cerebellar diseases: truncal ataxia
Lateral cerebellar hemisphere diseases: limb ataxia

Romberg Test

Stable with eyes open and closed = normal
Stable with eyes open, falls with eyes closed = positive Romberg, suggesting loss of joint position sense

Figure 4. Spinothalamic tract from body

Figure 5. Discriminative touch pathway (dorsal column) from face

Figure 6. Spinothalamic tract pathway from face

Figure 7. Corticospinal motor pathway

Figure 8. Sympathetic and parasympathetic pathway

Figure 9. Dermatome map

Myotomes

- C5 - Shoulder abduction/elbow flexion
- C6 - Wrist extensors
- C7 - Elbow extension
- C8 - Finger flexion
- T1 - Finger abduction
- T2-9 - Intercostal (abdominal reflexes)
- T9-10 - Upper abdominals
- T11-12 - Lower abdominals
- L2 - Hip flexion
- L3 - Hip adduction
- L4 - Knee extension and ankle dorsiflexion
- L5 - Ankle dorsiflexion and big toe extension
- S1 - Plantarflexion

Lumbar Puncture

Indications

- diagnostic: CNS infection (meningitis, encephalitis), inflammatory disorder (MS, Guillain-Barré, vasculitis), subarachnoid hemorrhage (if CT negative), CNS neoplasm (neoplastic meningitis)
- therapeutic: to administer anesthesia, chemotherapy, contrast media; to decrease ICP (pseudotumour cerebri, NPH)

Contraindications

- mass lesion causing increased ICP, could lead to cerebral herniation; CT first if suspect mass lesion
- infection over LP site/suspected epidural abscess
- low platelets (<50,000) or treatment with anticoagulation (high INR or aPTT)
- uncooperative patient

Complications

- tonsillar herniation (rare)
- SDH (rare)
- transient 6th nerve palsy (rare)
- post-LP headache (5-40%): worse when upright, better supine; generally onset within 24 h
 - prevention: smaller gauge (i.e. 22) needle, reinsert stylet prior to needle removal, blunt-ended needle
 - symptomatic treatment: caffeine and sodium benzoate injection
 - corrective treatment: blood patch (autologous)
- spinal epidural hematoma
- infection

LP Tubes

- **tube #1:** cell count and differential: RBCs, WBCs, and differential
 - xanthochromia (yellow bilirubin pigmentation implies recent bleed into CSF, diagnostic of SAH)
- **tube #2:** chemistry: glucose (compare to serum glucose) and protein
- **tube #3:** microbiology: Gram stain and C&S
 - specific tests depending on clinical situation/suspicion
 - ♦ viral: PCR for herpes simplex virus (HSV) and other viruses
 - ♦ bacterial: polysaccharide antigens of *H. influenzae*, *N. meningitidis*, *S. pneumoniae*
 - ♦ fungal: cryptococcal antigen, culture
 - ♦ TB: acid-fast stain, TB culture, TB PCR
- **tube #4:** cytology: for evidence of malignant cells
- **tube #5:** cell count: compare RBC count to that of tube #1
 - note: tube 4 or 5 can be sent for repeat cell count

The needle for a LP is inserted into one of L3-4, L4-5, or L5-S1 interspaces

Do not delay antibiotics while waiting for a LP if infection is suspected

RBCs in tube #1 >> #5 → traumatic tap
RBCs in tube #1 = #5 → SAH

Table 5. Lumbar Puncture Interpretation (Normal vs. Various Infectious Causes)

Condition	Colour	Protein	Glucose	Cells
NORMAL	Clear	<0.45 g/L	60% of serum glucose or >3.0 mmol/L	0-5 x 10 ⁶ /L
Viral Infection	Clear or opalescent	Normal or slightly increased <0.45-1 g/L	Normal	<1,000 x 10 ⁶ /L Lymphocytes mostly, some PMNs
Bacterial Infection	Opalescent yellow, may clot	>1 g/L	Decreased (<25% serum glucose or <2.0 mmol/L)	>1,000 x 10 ⁶ /L PMNs
Granulomatous Infection (tuberculosis, fungal)	Clear or opalescent	Increased but usually <5 g/L	Decreased (usually <2.0-4.0 mmol/L)	<1,000 x 10 ⁶ /L Lymphocytes

Approach to Common Presentations

Weakness

Approach

- **mode of onset:** abrupt (vascular, toxic, metabolic), subacute (neoplastic, infective, inflammatory), insidious (hereditary, degenerative, endocrine, neoplastic)
- **course:** worse at onset (vascular), progressive (neoplastic, degenerative, infective), episodic (vascular, inflammatory), activity dependent (NMJ, muscular)
- **pattern:** objective vs. subjective, generalized vs. localized, asymmetric vs. symmetric, proximal vs. distal, UMN vs. LMN, peripheral vs. myotomal
- **associated symptoms:** sensory, cortical, autonomic, spinal (i.e. bowel/bladder dysfunction), signs/symptoms specific to various etiologies
- **history:** family history, developmental history, medications, risk factors, recent/preceding exposures
- **investigations for LMN:** NCS/EMG
- **investigations for UMN:** imaging (brain and/or spinal cord)

Differential Diagnosis

- objective muscle weakness; also, differentiate between true muscle weakness vs. fatigue
 - generalized
 - ♦ myopathy (proximal > distal weakness)
 - endocrine: hypothyroidism, hyperthyroidism, Cushing's syndrome
 - rheumatologic: polymyositis, vasculitis
 - infectious: HIV, CMV, influenza
 - other: collagen vascular disorders, steroids, statins, alcohol, electrolyte disorders
 - ♦ NMJ (MG, botulism, LEMS, organophosphate poisoning)
 - ♦ cachexia
 - localized
 - ♦ UMN (vasculitis, abscess, brain tumour, vitamin B12 deficiency, MS, stroke)
 - ♦ radicular pain (i.e. nerve root)
 - ♦ anterior horn cell (spinal muscular atrophy, ALS, polio, paraneoplastic, lead toxicity)
 - ♦ peripheral neuropathy (peroneal muscle atrophy, GBS, leprosy, amyloid, myeloma, DM, lead toxicity)
- no objective muscle weakness
 - chronic illness (cardiac, pulmonary, anemia, infection, malignancy)
 - depression, deconditioning

Numbness/Altered Sensation

Approach

- positive sensory symptoms: paresthesia/dysesthesia = tingling, pins and needles, prickling, burning, stabbing
- negative sensory symptoms: hypoesthesia/anesthesia = numbness, reduction/absence of feeling
- determine distribution of sensory loss:
 - nerve root vs. peripheral nerve
 - symmetric stocking-glove pattern (indicative of distal symmetric polyneuropathy)
 - dissociated sensory loss: dorsal column (fine touch, proprioception, vibration) vs. spinothalamic tract (pain and temperature)
- investigations: NCS, blood glucose, vitamin B12 levels, imaging based on associated findings

Differential Diagnosis

- cerebral: stroke, demyelination, tumour
 - associated symptoms: hemiplegia, aphasia, apraxia
- brainstem: stroke, demyelination, tumour
 - associated symptoms: diplopia, vertigo, dysarthria, dysphagia
- spinal cord/radiculopathy: cord infarction, tumour, MS, syringomyelia, vitamin B12 deficiency, disc lesion
 - associated symptoms: back/neck pain, weakness (paraparesis or Brown-Séquard pattern)
- neuropathy: focal compressive neuropathy (based on location and distribution), DM, uremia, vasculitis, vitamin B12 deficiency, HIV, Lyme disease, alcohol, paraneoplastic, amyloid

Gait Disturbance

Approach

1. **Characterization of the gait disturbance**
 - posture, stride length, width between feet, height of step, stability of pelvis, symmetry, arm swing, difficulty turning, tremor, elaborate/inconsistent movements, standing from sitting
2. **Identification of accompanying neurologic signs**
 - full neurological exam required (diagnosis often can be made by P/E alone)
3. **Identify red flags**
 - sudden onset, cerebellar ataxia, paresis (hemi-, para- or quadri-), bowel/bladder incontinence
4. **Workup**
 - based on etiology – requires blood work, neuroimaging, and urgent neurologist referral

Central Motor Systems

3 components to the control of gait:

- Pyramidal: main outflow from cortex to spinal cord
- Extrapyrmidal: basal ganglia inhibits excess movements
- Cerebellum: affects coordination of gait

Table 6. Types of Gait Disturbance

Location	Description	Disorder
Visual Loss	Broad based gait with tentative steps	Cataract surgery without lens replacement
Proprioceptive Loss	Sensory ataxia: wide-based with high stepping posture and positive Romberg	Demyelinating neuropathies, paraneoplastic syndrome, tabes dorsalis, MS, compressive myelopathy, B12 deficiency
Peripheral Vestibular Lesion 1. Acute 2. Bilateral	1. Vestibular ataxia 2. Disequilibrium	1. Tumour, trauma, infectious, Ménière's disease 2. Ototoxic drugs
Peripheral Nerve Disorder 1. Foot drop 2. Lumbosacral radiculopathy	Steppage gait	Acquired/hereditary peripheral neuropathy, compressive peroneal neuropathy, L4-5 radiculopathy
Myopathies	Waddling gait: broad based, short stepped gait with pronounced lumbar lordosis, rotation of pelvis	Progressive muscular dystrophy
Pyramidal/Corticospinal Tract Lesion 1. Unilateral 2. Bilateral	Spastic gait: spastic foot drop, circumduction, scissoring of legs or toe walking with bilateral circumduction	Unilateral: stroke (ischemic/hemorrhagic) Bilateral: cervical spondylosis, cerebral palsy, spinal cord tumour, combined spinal cord degeneration, MS, motor neuron disease
Basal Ganglia	1. Parkinsonian gait: small paces, stooped posture, reduced armswing 2. Choreic/hemiballistic/dystonic gait	Infarct, Huntington's, Sydenham's chorea, Wilson's disease, SLE, neuroleptic medications, polycythemia vera, genetic dystonia
Cerebellar Disorder	Cerebellar ataxic gait: wide-based without high stepping; veers to side of lesion Alcoholic gait	Primary and secondary neoplasm, toxins (alcohol), vitamin E deficiency, hypothyroid, hypoxia, hypoglycemia, paraneoplastic syndrome

Cranial Nerve Deficits

CN I: Olfactory Nerve

Clinical Features

- anosmia associated with a loss of taste

Differential Diagnosis

- nasal:** physical obstruction
 - heavy smoking, chronic rhinitis, sinusitis, neoplasms, septal deformity, choanal atresia, vestibular stenosis, foreign body
- olfactory neuroepithelial:** destruction of receptors or their axon filaments
 - influenza, herpes simplex, interferon treatment of hepatitis C virus, atrophic rhinitis (leprosy)
- central:** lesion of olfactory pathway
 - Kallmann syndrome, albinism, head injury, cranial surgery, SAH, chronic meningeal inflammation, meningioma, aneurysm, PD, stroke, MS
- endocrine/metabolic**
 - DM, adrenal hypo/hyperfunction, pseudohypoparathyroidism, hypothyroidism, renal/liver failure, vitamin deficiency

CN II: Optic Nerve

- see *Neuro-Ophthalmology*, N14

CN III: Oculomotor Nerve

Clinical Features

- ptosis, resting eye position is "down and out" (depressed and abducted), pupil dilated (mydriasis)
- vertical and horizontal diplopia; paralysis of adduction, elevation, and depression

Differential Diagnosis

- PComm aneurysm:** early mydriasis, then CN III palsy
- cavernous sinus** (internal carotid aneurysm, meningioma, sinus thrombosis): associated with deficits in other CNs near the cavernous sinus
- midbrain lesion:** complete unilateral CN III palsy with bilateral weakness of the superior rectus and ptosis with contralateral pyramidal signs \pm mydriasis
- orbital lesion:** associated with optic neuropathy, chemosis, proptosis
- other:** inflammatory, infection, neoplasia, uncal herniation, trauma

If anosmia is not associated with loss of taste, consider malingering

Figure 10. Diagnostic positions of gaze to isolate primary action of each muscle

Kallmann syndrome is a congenital disorder of anosmia and hypogonadotropic hypogonadism

Pupillary constrictor fibres run along outside of nerve, whereas vasculature is contained within nerve
For CN III palsy with a reactive pupil, always think ischemic cause ("pupil sparing")
For CN III palsy with mydriasis, think compressive lesion

Lesions involving the cavernous sinus can lead to cranial nerve palsies of III, IV, VI, V1, and V2 as well as orbital pain and proptosis

Figure 11. Cavernous sinus (coronal view)

DDx of CN III Palsy

- iCAM
- ischemic
- Cavernous sinus
- Aneurysm (PComm, internal carotid)
- Midbrain lesion

CN IV is the only cranial nerve that decussates at midline and exits posteriorly
A CN IV lesion may cause a contralateral deficit if lesion affects the nucleus

CN IV is at risk of trauma during neurosurgical procedures involving the midbrain because of its long intracranial course

Distinguishing CN III, IV, and VI Lesions

	III	IV	VI
Diplopia	Oblique	Vertical	Horizontal
Exacerbating	Near target	Looking down	Far target
Head Tilt	Up and rotated away	Down and flexed away	Rotated towards

Jaw deviation is towards the side of a LMN CN V lesion

CN VI has the longest intracranial course and is vulnerable to increased ICP, creating a false localizing sign

Forehead is spared in a UMN CN VII lesion due to bilateral innervation of CN VII nuclei from cerebral hemispheres for the frontalis

When screening for dysphagia and assessing aspiration risk, the presence of a gag reflex is insufficient; the correct screening test is to observe the patient drinking water from a cup while observing for any coughing, choking, or "wetness" of voice

CN IV: Trochlear Nerve

Clinical Features

- vertical and torsional diplopia; defect of intorsion and depression
- patient may complain of difficulty going down stairs or reading

Differential Diagnosis

- common: ischemic (DM, HTN), idiopathic, trauma (TBI or surgical), congenital
- other: cavernous sinus lesion, superior orbital fissure (tumour, granuloma)

CN V: Trigeminal Nerve

Clinical Features

- ipsilateral loss of facial sensation and corneal reflex, weakness of muscles of mastication (V3 only) with pterygoid deviation towards the side of the lesion

Differential Diagnosis

- **brainstem:** ischemia, tumour, syringobulbia, demyelination
- **peripheral:** tumour, aneurysm, chronic meningitis, metastatic infiltration of nerve
- **trigeminal ganglion:** acoustic neuroma, meningioma, fracture of middle fossa
- **cavernous sinus:** carotid aneurysm, meningioma, sinus thrombosis
- **trauma**
- note: other CN V lesions that cause facial pain = trigeminal neuralgia, herpes zoster

CN VI: Abducens Nerve

Clinical Features

- resting inward deviation (esotropia)
- horizontal diplopia; defect of lateral gaze

Differential Diagnosis

- **pons** (infarction, hemorrhage, demyelination, tumour): associated with facial weakness and contralateral pyramidal signs
- **tentorial orifice** (compression, meningioma, trauma): false localizing sign of increased ICP
- **cavernous sinus:** carotid aneurysm, meningioma, sinus thrombosis
- **ischemia of CN VI:** DM, temporal arteritis, HTN, atherosclerosis
- **congenital:** Duane's syndrome

CN VII: Facial Nerve

Clinical Features

- **LMN lesion:** ipsilateral facial weakness (facial droop, flattening of forehead, inability to close eyes, flattening of nasolabial fold)
- **UMN lesion:** contralateral facial weakness with forehead sparing (due to bilateral frontalis innervation)
- impaired lacrimation, decreased salivation, numbness behind auricle, hyperacusis, taste dysfunction of anterior 2/3 of tongue

Differential Diagnosis

- **idiopathic** = Bell's palsy, 80-90% of cases (see **Otolaryngology, OT22**)
 - most often related to HSV, but other viruses may be implicated (CMV, herpes zoster, EBV)
- **other:** temporal bone fracture, EBV, Ramsay Hunt (VZV), otitis media/mastoiditis, sarcoidosis, DM mononeuropathy, parotid gland disease, Lyme meningitis, HIV

Figure 12. UMN vs. LMN facial nerve palsy

Facial Nerve Branch Memory Aid To Zanzibar By Motor Car
 Temporal
 Zygomatic
 Buccal
 Mandibular
 Cervical

Differential Diagnosis of Lower Cranial Nerve Deficits (CN IX, X, XI, XII)
Intracranial/Skull Base: meningioma, neurofibroma, metastases, osteomyelitis, meningitis
Brainstem: stroke, demyelination, syringobulbia, poliomyelitis, astrocytoma
Neck: trauma, surgery, tumours

Normal swallowing is initiated when the tongue moves a bolus back into the palatal archway. Tongue movements are innervated exclusively by CN XII. The bolus stimulates the soft palate to elevate and the bolus is deflected into the oropharynx. Next the pharyngeal constrictors contract, the larynx elevates, and the vocal cords close. Swallowing depends on afferent information via CN V, IX, and X and motor action via CN V, VII, IX, X, and XII. Connections in the nucleus of the tractus solitarius in the medulla (in proximity to the respiratory centre) act as the swallowing centre. Swallowing and breathing are coordinated to prevent aspiration

© N. Burachynsky 2012

CN VIII: Vestibulocochlear Nerve

- see [Otolaryngology, OT14](#)

CN IX: Glossopharyngeal Nerve

Clinical Features

- unilateral lesion is rare
- taste dysfunction in posterior 1/3 of tongue
- absent gag reflex and dysphagia

Disorders

- glossopharyngeal neuralgia: sharp paroxysmal pain of posterior pharynx radiating to ear, triggered by swallowing
 - treated with carbamazepine or surgical ablation of CN IX

CN X: Vagus Nerve

Clinical Features

- oropharyngeal dysphagia (transfer dysphagia) due to palatal and pharyngeal weakness
 - neuromuscular causes of dysphagia
 - ♦ CNS: stroke, cerebral palsy, tumour, trauma, PD, AD, MS
 - ♦ CN: DM, laryngeal nerve palsy, polio, ALS
 - ♦ myopathic/NMJ: dermatomyositis, polymyositis, MG, sarcoidosis
 - other causes of dysphagia: see [Gastroenterology, G8](#)
- dysarthria: inability to produce understandable speech due to impaired phonation and/or resonance

Uvula deviation is away from the side of a LMN CN X lesion due to impaired ipsilateral palatal elevation

CN XI is vulnerable to damage during neck surgery

CN XI: Accessory Nerve

Clinical Features

- **LMN lesion:** paralysis of ipsilateral trapezius and sternocleidomastoid (ipsilateral shoulder drop, weakness on turning head to contralateral side)
- **UMN lesion:** paralysis of ipsilateral sternocleidomastoid and contralateral trapezius

CN XII: Hypoglossal Nerve

Clinical Features

- **LMN lesion:** tongue deviation towards lesion; ipsilateral tongue atrophy and fasciculations (if chronic)
- **UMN lesion:** tongue deviation away from lesion; absence of atrophy and fasciculations

Neuro-Ophthalmology

Optic Neuritis

- see *Optic Disc Edema, Multiple Sclerosis, N52*

Anterior Ischemic Optic Neuropathy (AION)

- see *Optic Disc Edema*
- non-arteritic (NAION): due to atherosclerosis
- arteritic (AAION): due to giant cell arteritis (see *Rheumatology, RH20*)

NAION can be caused by use of sildenafil (Viagra®) in rare cases

Amaurosis Fugax

- see *Ophthalmology, OP35 and Stroke, N48*

Optic Disc Edema

Table 7. Common Causes of Optic Disc Edema

	Optic Neuritis	Papilledema	AION	CRVO
Age	<50 yr	Any	>50 yr but usually >70 yr	>50 yr
Vision	Rapidly progressive monocular central vision loss (↓ acuity and colour vision) with recovery	Late visual loss	Painless unilateral acute field defect over hours to days with ↓ colour vision	Painless unilateral variable vision loss
Symptoms	Pain (especially with eye movement)	H/A, N/V, local neurological deficits	If GCA: H/A, scalp tenderness, jaw claudication, weight loss, fatigue	Cardiovascular risk factors
Pupil	RAPD	No RAPD	RAPD	± RAPD
Fundus	Disc swelling if anterior Normal disc if retrobulbar	Bilateral disc swelling, retinal hemorrhage, no venous pulsations	Pale segmental disc edema, retinal dot, flame hemorrhages	Swollen disc, venous engorgement, retinal hemorrhage
Etiologies	MS, viral	Increased ICP	Giant cell arteritis Non-arteritic: atherosclerosis	Associated with vasculopathy, thrombus
Investigations	MRI with gadolinium	Emergent CT; LP if CT is normal to measure opening pressure	CBC, ESR, CRP, temporal artery biopsy	Fluorescein angiogram and coherence tomography
Treatment	IV methylprednisolone	Treat cause	Consider ASA if non-arteritic; steroids if arteritic	Optimize risk factors, reduce IOP, ± laser, ± VEGF inhibitors

If you suspect the diagnosis of giant cell arteritis do not wait for biopsy results, begin treatment immediately

Optic Disc Atrophy

- **etiologies:** glaucoma, AION, compressive tumour, optic neuritis, Leber's hereditary optic neuropathy, congenital
- **presentation:** disc pallor, low visual acuity, peripheral vision defect, decreased colour vision
- **treatment:** none (irreversible), aim to prevent

Abnormalities of Visual Field

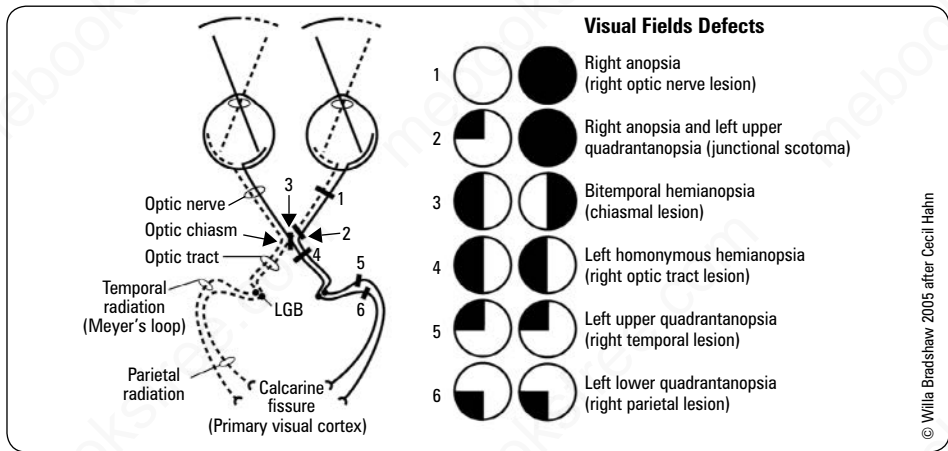

Figure 13. Characteristic visual field defects with lesions along the visual pathway

Abnormalities of Eye Movements

Disorders of Gaze

Pathophysiology

- horizontal gaze: FEF → contralateral PPRF (midbrain/pons) → eyes saccade away from FEF
- vertical gaze: cortex → rostral interstitial nucleus in the MLF (midbrain)

Clinical Features

- unilateral lesion in one FEF → eyes deviate toward the side of the lesion
 - can be overcome with doll's eye maneuver
- unilateral lesion in the PPRF → eyes deviate away from the lesion
 - cannot be overcome with doll's eye maneuver if CN VI nucleus lesion as well
- seizure involving a FEF: eyes deviate away from the focus

Etiology

- common: infarcts (frontal or brainstem), MS, tumours

Internuclear Ophthalmoplegia

Pathophysiology

- results from a lesion in MLF which disrupts coordination between CN VI nucleus in pons and the contralateral CN III nucleus in midbrain → disrupts conjugate horizontal gaze

Clinical Features

- horizontal diplopia on lateral gaze, oscillopsia
- gaze away from the side of the lesion: ipsilateral adduction defect and contralateral abduction nystagmus
- cannot be overcome by caloric testing
- accommodation reflex intact
- may be bilateral (especially in MS)

Etiology

- common: MS, brainstem infarct

Investigations

- MRI

Bitemporal Hemianopsia DDx by Age

- Children: craniopharyngioma
- Middle aged (20s to 50s): pituitary mass
- Elderly (>60 yr): meningioma

In homonymous hemianopsia, more congruent deficits are caused by more posterior lesions; macular sparing may occur with occipital lesions

A lesion in a cerebral hemisphere causes eyes to "look away" from the hemiplegia, and to look towards the lesion

A lesion in the brainstem causes the eyes to "look toward" the side of the hemiplegia, and to look away from the lesion

Check all hemiplegic patients for homonymous hemianopsia (ipsilateral to side of hemiplegia)

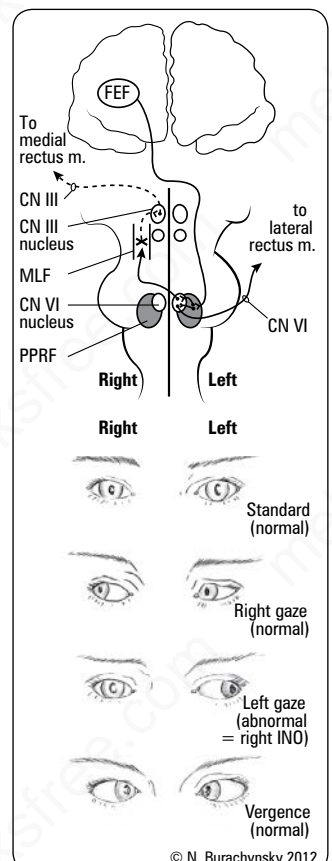

Figure 14. Internuclear ophthalmoplegia

Diplopia

Etiology – Monocular

- mostly due to relatively benign optical problems (refractive error, cataract) or functional

Etiology – Binocular (due to ocular misalignment)

- muscle: Graves' ophthalmopathy, EOM restriction/entrapment
- neuromuscular junction: MG (see *Myasthenia Gravis*, N38)
- cranial nerve palsy (see *Cranial Nerve Deficits*, N11)
- INO (see *Internuclear Ophthalmoplegia*, N15)
- other
 - orbital trauma (orbital floor fracture), tumour, infection, inflammation
 - Miller-Fisher variant of GBS
 - Wernicke's encephalopathy
 - leptomeningeal disease

Approach to Diplopia

- monocular (diplopia when one eye open) vs. binocular (diplopia when both eyes open)
- horizontal vs. vertical vs. oblique diplopia
- direction of gaze that exacerbates diplopia
- corrective head movements

Workup

- may observe isolated 4th or 6th nerve palsy for a few weeks, but workup if persistent or other symptoms develop
- indications for neuroimaging
 - bilateral or multiple nerve involvement
 - severe sudden onset headache (rule out aneurysm)

Nystagmus

- **definition:** rapid, involuntary, small amplitude movements of the eyes that are rhythmic in nature
- direction of nystagmus is labelled by the rapid component of the eye movement
- can be categorized by movement type (pendular, jerking, rotatory, coarse) or as physiological vs. pathological

Table 8. Nystagmus Features

	Peripheral (Vestibular)	Central (Brainstem)
Direction	Unidirectional, fast phase away from the lesion	May be bilateral/unidirectional
Nystagmus	Usually horizontal	Usually vertical
Gaze Fixation	Relieves nystagmus	Does not relieve nystagmus
Vertigo	Severe	Mild
Auditory Symptoms	Common	Extremely rare
Other Neurological Signs	Absent	Often present
DDx	Benign paroxysmal positional vertigo, vestibular neuritis, Ménière's disease, toxicity, trauma, Ramsay Hunt syndrome	MS, vascular (brainstem/cerebellar), neoplastic/paraneoplastic

Abnormalities of Pupils

- see *Ophthalmology*, OP28

Diplopia worse at the end of the day suggests myasthenia gravis (e.g. fatigable)

If diplopia is only on extremes of gaze, cover each eye in isolation during extremes of gaze. The covered eye that makes the lateral image disappear is the pathological one

Left CN III (complete)
Eye position down and out (with ptosis and pupillary dilation)

Left Sympathetic Pathway
Horner's syndrome: ptosis, miosis, and anhidrosis

CN IV
Difficulty looking down and in (i.e. looking down at a golf ball – think CN Fore!)

Left CN VI
Difficulty looking laterally

Left Medial Longitudinal Fasciculus
Internuclear ophthalmoplegia (INO): Difficulty adducting ipsilateral eye and horizontal nystagmus in abducted contralateral eye

© Minyan Wang 2012

Figure 15. Abnormal eye movement

Nutritional Deficiencies and Toxic Injuries

- sufficient nutritional intake is required for optimal nervous system functioning; deficiencies in the following key nutrients, among others, may impair central and peripheral nervous system function (potential neurological symptoms are provided)

Table 9. Nutritional Deficiency Features and Management

Vitamin Deficiency	Neurological Clinical Manifestation	Investigation	Treatment*
Vitamin B12	Paresthesias and sensory ataxia are the most common initial symptoms Myelopathy (Subacute Combined Degeneration), peripheral neuropathy Neuropsychiatric: memory impairment, change in personality, delirium, and psychosis Optic neuropathy	Serum cobalamin Serum methylmalonic acid Serum homocysteine	IM Vitamin B12 1,000 µg for 5 d, then once per month or oral B12 1,000 µg/d
Folate	Myelopathy, peripheral neuropathy May be clinically indistinguishable from Vitamin B12 deficiency	Serum folate Homocysteine	Oral folate 1 mg tid initially; 1 mg daily thereafter
Copper	Myelopathy, pyramidal signs (e.g. brisk muscle stretch reflexes at the knees and extensor plantar responses) Severe sensory loss	Serum copper and ceruloplasmin; urinary copper	Discontinue zinc; oral copper 8 mg/d for 1 wk; 6 mg/d for 1 wk; 4 mg/d for 1 wk; 2 mg/d thereafter
Vitamin E	Ophthalmoplegia, retinopathy, spinocerebellar syndrome with peripheral neuropathy (with signs of cerebellar ataxia)	Serum vitamin E; ratio serum vitamin E to sum of cholesterol and triglycerides	Vitamin E 2,200 mg/kg/d oral or IM
Thiamine	Three manifestations include: beriberi (dry and wet), infantile beriberi, Wernicke-Korsakoff syndrome Alcoholism is a cause of reduced thiamine intake and deficiency	Clinical diagnosis; brain MRI	Thiamine 100 mg IV followed by 50-100 mg IV or IM until nutritional status stable
Pyridoxine (Vitamin B6)	Painful sensorimotor peripheral neuropathy	Serum pyridoxal phosphate	Pyridoxine 50-100 mg daily
Niacin (Vitamin B3)	Pellagra: Encephalopathy, dementia, coma, and peripheral neuropathy	Urinary excretion niacin metabolites	Nicotinic acid 25-50 mg daily oral or IM

*IM = intramuscular; IV = intravenous

- it is also important to consider occupational neurotoxic syndromes secondary to exposure to pesticides, solvents, and metals. Encephalopathy, extrapyramidal features, neurodegenerative diseases, and peripheral neuropathy are commonly encountered. Onset and progression of neurological diseases should be temporally related to neurotoxin exposure. Main toxins associated with neurotoxicity are listed below

Table 10. Selected Occupational Neurotoxic Syndromes

Toxin	Associated Occupations	Characteristic Neurological Findings
Organic Solvents	Printer, spray painters, industrial cleaners, paint or glue manufacturers, graphic industry, electronic industry, plastic industry	Nausea, H/A, concentration difficulty Long-term exposure may lead to "chronic solvent-induced encephalopathy", characterized by mild-to-severe cognitive impairment
Pesticides (e.g. insecticides, fungicides, rodenticides, fumigants, herbicides)	Agricultural work, pesticide manufacturing and formulating employees, highway and railway workers, green house, forestry and nursery workers	Parkinson's disease risk increased by ~70% following pesticide exposure
Heavy Metals (e.g. lead, mercury, manganese, aluminum, arsenic)	Battery and metal production (e.g. solder, pipes), chemical and electronic application industries, steel manufacturing, welders, alloy workers, transportation, packaging, construction	Lead: delayed/reversed development, permanent learning disabilities, peripheral neuropathy, seizures, coma, death from encephalopathy (rare) Mercury: psychiatric disturbances, ataxia, visual loss, hearing loss, tiredness, memory disturbances Manganese: psychiatric symptoms, hallucinations ("manganese madness"), extrapyramidal features, dystonia, parkinsonism (manganism) Aluminum: implicated in Alzheimer's pathogenesis Arsenic: sleeplessness/sleepiness, irritability, H/A, spasms in muscle extremities and muscle fatigue
Gases (e.g. carbon dioxide, nitrous oxide, formaldehyde)	Anesthesia, disinfection, manufacture of illuminating gas and water-gas	Cognitive/behavioural and emotional symptoms, parkinsonian syndromes

Neurologic Complications due to Toxic Injuries Related to Bariatric Surgery

- deficiencies of both fat- and water-soluble vitamins may occur following malabsorptive bariatric surgery
- patients who have undergone malabsorptive surgery should be monitored for late metabolic complications and neurological manifestations

Seizure Disorders and Epilepsy

Seizure

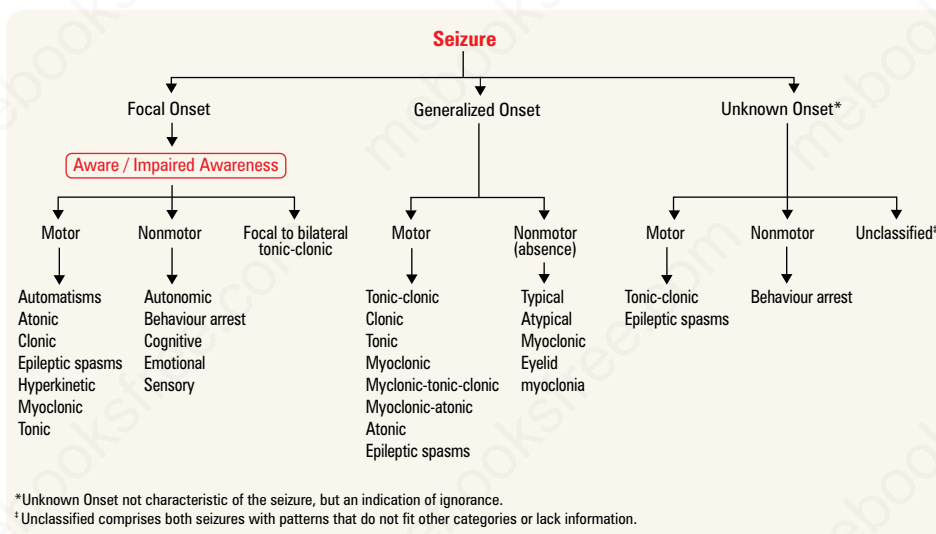

Definitions

- **seizure:** transient occurrence of signs and/or symptoms due to abnormal excessive or synchronous neuronal brain activity
 - can be symptom of acute insult to the brain such as: alcohol and illicit drug use/withdrawal, brain injury/abnormality (tumour, trauma, vascular), CNS infection, fever (children), metabolic (hypoglycemia, electrolyte abnormalities, liver/renal failure), medications, or be a manifestation of epilepsy
- **epilepsy:** disorder of the brain characterized by an enduring predisposition to generate epileptic seizures, and by the neurobiologic, cognitive, psychological, and social consequences of this condition. The definition of epilepsy requires the occurrence of at least one epileptic seizure
 - etiologies: genetic, structural (e.g. prior stroke, tumour, meningo/encephalitis, perinatal insult, vascular malformation, malformation of cortical development, neurodegenerative), or unknown

Stroke is the most common cause of late-onset (>50 yr) seizures, accounting for 50-80% of cases

Classification

Seizures and Dementia
Neurodegenerative diseases can underlie seizures; conversely, seizures can be a cause of dementia

Figure 16. Classification of seizures

Clinical Features

- **focal (partial) seizures**
 - focal can secondarily generalize, or focal (simple) → focal with impaired awareness (complex) → generalized seizures
 - **focal with intact awareness (simple partial)**
 - ♦ motor: postural, phonatory, forceful turning of eyes and/or head, focal muscle rigidity/jerking ± Jacksonian march (spreading to adjacent muscle groups)
 - ♦ sensory: unusual sensations affecting vision, hearing, smell, taste, or touch
 - ♦ autonomic: epigastric discomfort, pallor, sweating, flushing, piloerection, pupillary dilatation
 - ♦ psychiatric: symptoms rarely occur without impairment of consciousness and are more commonly complex partial
 - **focal with impaired awareness (complex partial)**
 - ♦ patient may appear to be awake but with impairment of awareness
 - ♦ classic complex seizure is characterized by automatisms such as chewing, swallowing, lip-smacking, scratching, fumbling, running, disrobing, and other stereotypic movements
 - ♦ other forms: dysphasic, dysmnestic (déjà vu), cognitive (disorientation of time sense), affective (fear, anger), illusions, structured hallucinations (music, scenes, taste, smells), epigastric fullness
- **generalized seizures**
 - **absence (petit mal):** usually seen in children, unresponsive for 5-10 s with arrest of activity, staring, blinking or eye-rolling, no post-ictal confusion; 3 Hz spike and slow wave activity on EEG
 - **clonic:** repetitive rhythmic jerking movements
 - **tonic:** muscle rigidity in flexion or extension
 - **tonic-clonic (grand mal)**
 - ♦ may have prodrome of unease or irritability hours to days before the episode (aura)
 - ♦ tonic ictal phase: muscle rigidity
 - ♦ clonic ictal phase: repetitive violent jerking of face and limbs, tongue biting, cyanosis, frothing, incontinence
 - ♦ post-ictal phase: flaccid limbs, extensor plantar reflexes, headache, confusion, aching muscles, sore tongue, amnesia, elevated serum CK lasting hours; may have focal paralysis (Todd's paralysis)
 - **myoclonic:** sporadic contractions localized to muscle groups of one or more extremities
 - **atonic:** loss of muscle tone leading to drop attack

Temporal lobe epilepsy is suggested by an aura of fear, olfactory or gustatory hallucinations, and visceral or déjà vu sensations
Frontoparietal cortex seizures are suggested by contralateral focal sensory or motor phenomena

Table 11. Classic Factors Differentiating Seizure, Syncope and Pseudoseizure

Characteristic	Seizure	Syncope	Pseudoseizure* (Psychogenic non-epileptic seizure)
Timing	Day or night	Day	Day; other people present
Onset	Sudden, in any position	Gradual; Upright position (not recumbent)	Provoked by emotional disturbance or suggestion
Prodrome	Possible specific aura	Lightheadedness, pallor, diaphoresis	Variable
Duration	Brief or prolonged	Brief	Often prolonged
Incontinence	Common	Possible but rare	Rare
Post-ictal	Occurs in tonic-clonic or complex partial	No	Variable, often none
Motor Activity	Synchronous, stereotypic, automatisms (common in absence and complex partial), lateral tongue biting, eyes rolled back	Occasional brief jerks	Opisthotonos, rigidity, eye closure, irregular extremity movements, shaking head, pelvic thrust, crying, geotropic eye movements, tongue biting at the tip
Injury	Common	Rare unless from fall	Rare
EEG	Usually abnormal; \pm interictal discharges	Normal	Normal

*Pseudoseizures do not rule out seizures (not uncommon to have both)

- alcoholic withdrawal seizures may occur up to 2 days from the last exposure to alcohol (see [Emergency Medicine, ER54](#))

Investigations

- CBC, electrolytes, fasting blood glucose, Ca^{2+} , Mg^{2+} , ESR, Cr, liver enzymes, CK, prolactin
- also consider toxicology screen, EtOH level, AED level (if applicable)
- CT/MRI (if new seizure without identified cause or known seizure history with new neurologic signs/symptoms)
- LP (if fever or meningismus)
- EEG

Treatment

- avoid precipitating factors
- indications for antiepileptic drugs (AED): EEG with epileptiform activity, remote symptomatic cause (organic brain disease, prior head injury or CNS infection), abnormal neurologic examination or findings on neuroimaging, nocturnal seizure
- psychosocial issues: stigma of seizures, education of patient and family, status of driver's license, pregnancy issues
- safety issues: driving, operating heavy machinery, bathing, swimming alone
- refer for evaluation for possible surgical treatment if focal and refractory

Status Epilepticus

- definition:** unremitting seizure or successive seizures without return to a baseline state of greater than 5 min
- complications:** anoxia, cerebral ischemia and cerebral edema, MI, arrhythmias, cardiac arrest, rhabdomyolysis and renal failure, aspiration pneumonia/pneumonitis, death (20%)
- initial measures:** ABCs, vitals, monitors, capillary glucose (STAT), ECG, nasal O_2 , IV NS, IV glucose, IV thiamine, ABGs (if respiratory distress/cyanotic)
- blood work:** electrolytes, Ca^{2+} , Mg^{2+} , PO_4^{3-} , glucose, CBC, toxicology screen, EtOH level, AED levels
- focused history:** onset, past history of seizures, drug and alcohol ingestion, past medical history, associated symptoms, witnesses/collateral history
- physical exam** (once seizures controlled): LOC, vitals, HEENT (nuchal rigidity, head trauma, tongue biting, papilledema), complete neurological exam, signs of neurocutaneous disorders, decreased breath sounds, cardiac murmurs or arrhythmias, urinary incontinence, MSK exam (rule out injuries)
- post-treatment stabilization:** CT head, EEG, Foley catheter to monitor urine output, urine toxicology screen, monitor for rhabdomyolysis, and IV fluids to maintain normal cerebral perfusion pressure

Antiepileptic Drugs

- focal and most generalized seizures**
 - valproate (Depakene[®]), lamotrigine (Lamictal[®]), levetiracetam (Keppra[®]), topiramate (Topamax[®]), phenobarbital (Phenobarb[®]), primidone, zonisamide, rufinamide (Banzel[®]), felbamate, benzodiazepines
- primarily focal seizures (\pm 2^o generalization)**
 - carbamazepine (Tegretol[®]), phenytoin (Dilantin[®]), gabapentin (Neurontin[®]), lacosamide (Vimpat[®]), oxcarbazepine (Trileptal[®]), eslicarbazepine acetate (Aptiom[®]), pregabalin (Lyrica[®]), tiagabine (Gabitril[®]), vigabatrin (Sabril[®])
- absence seizure:** ethosuximide (Zarontin[®])

DDx of Convulsions

Syncope, pseudoseizure, hyperventilation, panic disorder, TIA, hypoglycemia, movement disorder, alcoholic blackouts, migraines (confusional, vertebrobasilar), narcolepsy (cataplexy)

Note that frontal seizures (rare) can look like a pseudoseizure due to odd motor activity that may occur

By law, the Ministry of Transportation in most provinces must be contacted for all patients who have had a seizure; patients will have their license suspended until seizure free for 6 mo; commercial drivers face a longer wait

EEG findings suggestive of epilepsy: abnormal spikes, polyspike discharges, spike-wave complexes

20-59% of first EEG are positive in epilepsy; 59-92% of epilepsy is picked up with repeated EEGs; normal interictal EEGs do not rule out epilepsy

Medical Emergency: Status epilepticus can cause irreversible brain damage without treatment

The most common causes of status epilepticus are failure to take AEDs and first presentation of epilepsy
Status epilepticus as a result of EtOH withdrawal is rare, despite it being a very common cause of seizures

Rule out non-convulsive status epilepticus in any patient who is still unconscious >20 min post-ictal; order a stat EEG if unsure

Complex partial status epilepticus can resemble schizophrenia or psychotic depression

Teratogenicity of anticonvulsants includes neural tube defects, cleft palate, urogenital malformations, and heart defects. Advise patient planning pregnancy to take 5 mg/d of folic acid. Optimize AEDs with lowest possible dose associated with good seizure control, preferably monotherapy if possible. Risk of fetal malformations with AEDs is 2x general population; highest risk associated with valproic acid and/or 2+ concurrent AEDs. Consider pre-conception AED levels if patient is well-controlled, monthly serum levels during pregnancy, and titrate AED to maintain pre-conception serum levels. Refer to high risk OB for intrapartum fetal screening

Figure 17. Status epilepticus treatment algorithm

Behavioural Neurology

- see [Psychiatry, PS19](#)

Acute Confusional State/Delirium

Table 12. Selected Intracranial Causes of Acute Confusion

	Etiology	Key Clinical Features	Investigations
Vascular	Subarachnoid hemorrhage	Thunderclap H/A, increased ICP, meningismus	CT, LP Angiography if CT and LP negative
	Stroke/TIA	Focal neurological signs	CT
Infectious	Meningitis	Fever, H/A, nausea, photophobia, meningismus	CT, LP
	Encephalitis	Fever, H/A, ± seizure Focal neurological signs	CT, LP MRI
	Abscess	Increased ICP Focal neurological signs	CT with contrast (often ring enhancing lesion)
Traumatic	Diffuse axonal shear, epidural hematoma, SDH	Trauma Hx Increased ICP Focal neurological signs	CT MRI
Autoimmune	Acute CNS vasculitis	Skin rash, active joints	ANA, ANCA, RF MRI Angiography
	Paraneoplastic encephalitis (anti-NMDA-R)	Onset: Psychiatric features, memory loss, seizures Delayed: Movement disorder, and changes in BP, HR, and temperature	CSF (test for presence of antibodies)
Neoplastic	Mass effect/edema, hemorrhage, seizure	Increased ICP Focal neurological signs Papilledema	CT MRI
Seizure	Status epilepticus	<i>See Seizure Disorders and Epilepsy, N18</i>	EEG
Primary Psychiatric	Psychotic disorder, mood disorder, anxiety disorder	No organic signs or symptoms	No specific tests
Other	Drugs (e.g. cocaine)	Chest pain, cough with black sputum, new-onset seizure, HTN, increased ICP, dyspnea	Vital signs Serum chemistry and electrolyte analysis
	Medications (with anticholinergic side effects)	Flushing, dry skin and mucous membranes, mydriasis with loss of accommodation	Serum chemistry and electrolyte analysis
	Neuroleptic Malignant Syndrome	Antipsychotic medication use Muscle rigidity Hyperthermia Autonomic instability	Serum chemistry and electrolyte analysis

Mild Neurocognitive Disorder (Mild Cognitive Impairment)

Definition

- cognitive impairment not meeting criteria of Major Neurocognitive Disorder
- measurable deficit in at least one cognitive domain reported by patient or others without impairment in ADLs
- amnesic (precursor to AD) vs. non-amnesic

Epidemiology

- mild NCD: 2-10% at age 65 yr and 5-25% by age 85 yr

Risk Factors

- vascular: hypertension, diabetes mellitus, obesity, cardiac disease, apolipoprotein E epsilon 4 genotype

Clinical Features

- cognitive impairment
 - particularly in amnesic subtype
 - important to ascertain that memory complaints represent change from baseline
 - patients with mild NCD are often troubled by memory symptoms in comparison to patients with dementia
- neuropsychiatric symptoms
 - depression (50%), irritability, anxiety, aggression, and apathy

Investigations

- establish a baseline for follow-up
- clinical interview with patient and caregivers is the cornerstone of mild NCD evaluation
- neuropsychological testing
 - MMSE or MoCA; should not be used in isolation
 - if abnormal, follow-up in one year to monitor cognitive and functional decline
- neuroimaging
 - role uncertain
 - most advocate for a non-contrast brain CT to evaluate for structural abnormalities (CVD, SDH, NPH, or mass lesion)
- other testing
 - exclude treatable conditions and underlying psychiatric conditions

Treatment

- watch and wait
- no evidence for cholinesterase inhibitors, anti-inflammatory agents, vascular risk factor modification, exercise, cognitive interventions

Prognosis

- 10% progress to major NCD per yr
- typically progress to major NCD over a period of 2-3 yr

Major Neurocognitive Disorder (formerly Dementia)

- see [Psychiatry, PS20](#) and [Geriatric Medicine, GM4](#)

Definition

- an acquired, generalized, and (usually) progressive impairment of cognitive function associated with impairment in ADLs/iADLs (i.e. shopping, food preparation, finances, medication management)
- diagnosis of major NCD requires presence of significant cognitive decline from a previous level of performance in one or more cognitive domains (complex attention, executive function, learning and memory, language, perceptual-motor, or social cognition) based on:
 - A) concern of the individual or a knowledgeable informant AND
 - B) a substantial impairment in cognitive performance either documented by standardized neuropsychological testing, or quantified clinical assessment
- see [Psychiatry, PS20](#) for DSM-5 diagnostic criteria
- in comparison, mild NCD does not affect ADLs
 - mild NCD represents an intermediate stage between major NCD and normal aging

Epidemiology

- major NCD: 1-2% at age 65 yr and reaching as high as 30% by age 85 yr
- note
 - major NCD due to Alzheimer's disease is uncommon before age 60 yr
 - major NCD due to frontotemporal lobar degeneration has an earlier onset and represents a progressively smaller fraction of all NCDs with increasing age

Delirium is a medical emergency carrying significant risk of morbidity and mortality; it is characterized by acute onset, disorientation, fluctuating level of consciousness, poor attention, and marked psychomotor changes

Visual hallucinations more commonly indicate organic disease

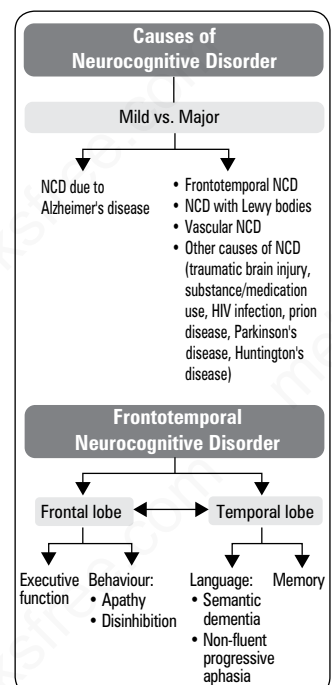

Figure 18. Major NCD classification

Etiology

- see Table 13 for selected causes of major NCD
- reversible causes: alcohol (intoxication or withdrawal, Wernicke’s encephalopathy), medication (benzodiazepines, anticholinergics), heavy metal toxicity, hepatic or renal failure, B12 deficiency, glucose, cortisol, thyroid dysfunction, normal pressure hydrocephalus (NPH), depression (pseudodementia), intracranial tumour, SDH, hypercalcemia (secondary to elevated PTH)
- must rule out delirium

History

- “geriatric giants”
 - confusion/incontinence/falls
 - memory and safety (wandering, leaving doors unlocked, leaving stove on, losing objects, driving)
 - behavioural (mood, anxiety, psychosis, suicidal ideation, personality changes, aggression)
 - polypharmacy and compliance (sedative hypnotics, antipsychotics, antidepressants, anticholinergics)
- ADLs and IADLs
- cardiovascular, endocrine, neoplastic, renal ROS, head trauma history
- alcohol, smoking
- collateral history

Physical Exam

- blood pressure
- hearing and vision
- neurological exam with attention to signs of parkinsonism, UMN findings
- general physical exam with focus on CVD, patient-specific risk factors and history
- MMSE or MoCA, clock drawing, frontal lobe testing (go/no-go, word lists, similarities, proverb)

Investigations

- rule out reversible causes
 - CBC (note MCV for evidence of alcohol use and B12 deficiency), glucose, TSH, B12, RBC folate
 - electrolytes, LFTs, renal function, lipids, serum calcium
 - CT head, MRI as indicated, SPECT (optional)
 - as clinically indicated: VDRL, HIV, ANA, anti-dsDNA, ANCA, ceruloplasmin, copper, cortisol, toxicology, heavy metals
- issues to consider
 - failure to cope, fitness to drive, caregiver capacity and wellbeing, power of attorney, legal will, advanced medical directives, patient and caregiver safety

Table 13. Selected Causes of Major NCD (Dementia)

Etiology	Key Clinical Features	Investigations
PRIMARY DEGENERATIVE		
Alzheimer’s disease	Memory impairment Aphasia, apraxia, agnosia	CT or MRI, SPECT
Dementia with Lewy bodies	Visual hallucinations Parkinsonism Fluctuating cognition	CT or MRI, SPECT
Frontotemporal dementia (e.g. Pick’s disease)	Behavioural presentation: Disinhibition, perseveration, decreased social awareness, mental rigidity, memory relatively spared Language presentation: Progressive non-fluent aphasia, semantic dementia	CT or MRI, SPECT
Huntington’s disease	Chorea	Genetic testing
VASCULAR		
Vascular cognitive impairment (previously Multi-infarct dementia)	Bradypheia without features of parkinsonism (slow thinking, slow rate of learning, slow gait) Dysexecutive syndrome May be abrupt onset Stepwise deterioration is classic but progressive deterioration is most common	CT or MRI, SPECT
CNS vasculitis	Systemic signs and symptoms of vasculitis	ANA; ANCA; RF CT or MRI Angiography

Sensitivity and Specificity

Tool	Sensitivity	Specificity
MMSE	87%	82%
Clinical Judgment	85%	82%
DSM IV	76%	80%

Vitamin B12: Deficiency Symptoms

- Macrocytic anemia, pallor, SOB, fatigue, chest pain, palpitations
- Confusion or change in mental status (if advanced)
- Decreased vibration sense
- Distal numbness and paresthesia
- Weakness with UMN findings
- Diarrhea, anorexia

Major NCD Considerations for Management

ABCDs

- Affective disorders, ADLs
- Behavioural problems
- Caretaker, Cognitive medications and stimulation
- Directives, Driving
- Sensory enhancement (glasses/hearing aids)

Most common causes of rapidly progressive neurodegenerative dementia (less than 4 yr survival): CJD, frontal temporal lobar dementia, tauopathies, diffuse Lewy body disease, and AD
Arch Neurol 2009;66:201-207
 Head turning sign: when patient looking at his/her caregiver for answers after being asked a question in clinical interviews
 60% sensitivity, 98% specificity for diagnosis of cognitive impairment

Early Signs of Major NCD

Early Signs of Major NCD	Normal Aging
Forgetting the names of close relations	Forgetting the names of acquaintances
Increased frequency of forgetting	Briefly forgetting part of an experience
Repeating phrases/stories in the same conversation	Not putting away things properly
Unpredictable mood changes	Mood changes in response to appropriate causes
Decreased interest in activities and difficulty making choices	Changes in usual interests

Table 13. Selected Causes of Major NCD (Dementia) (continued)

Etiology	Key Clinical Features	Investigations
INFECTIOUS		
Chronic meningitis	Fever, H/A, nausea Meningismus Localizing neurological deficits	CT, LP
Chronic encephalitis	Fever, headache	CT or MRI
Chronic abscess	Increased ICP Localizing neurological deficits	CT with contrast
HIV	See Infectious Diseases, ID27	HIV serology
Creutzfeldt-Jakob disease	Rapidly progressive, myoclonus	EEG, CT or MRI, LP
Syphilis	Ataxia, myoclonus, tabes dorsalis	LP, CT, or MRI VDRL
TRAUMATIC		
Diffuse axonal shear, epidural hematoma, subdural hematoma, SDH	Trauma Hx Increased ICP, papilledema Localizing neurological signs	CT
RHEUMATOLOGIC		
SLE	See Rheumatology, RH11	MRI ANA, anti-dsDNA
NEOPLASTIC		
Mass effect/edema, hemorrhage, seizure Paraneoplastic encephalitis	Increased ICP Localizing neurological signs Systemic symptoms of cancer	CT with contrast MRI Anti-Hu antibodies
OTHER		
Normal pressure hydrocephalus	Gait disturbances Urinary incontinence See Neurosurgery, NS8	CT or MRI

Cholinesterase Inhibitors for Dementia with Lewy Bodies (DLB), Parkinson's Disease Dementia (PDD) and Cognitive Impairment in Parkinson's Disease (CIND-PD)
Cochrane DB Syst Rev 2012;3:CD006504
Study: Meta-analysis of RCTs assessing efficacy of treatment with cholinesterase inhibitors in DLB, PDD, and CIND-PD.

Results: The six trials (n=1,236) included demonstrated therapeutic benefit of cholinesterase inhibitors for global assessment, cognitive function, behavioural disturbance, and activities of daily living. Cholinesterase inhibitors were associated with increased adverse events (OR 1.64) and drop out (OR 1.94). Adverse events were more common with rivastigmine but not with donepezil. Fewer deaths occurred in the treatment group (OR 0.28).

Conclusion: Current evidence supports use of cholinesterase inhibitors for patients with PDD but its role in DLB and CIND-PD is still unclear.

4 As and one D of AD
Anterograde amnesia
Aphasia
Apraxia
Agnosia
Disturbance in executive function

(Anterograde amnesia plus at least one of the other features is required for AD diagnosis)

Down syndrome predisposes to early onset of Alzheimer's (i.e. age of ~40) due to three copies of the amyloid gene (APP)

Major or Mild NCD due to Alzheimer's Disease

- see [Psychiatry, PS20](#)

Definition

- beyond criterion for NCD, the core features of Alzheimer's disease include an insidious onset and gradual progression of cognitive and behavioural symptoms
- typical presentation: amnestic
 - mild phase: impairment in memory and learning sometimes accompanied with deficits in executive function
 - moderate-severe phase: visuoconstructional/perceptual-motor ability and language may also be impaired
 - social cognition tends to be preserved until late in the course of the disease
- atypical nonamnestic presentation (one of the following):
 1. aphasia: language disturbance
 2. apraxia: impaired ability to carry out motor activities despite intact motor function
 3. agnosia: failure to recognize or identify objects despite intact sensory function

Pathophysiology

- genetic factors
 - minority (<7%) of AD cases are familial (autosomal dominant)
 - 3 major genes for autosomal dominant AD have been identified:
 - ♦ amyloid precursor protein (chromosome 21), presenilin 1 (chromosome 14), presenilin 2 (chromosome 1)
 - ♦ the E4 polymorphism of apolipoprotein E (APOE) is a susceptibility genotype (E2 is protective)
 - ♦ note: APOE cannot serve as a diagnostic marker because it is only a risk factor and neither necessary nor sufficient for disease occurrence
- pathology (although not necessarily specific for AD)
 - gross pathology
 - ♦ diffuse cortical atrophy, especially frontal, parietal, and temporal lobes (hippocampi)

- microscopic pathology
 - ♦ senile plaques (extracellular deposits of amyloid in the grey matter of the brain)
 - ♦ loss of synapses
 - ♦ neurofibrillary tangles (intracytoplasmic paired helical filaments with amyloid and hyperphosphorylated Tau protein)
 - ♦ loss of cholinergic neurons in nucleus basalis of Meynert that project diffusely throughout the cortex
- biochemical pathology
 - ♦ 50-90% reduction in action of choline acetyltransferase

Epidemiology

- 1/12 of population 65-75 yr of age
- up to 1/3 population >85 yr of age
- very rare <65 yr of age
- accounts for 60-90% of all dementias (depending on setting and diagnostic criteria)

Risk Factors

- age is the largest risk factor
- genetic susceptibility polymorphism: apolipoprotein E4 increases risk and decreases age of onset
- other factors include: traumatic brain injury, family history, Down syndrome, low education, and vascular risk factors (e.g. smoking, HTN, hypercholesterolemia, DM)

Clinical Features

- cognitive impairment
 - memory impairment for newly acquired information (early)
 - deficits in language, abstract reasoning, and executive function
- behavioural and psychiatric manifestations (80% of those with major NCD)
 - mild NCD: major depressive disorder and/or apathy
 - major NCD: psychosis, irritability, agitation, combativeness, and wandering
- motor manifestations (late)
 - gait disturbance, dysphagia, incontinence, myoclonus, and seizures

Investigations

- perform investigations to rule out other potentially reversible causes of dementia
- EEG: usually normal, may observe generalized slowing (nonspecific)
- MRI: preferential atrophy of the hippocampi and precuneus of the parietal lobe; dilatation of lateral ventricles; widening of cortical sulci
- SPECT: hypoperfusion in temporal and parietal lobes
- PET imaging using Pittsburgh compound B (PIB) as a tracer enables imaging of beta-amyloid plaque in neuronal tissue

Treatment

- acetylcholinesterase inhibitors have been shown to slow decline in cognitive function
 - Do not prolong life expectancy but improve morbidity
 - donepezil, rivastigmine, galantamine
 - relative contraindications: bradycardia, heart block, arrhythmia, CHF, CAD, asthma, COPD, ulcers, or risk factors for ulcers and/or GI bleeding
 - galantamine is contraindicated in patients with hepatic/renal impairment
- memantine is an NMDA-receptor antagonist that has some benefits in later stage AD (i.e. when MMSE <17)
- symptomatic management
 1. pharmacologic
 - ♦ low dose neuroleptics for agitation (neuroleptics may worsen cognitive decline)
 - ♦ trazodone for sleep disturbance
 - ♦ antidepressants (SSRIs)
 2. non-pharmacologic
 - ♦ redirection
 - ♦ explore inciting factors for behaviour and modify behaviour of patient or caregiver
 - ♦ family support and day care facilities

Prognosis

- mean duration of survival after diagnosis is approximately 10 yr, reflecting the advanced age of the majority of individuals rather than the course of the disease
- death commonly results from aspiration

Cognitive Effects of Atypical Antipsychotic Medications in Patients with Alzheimer's Disease: Outcomes from CATIE-AD

Am J Psychiatry 2011;168:831-839

Study: 421 outpatients with Alzheimer's disease and psychosis or agitated/aggressive behaviour were randomized to receive olanzapine, quetiapine, risperidone, or placebo in a multicentre double-blinded RCT. MMSE and Alzheimer's Disease Assessment Scale (ADAS) scores were measured at 36 wk.

Results: Patients receiving atypical antipsychotics exhibited a faster rate of cognitive decline as measured by MMSE scores (-0.067/wk vs. -0.007/wk). They also had a significantly faster decline compared to placebo on a composite measure of ADAS, MMSE, and various other cognitive tests (-0.011/wk vs. -0.001/wk).

Conclusions: Long-term use of atypical antipsychotics for behavioural symptoms and psychosis in dementia patients is associated with greater rates of cognitive decline.

Major or Mild NCD with Lewy Bodies (formerly Dementia with Lewy Bodies)

Definition

- A NCD characterized by progressive cognitive impairment (with early changes in complex attention and executive function) and recurrent complex visual hallucinations
- core diagnostic features
 - fluctuating cognition with pronounced variations in attention and alertness
 - recurrent visual hallucinations that are well formed and detailed
 - spontaneous features of parkinsonism, with onset subsequent to development of cognitive decline (rest tremor may be absent in DLB, but otherwise same classic features of Parkinson's disease)
- suggestive/supportive features
 - rapid eye movement (REM) sleep behaviour disorder
 - severe sensitivity to neuroleptic medications (rigidity, neuroleptic malignant syndrome, extrapyramidal symptoms)
 - repeated falls, syncope, or transient episodes of unexplained loss of consciousness
 - auditory or other nonvisual hallucinations, systematic delusions, and depression

Etiology and Pathogenesis

- Lewy bodies (eosinophilic cytoplasmic inclusions) found in both cortical and subcortical structures
- mixed DLB and AD pathology is common

Diagnostically Suggestive Markers

- low striatal dopamine transporter uptake on SPECT or PET
- relative preservation of medial temporal structures on CT/MRI

Epidemiology

- 0.1-5% of the general elderly population
- Lewy bodies are present in 20-35% of all dementia cases (more common in males)

Treatment

- acetylcholinesterase inhibitors (e.g. donepezil)

Prognosis

- average duration of survival 5-7 yr

Major or Mild Frontotemporal NCD (formerly Frontotemporal Dementia)

Definition

- refers to a group of disorders caused by progressive cell degeneration in the brain's frontal or temporal lobes
 - deficits in executive function (e.g. poor mental flexibility, abstract reasoning, response inhibition, planning/organization, increased distractibility) with relative sparing of learning, memory and perceptual-motor function
- "probable" is distinguished from "possible" frontotemporal NCD by:
 - evidence of causative frontotemporal NCD genetic mutation, from either family history or genetic testing
 - evidence of disproportionate frontal and/or anterior temporal atrophy on MRI or CT
 - evidence of frontal and/or anterior temporal hypoperfusion or hypometabolism on PET or SPECT

Behavioural Variant FTD

- most common variant
- insidious onset: must show progressive deterioration of behaviour and/or cognition by observation or history
- typically early symptom presentation (i.e. within the first 3 yr)
- three out of the following symptoms must be present and persistent/recurrent:
 - behavioural disinhibition (socially inappropriate behaviour, impulsive, careless)
 - apathy or inertia (decreased initiation or continuation of behaviour, requiring cues/prompts, less likely to initiate or sustain conversations)
 - loss of sympathy or empathy (diminished response to others' needs/feelings, social interest)
 - preservative, stereotyped, or compulsive/ritualistic behaviour
 - hyperorality and dietary changes (binge eating, increased consumption of alcohol/cigarettes or inedible objects)

Language Variants (Primary Progressive Aphasia)

- prominent decline in language ability, in the form of speech production, word finding, object naming, grammar, or word comprehension
- three subtypes
 - nonfluent/agrammatic variant PPA (NFAV-PPA) or progressive nonfluent aphasia (PNFA): non-fluent, laboured articulation/speech, anomia, preserved single word comprehension, word-finding deficit, impaired repetition
 - semantic variant PPA (SV-PPA) or semantic dementia (SD): fluent, normal rate, anomia, impaired single word comprehension, intact repetition, use words of generalization (“thing”) or supraordinate categories (“animal” for “dog”)
 - logopenic progressive aphasia (LPA): naming difficulty and impaired repetition

FTD Movement Disorders

- corticobasal degeneration (CBD) (*see Parkinsonism*)
- progressive supranuclear palsy (PSP) (*see Parkinsonism*)

Etiology and Pathogenesis

- unknown, however there is likely a genetic/familial component (40% have family history of early onset NCD)
- genetic variants: MAPT gene (Tau), PGRN gene (progranulin), VCP gene, TARDBP gene (TDP-43), CHMP2D gene
- unlike AD, FTD does not show amyloid plaques or neurofibrillary tangles, instead it is characterized by severe atrophy and specific neuronal inclusion bodies
- gross changes: atrophy in the frontal and anterior temporal lobes; cortical thinning; possible ventricular enlargement
- histological changes: gliosis, swollen neurons, microvacuolation, inclusion bodies in neurons/glia (Tau or TDP-43)

Epidemiology

- fourth most common cause of dementia (5% of all dementia cases)
- common cause of early-onset NCD in individuals younger than 65 yr

Prognosis

- median survival being 6-11 yr after symptoms onset and 3-4 yr after diagnosis
- survival is shorter and decline is faster than in typical Alzheimer’s disease

Major or Mild Vascular NCD

Definition

- diagnosis of major or mild NCD with determination of CVD as the dominant if not exclusive pathology that accounts for the cognitive deficits
- vascular etiology suggested by one of the following:
 - onset of cognitive deficits is temporally related to one or more cerebrovascular events
 - evidence for decline is prominent in complex attention (including processing speed) and frontal-executive function
- neuroimaging evidence of cerebrovascular disease comprises one or more of the following:
 - one or more large vessel infarct or hemorrhage
 - a strategically placed single infarct or hemorrhage (e.g. angular gyrus, thalamus, basal forebrain)
 - two or more lacunar infarcts outside the brainstem
 - extensive and confluent white matter lesions
- for mild vascular NCD: history of a single stroke or extensive white matter disease is sufficient
- for major vascular NCD: history of two or more strokes, a strategically placed stroke, or a combination of white matter disease and one or more lacunae is generally necessary
- associated features supporting diagnosis: personality and mood changes, abulia, depression, emotional lability, and psychomotor slowing

Etiology and Pathogenesis

- major risk factors are the same as those for CVD (i.e. HTN, DM, smoking, obesity, high cholesterol levels, high homocysteine levels, other risk factors for atherosclerosis, atrial fibrillation, and conditions increasing risk of cerebral emboli)
- major or mild vascular NCD with gradual onset and slow progression is generally due to small vessel disease leading to lesions in white matter, basal ganglia, and/or thalamus
- cognitive deficits can be attributed to disruption of cortical-subcortical circuits

Epidemiology

- second most common cause of NCD
- prevalence estimates for vascular dementia/NCD range from 0.2-13% (by age 70), 16% (ages 80+) to 44.6% (ages 90+)
- higher prevalence in African Americans compared to Caucasians and East Asians
- prevalence higher in males than in females

Creutzfeldt-Jakob Disease

- rare degenerative fatal brain disorder caused by prion proteins causing spongiform changes, astrocytosis, and neuronal loss
- most common forms are sporadic (85%), hereditary (5-10%), and acquired (<1%)
- investigations: CSF analysis, MRI brain (cortical and/or subcortical FLAIR changes), EEG (periodic complexes)
- definitive diagnosis is by brain biopsy
- no treatments currently exist

Prion proteins have a normal form and an infectious form, which results from conversion of the protein from α -helix (normal) to β -pleated sheet (abnormal); these abnormally folded proteins aggregate leading to neuronal loss

Aphasia

Definition

- an acquired disturbance of language characterized by errors in language production, writing, comprehension, or reading

Neuroanatomy of Aphasia

- Broca's area (posterior inferior frontal lobe) involved in language production (expressive)
- Wernicke's area (posterior superior temporal lobe) involved in comprehension of language (receptive)
- angular gyrus is responsible for relaying written visual stimuli to Wernicke's area for reading comprehension
- arcuate fasciculus association bundle connects Wernicke's and Broca's areas

Assessment of Language

- assessment of context
 - handedness (writing, drawing, toothbrush, scissors), education level, native language, learning difficulties
- assessment of aphasia
 - spontaneous speech (fluency, paraphasias, repetition, naming, comprehension – auditory and reading, writing, neologisms)

> 99% of right-handed people have left hemisphere language representation

70% of left-handed people have left hemisphere language representation, 15% have right hemisphere representation, and 15% have bilateral representation

Types of Paraphasias

Semantic ("chair" for "table")
Phonemic ("clable" for "table")

Aphasia localizes the lesion to the dominant cerebral hemisphere

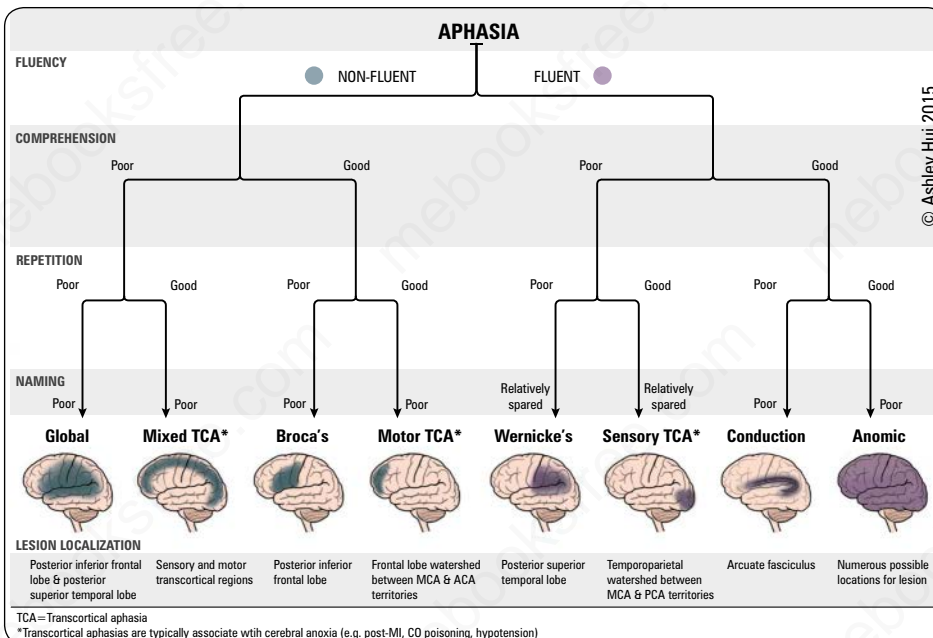

Figure 19. Aphasia classification

Apraxia

Definition

- inability to perform skilled voluntary motor sequences that cannot be accounted for by weakness, ataxia, sensory loss, impaired comprehension, or inattention

Clinicopathological Correlations

Table 14. Apraxia

	Description	Tests	Hemispheres
Ideomotor	Inability to perform skilled learned motor sequences	Blowing out a match; combing one's hair	Left
Ideational	Inability to sequence actions	Preparing and mailing an envelope	Right and left
Constructional*	Inability to draw or construct	Copying a figure	Right and left
Dressing*	Inability to dress	Dressing	Right

*Refers specifically to the inability to carry out the learned movements involved in construction, drawing, or dressing; not merely the inability to construct, draw, or dress. Many skills aside from praxis are needed to carry out these tasks

Agnosia

Definition

- disorder in the recognition of the significance of sensory stimuli in the presence of intact sensation and naming

Clinicopathological Correlations

Table 15. Agnosias

	Description	Lesion
Apperceptive Visual Agnosia	Inability to name or demonstrate the use of an object presented visually 2° to distorted visual perception Recognition by touch remains intact	Bilateral temporo-occipital cortex
Associative Visual Agnosia	Inability to name an object presented visually 2° to disconnect between visual cortex and language areas Visual perception is intact as demonstrated by visual matching	Bilateral inferior temporo-occipital junction
Prosopagnosia	Inability to recognize familiar faces in the presence of intact visual perception and intact auditory recognition	Bilateral temporo-occipital areas or right inferior temporo-occipital region
Colour Agnosia	Inability to perceive colour	Bilateral inferior temporo-occipital lesions
Impaired Stereognosis	Inability to identify objects by touch	Anterior parietal lobe in the hemisphere opposite the affected hand
Finger Agnosia	Inability to recognize, name, and point to individual fingers	Dominant hemisphere parietal-occipital lesions

Parietal Lobe Lesions

- Lesions of the dominant parietal lobe are characterized by Gerstmann's syndrome: acalculia, agraphia, finger agnosia, and left-right disorientation
- Lesions of the non-dominant parietal lobe are characterized by neglect, anosognosia, and asomatognosia
- Cortical sensory loss (graphesthesia, astereognosis, impaired 2 point discrimination and extinction) can be seen with left or right parietal lesions

- Extent of retrograde amnesia correlates with severity of injury
- Regained from most distant to recent memories

Mild Traumatic Brain Injury

Definition

- mild TBI = concussion
- trauma induced transient alteration in mental status that may involve loss of consciousness
- hallmarks of concussion: confusion and amnesia, which may occur within minutes
- loss of consciousness (if present) must be less than 30 min, initial GCS must be between 13-15, and post-traumatic amnesia must be less than 24 h

Epidemiology

- 75% of TBIs are estimated to be mild; remainder are moderate or severe (see [Neurosurgery, NS30 and Emergency Medicine, ER8](#))
- highest rates in children 0-4 yr, adolescents 15-19 yr, and elderly >65 yr

Clinical Features

- impairments following mild TBI
 - somatic: headache, sleep disturbance, nausea, vomiting, blurred vision
 - cognitive dysfunction: attentional impairment, reduced processing speed, drowsiness, amnesia
 - emotion and behaviour: impulsivity, irritability, depression
- severe concussion: may precipitate seizure, bradycardia, hypotension, sluggish pupils
- associated conditions: brain contusion, diffuse axonal injury, C-spine injury

Investigations

- neurological exam to identify focal neurologic deficits
- neurocognitive assessment
 - simple orientation questions are inadequate to detect cognitive changes
 - initial assessment of severity is determined by
 - ♦ Glasgow Coma Scale: mild: 13-15, moderate: 9-12, severe: 3-8
 - sideline evaluation: Standardized Assessment of Concussion, Westmead Post-Traumatic Amnesia Scale, Sport Concussion Assessment Tool
- neuroimaging
 - x-ray of skull: not indicated for routine evaluation of MTBI
 - CT head as indicated by Canadian CT Head Rules ([see Emergency Medicine, ER8](#))
 - MRI not indicated in initial evaluation – indicated in presence of continued or worsening symptoms despite normal CT

Treatment

- observation for first 24 h after mild TBI in all patients because of risk of intracranial complications
- emergency department for assessment if any loss of consciousness or persistent symptoms
- hospitalization with normal CT if GCS <15, seizures, or bleeding diathesis; or abnormal CT scan
- early rehabilitation to maximize outcomes
 - OT, PT, SLP, vestibular therapy, driving, therapeutic recreation
- pharmacological management of headaches, pain, depression
- CBT, relaxation therapy
- follow Return to Play guidelines (www.thinkfirst.ca)

Prognosis

- most recover from mild TBI with minimal treatment, but some experience long-term consequences
- Patients with a previous concussion are at increased risk of subsequent concussion and cumulative brain injury
- repeat TBI can lead to life threatening cerebral edema (controversially known as second impact syndrome) or permanent impairment
- sequelae include
 - post-concussion syndrome: dizziness, headache, neuropsychiatric symptoms, cognitive impairment (usually resolves within weeks to months)
 - post-traumatic headaches: begin within 7 d of injury
 - post-traumatic epilepsy: approximately 2% risk of epilepsy post-mild TBI, prophylactic anticonvulsants not effective
 - post-traumatic vertigo

Neuro-Oncology

Paraneoplastic Syndromes

- see [Endocrinology, E48](#)

Tumours of the Nervous System

- see [Neurosurgery, NS39](#)

Movement Disorders

Function of the Basal Ganglia

- the cerebral cortex initiates movement via excitatory (glutamatergic) projections to the striatum, which then activate two pathways: direct and indirect
- direct: cortex activates the thalamus allowing movement
- indirect: inhibits the thalamus and ultimately prevents movement

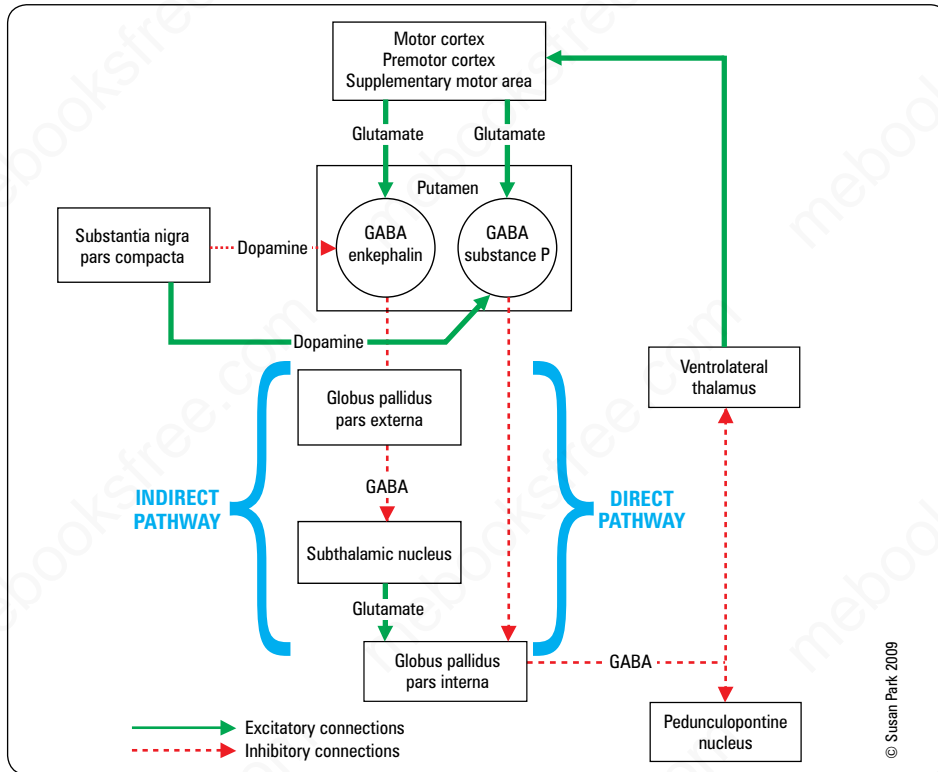

Figure 20. Neural connections of the basal ganglia

Figure 21. Horizontal section of basal ganglia

Overview of Movement Disorders

Table 16. Movement Disorder Definitions

Akathisia	Subjective generalized restlessness relieved by voluntary stereotypic movements (e.g. squirming)
Asterixis	Transient loss of muscle tone (negative myoclonus)
Athetosis	Slow writhing movements, especially distally
Bradykinesia	Slow and/or small amplitude of movements
Chorea	Brief, flowing, irregular movements; can appear purposeful in milder forms
Dysdiadochokinesia	Inability to smoothly perform rapidly alternating movements
Dyskinesia	Any involuntary movement, but the term is often used to describe the stereotypical movements that come with long-term neuroleptic use (tardive dyskinesia)
Dystonia	Co-contraction of agonist and antagonist muscles causing sustained twisting movements which can be tonic (dystonic postures) or phasic (dystonic movements)
Freezing	Episodes of halted motor action, especially during repetitive actions (eg. walking)
Hemiballismus	Unilateral violent flinging movement
Myoclonus	Brief muscle group contraction that is either focal, segmental, or generalized
Myokymia	Spontaneous, fine, fascicular contraction of muscle
Tachykinesia	Acceleration of movements
Tics	Stereotyped and brief repetitive actions due to inner urge; can be suppressed; can be phonic (vocal) or motor
Tremor	Rhythmic and involuntary alternating muscle contractions

In some cases, dystonias may only occur during voluntary movement and sometimes only during specific activities such as writing, chewing, or speaking (task-specific dystonia)

Hemiballismus is most often due to a vascular lesion of the contralateral subthalamic nucleus

Myoclonus is often stimulus-sensitive as it can be induced by sudden noise, movement, light, visual threat, or pinprick

Movement Disorders

Differential Diagnoses

1. Tremor

Table 17. Approach to Tremors

	Resting	Action-Postural	Action-Intention
Body Part	UE>jaw>LE>head	UE>head>LE>tongue	UE>voice>LE
Characteristics	3-7 Hz pill rolling	6-12 Hz fine tremor	<5 Hz coarse tremor
Worse with Associated Sx	Rest while concentrating "TRAP"	Sustained posture (outstretched arms) ± Autosomal dominant FHx	Finger to nose Cerebellar findings
DDx	PD, Parkinsonism, Wilson's disease, mercury poisoning	Physiologic, essential, hyperthyroidism, hyperglycemia, heavy metal poisoning, CO poisoning, drug toxicity, sedative/alcohol withdrawal	Cerebellar disorders, Wilson's disease, MS, anticonvulsants, alcohol, sedatives
Treatment	Carbidopa-levodopa (Sinemet®), surgery, DBS	Propranolol, primidone, topiramate, and other anticonvulsants	Treat underlying cause

In a young patient (<45) must do TSH (thyroid disease), ceruloplasmin (Wilson's disease), and CT/MRI (cerebellar disease) as indicated by type of tremor

The majority of essential tremor does not need treatment

Alcohol

- Dampens essential tremor
- Potentiates intention tremor during abstinence (delirium tremens)
- Does not improve resting tremor of PD

Most common cause of chorea is drug therapy for PD (L-dopa induced dyskinesias)

2. Chorea: Huntington's disease (HD), HD-like syndromes, neuroacanthocytosis, SLE, APLA syndrome, Wilson's disease, CVD, tardive dyskinesia, senile chorea, Sydenham's chorea, pregnancy chorea (chorea gravidarum)

3. Dystonia

- **primary dystonia:** familial, sporadic (torticollis, blepharospasm, writer's cramp)
- **dystonia-plus syndromes:** dopa-responsive dystonia, myoclonus-dystonia
- **secondary dystonia:** thalamotomy, stroke, CNS tumour, demyelination, PNS injury, drugs/toxins (L-dopa, neuroleptics, anticonvulsants, Mn, CO, cyanide, methanol)
- **heredodegenerative dystonias:** Parkinsonian disorders, Wilson's disease, Huntington's disease

4. Myoclonus

- **physiologic myoclonus:** hiccups, nocturnal myoclonus
- **essential myoclonus:** myoclonus-dystonia with minimal or no occurrence of dystonia
- **epileptic myoclonus**
- **symptomatic myoclonus**
- **degenerative disorders:** Wilson's disease, Huntington's disease, Corticobasal degeneration
- **infectious disorders:** CJD, viral encephalitis, AIDS-dementia complex
- **metabolic disorders:** drug intoxication/withdrawal, hypoglycemia, hyponatremia, HHS, hepatic encephalopathy, uremia, hypoxia
- **focal brain damage:** head injury, stroke, mass

Palatal myoclonus can result from lesion to the Dentato-Rubro-Olivary tract, and is associated with an audible clicking and tremor of other facial muscles

Parkinson's Disease

Etiology

- sporadic: combination of oxidative stress to dopaminergic neurons, environmental toxins (e.g. pesticides), accelerated aging, genetics
- familial (10%): autosomal dominant α -synuclein or LRRK2 mutations, autosomal recessive parkin, PINK1 or DJ-1 mutation (juvenile onset)
- MPTP (neurotoxin)

Epidemiology

- prevalence of 0.3% in industrialized countries, but rises with increased age
- second most common neurodegenerative disorder, after Alzheimer's
- mean age of onset is 60 yr

Associated Factors

- risk: family history, male, head injury, rural living, exposure to certain neurotoxins
- protective: coffee drinking, smoking, NSAID use, estrogen replacement in post-menopausal women

Pathophysiology

- loss of dopaminergic neurons in pars compacta of substantia nigra \rightarrow decreased dopamine in striatum \rightarrow 1. disinhibition of the indirect pathway & 2. decreased activation of the direct pathway \rightarrow increased inhibition of cortical motor areas
- α -synucleinopathy: α -synuclein accumulates in Lewy bodies and causes neurotoxicity in substantia nigra

Clinical Features

- positive motor
 - resting tremor: asymmetric 4-5 Hz "pill-rolling" tremor, especially in hands
 - rigidity: lead-pipe rigidity with cogwheeling due to superimposed tremor
- negative motor
 - bradykinesia: slow, small amplitude movements, fatiguing of rapid alternating movements, difficulty initiating movement
- related findings: masked facies, hypophonia, aprosody (monotonous speech), dysarthria, micrographia, shuffling gait with decreased arm swing
- freezing of gait: occurs with walking triggered by initiating stride or barriers/destinations, lasting seconds
- postural instability: late finding presenting as falls
- cognition: bradyphrenia (slow to think/respond), dementia (late finding)
- behavioural: decreased spontaneous speech, depression, sleep disturbances, anxiety
- autonomic: constipation, urinary retention, sexual dysfunction, orthostatic hypotension, clinostatic hypertension

Treatment

- **pharmacologic**
 - mainstay of treatment: levodopa/carbidopa (Sinemet[®]) or levodopa/benserazide (Prolopa[®]). Levodopa is a dopamine precursor; carbidopa and benserazide decreases peripheral metabolism of levodopa, decreasing side effects and increasing half-life of levodopa
 - ♦ levodopa-related fluctuation: delayed onset of response (affected by mealtime), end-of-dose deterioration ("wearing-off"), random oscillations of on-off symptoms
 - ♦ major complication of levodopa is dyskinesia
 - treatment of early PD: dopamine agonists, amantadine, MAOI
 - adjuncts: dopamine agonists, MAOI, anticholinergics (especially if prominent tremors), COMT inhibitors
- **surgical**
 - thalamotomy
 - pallidotomy
 - DBS (thalamic, pallidal, subthalamic)
- **psychiatric**
 - SSRIs first line
 - TCAs (beware fall risk, cognitive impairment, and worsening symptoms of Parkinson's disease)

Other Parkinsonian Disorders

- **NCD with Lewy bodies** (*see Behavioural Neurology, N25*)
- **progressive supranuclear palsy**: tauopathy with limited vertical gaze (downgaze more specific), early falls, axial rigidity and akinesia, dysarthria, and dysphagia
- **corticobasal syndrome**: tauopathy with varied presentations but classically presents with unilateral parkinsonism, dystonia/myoclonus, apraxia \pm "alien limbs" phenomenon; may also present as progressive non-fluent aphasia
- **multiple system atrophy**: synucleinopathy presenting as either cerebellar predominant (MSA-C, previously olivopontocerebellar atrophy) or parkinsonism predominant (MSA-P, previously nigrostriatal degeneration); both are associated with early autonomic dysfunction (previously Shy-Drager syndrome)
- **vascular parkinsonism**: multi-infarct presentation with gait instability and lower body parkinsonism; less likely associated with tremor

Key Parkinsonian Features

TRAP

- Tremor (resting)
- Rigidity
- Akinesia/bradykinesia
- Postural instability

2015 MDS Clinical Diagnostic Criteria for PD

"Clinically Established PD" requires:

- Cardinal Parkinsonism Manifestations: Bradykinesia with either rest tremor or rigidity
- 2 or more supportive criteria (clear and dramatic beneficial response to dopaminergic therapy, levodopa-induced dyskinesia, rest tremor of a limb, olfactory loss/cardiac sympathetic denervation on MIBG scintigraphy)
- No absolute exclusion criteria and no red flags (see full diagnostic criteria - Postuma et al (2015). Mov Disord.)

Consider an Alternative Diagnosis if Atypical Parkinsonism

- Poor response to levodopa
- Abrupt onset of symptoms
- Rapid progression
- Early falls
- Early autonomic dysfunction
- Symmetric symptoms at onset
- Early age of onset (<50 yr)
- Early cognitive impairment
- FHx of psychiatric/dementing disorders
- Recent diagnosis of psychiatric disease
- History of encephalitis
- Unusual toxin exposure
- Extensive travel history

Dopamine Agonist Therapy in Early Parkinson's Disease

Cochrane DB Syst Rev 2009;2:CD006564

Study: Meta-analysis of trials of dopamine agonists in early Parkinson's disease.

Results: Twenty-nine trials were included (n=5,247). Dopamine agonists were found to have decreased motor side effects (dyskinesia [OR 0.51], dystonia [OR 0.64], motor fluctuations [OR 0.75]) compared to levodopa, but provided poorer symptom control compared to levodopa. Also, other side effects were increased (constipation [OR 1.59], hallucinations [OR 1.69], dizziness [OR 1.45]).

Conclusion: Dopamine agonists have fewer motor side effects than levodopa, but provide worse symptom control and increased rate of other side effects.

Huntington's Disease

Etiology and Pathogenesis

- genetics: autosomal dominant CAG repeats (with anticipation) in Huntington's gene on Chromosome 4, which leads to accumulation of defective protein in neurons
- pathology: global cerebral atrophy, especially affecting the striatum, leading to increased activity of the direct pathway, and decreased activity of the indirect pathway

Epidemiology

- North American prevalence 4-8/100,000
- mean age of onset 35-44 yr; but varies with degree of anticipation from 5-70 yr

Clinical Features

- typical progression: insidious onset with clumsiness, fidgetiness, and irritability, progressing over 15 yr to major NCD, psychosis, and chorea
 - major NCD: progressive memory impairment and loss of intellectual capacity
 - chorea: begins as movement of eyebrows and forehead, shrugging of shoulders, and parakinesia (pseudo-purposeful movement to mask involuntary limb jerking)
 - progresses to dance-like or ballism, and in late stage is replaced by dystonia and rigidity
 - mood changes: irritability, depression, anhedonia, impulsivity, bouts of violence
- Juvenile-onset HD (Westphal variant) characterized by Parkinsonism and dystonia

Investigations

- MRI: enlarged ventricles, atrophy of cerebral cortex and caudate nucleus
- genetic testing
 - expansion of the cytosine-adenine-guanine (CAG) trinucleotide repeats in the HTT gene
 - CAG repeats on chromosome 4p16.3 that encodes the protein huntingtin

Treatment

- no disease altering treatment
- psychiatric symptoms: antidepressants and antipsychotics
- chorea: neuroleptics and benzodiazepines
- dystonia: botulinum toxin

Dystonia

Epidemiology

- third most common movement disorder after Parkinson's disease and essential tremor

Clinical Features

- sustained twitching movements caused by co-contraction of agonist and antagonist muscles
- symptoms exacerbated by fatigue, stress, emotions; relieved by sleep or specific tactile/proprioceptive stimuli ('geste antagoniste', e.g. place hand on face for cervical dystonia)
- more likely to be progressive and generalize if younger onset or leg dystonia

Treatment

- local medical: botulinum toxin
- systemic medical: anticholinergics (benztropine), muscle relaxants (baclofen), benzodiazepines, dopamine depletors (tetraabenazine); dopamine for dopa-responsive dystonia
- surgical: surgical denervation of affected muscle, stereotactic thalamotomy (unilateral dystonia), posteroventral pallidotomy, or DBS

Tic Disorders

Definition

- a tic is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalization
- common criteria
 - tics may wax and wane in frequency but have persisted for an extended period of time
 - onset before age 18 yr
 - disturbance is not attributable to the physiological effects of a substance or another medical condition

Clinical Classification

- Tourette's Syndrome:** multiple motor and one or more vocal tics that have persisted for more than 1 yr since onset
- persistent (chronic) motor or vocal tic disorder:** single or multiple motor or vocal tics (but not both motor and vocal) that have persisted for more than 1 yr since onset
- provisional tic disorder:** single or multiple motor and/or vocal tics present for <1 yr since first tic onset
- other specified or unspecified tic disorder: symptoms characteristic of a tic disorder but do not meet full criteria
- secondary tic disorders:** encephalitis, CJD, Sydenham's chorea, head trauma, drugs, mental retardation syndromes

Tic Types

- simple tics: short duration (milliseconds)
- complex tics: longer (seconds), more purposeful and often include a combination of simple tics
- motor tics
 - simple: blinking, head jerking, shoulder shrugging, extension of the extremities
 - dystonic: bruxism (grinding teeth), abdominal tension, sustained mouth opening
 - complex: copropraxia (obscene gestures), echopraxia (imitate gestures), throwing, touching
- vocal tics
 - simple: blowing, coughing, grunting, throat clearing
 - complex: coprolalia (shout obscenities), echolalia (repeat others' phrases), palilalia (repeat own phrases)

Treatment

- dopamine blockers, dopamine depletors (tetrabenazine), clonidine, clonazepam, DBS

Tourette's Syndrome (Gilles de la Tourette Syndrome)**Definition According to DSM V**

1. presence of both multiple motor and one or more vocal tics at some point during the illness, although not necessarily concurrently
2. tics may wax and wane in frequency but have persisted for more than 1 yr since first tic onset (with no tic-free periods greater than 3 mo)
3. onset is before age 18 yr
4. not due to effect of a substance or another medical condition

Epidemiology

- estimated prevalence among adolescents 3-8 per 1,000 school-age children; M:F = 2:1 to 4:1

Signs and Symptoms

- tics: wide variety that wax and wane in type and severity; can be voluntarily suppressed for some time but are preceded by unpleasant sensation that is relieved once tic is carried out
 - can be worsened by anxiety, excitement, and exhaustion; better during calm focused activities
- psychiatric: compulsive behaviour (associated with OCD and ADHD), hyperactive behaviour, 'rages', sleep-wake disturbances, learning disabilities

Treatment

- same as tics (dopamine blockers, dopamine depletors, clonidine, clonazepam, DBS)

Prognosis

- typically begins between ages 4-6
- peak severity occurs between ages 10-12, with a decline in severity during adolescence (50% are tic-free by 18 yr of age)
- tic symptoms, however, can manifest similarly in all age groups and across the lifespan

Cerebellar Disorders**Clinico-Anatomic Correlations**

- **vermis**: trunk/gait ataxia
- **cerebellar lobe** (i.e. lateral): rebound phenomenon, scanning dysarthria, dysdiadochokinesia, dysmetria, nystagmus

Symptoms and Signs of Cerebellar Dysfunction

- nystagmus: observe during extraocular movement testing (most common is gaze-evoked nystagmus)
- dysarthria (ataxic): abnormal modulation of speech velocity and volume – elicit scanning/telegraphic/slurred speech on spontaneous speech
- ataxia: broad-based, uncoordinated, lurching gait
- dysmetria: irregular placement during voluntary movement of limb or eye
- dysdiadochokinesia: impairment of rapid alternating movements (e.g. pronation – supination task)
- postural instability: truncal ataxia on sitting, titubation (rhythmic rocking of trunk and head), difficulty with tandem and broad-based gait
- intention tremor: typically orthogonal to intended movement, and increases as target is approached
- hypotonia: decreased resistance to passive muscular extension (occurs shortly after injury to lateral cerebellum)
- pendular patellar reflex: knee reflex causes pendular motion of leg (occurs after injury to cerebellar hemispheres); pendular reflexes at triceps
- rebound phenomenon: overcorrection after displacement of a limb
- hypometric and hypermetric saccades

Wernicke-Korsakoff Syndrome

- see [Psychiatry, PS24](#)
- note that alcohol can also cause a cerebellar ataxia separate from thiamine deficiency; this ataxia can be due to cerebellar atrophy or alcohol polyneuropathy

Cerebellar Ataxias

Congenital Ataxias

- early onset non-progressive ataxias associated with various syndromes as well as developmental abnormalities (e.g. Arnold-Chiari malformation, Dandy-Walker cysts)

Hereditary Ataxias

- **autosomal recessive:** includes Friedrich's ataxia, ataxia with oculomotor apraxia, ataxia telangiectasia, vitamin E deficiency
 - Friedrich's ataxia: prevalence 2/100,000; typical onset between 8 and 15 yr
 - ♦ signs: gait and limb ataxia, weakness, areflexia, extensor plantar reflex, impaired proprioception and vibration, dysarthria
 - ♦ death in 10-20 yr from cardiomyopathy or kyphoscoliotic pulmonary restriction
- **autosomal dominant:** most commonly spinocerebellar ataxias (SCAs) (over 30 types, most common SCAs due to CAG repeats)
 - signs: ataxia and dysarthria, chorea, polyneuropathy, pyramidal and/or extrapyramidal features, dementia

Acquired Ataxias

- neurodegeneration: e.g. multiple system atrophy
- systemic: alcohol, celiac sprue, hypothyroidism, Wilson's, thiamine deficiency
- toxins: carbon monoxide, heavy metals, lithium, anticonvulsants, solvents
- vascular: infarct, bleed, basilar migraine
- autoimmune: MS, Miller-Fischer (GBS)

Vertigo

- see [Otolaryngology, OT12](#)

Motor Neuron Disease

Amyotrophic Lateral Sclerosis (Lou Gehrig's Disease)

Definition

- progressive neurodegenerative disease that causes UMN and LMN symptoms and is ultimately fatal

Etiology

- idiopathic (most), genetic (5-10% familial, especially SOD1 mutation, other: C9orf72, TARDBP)

Pathology

- disorder of anterior horn cells of spinal cord, cranial nerve nuclei, and corticospinal tract

Epidemiology

- 5/100,000; incidence increases with age

Clinical Features

- limb motor symptoms: segmental and asymmetrical UMN and LMN symptoms
- bulbar findings: dysarthria (flaccid or spastic), dysphagia, tongue atrophy and fasciculations, facial weakness and atrophy
- pseudobulbar affect, frontotemporal dementia (up to 10%)
- sparing of sensation, ocular muscles, bowel, bladder, sphincters

Investigations

- EMG: chronic denervation and reinnervation, fasciculations
- NCS: to rule out peripheral neuropathy (i.e. multifocal motor neuropathy with conduction block)
- CT/MRI: to rule out cord disease/compression

The only interventions that have been shown to extend survival in ALS are riluzole and use of BiPAP

Red Flags Inconsistent with ALS

Sensory Sx, predominant pain, bowel or bladder incontinence, cognitive impairment, ocular muscle weakness

Denervation on EMG

Fibrillations, positive sharp waves, complex repetitive discharges; reinnervation – increased amplitude and duration of motor units

Treatment

- riluzole (modestly slows disease progression)
- symptomatic relief
 - spasticity/cramping: baclofen, tizanidine (Zanaflex®), regular exercise, and physical therapy
 - sialorrhea: TCA (i.e. amitriptyline), sublingual atropine drops, parotid/submandibular Botox® (rare)
 - pseudobulbar affect: dextromethorphan/quinidine, TCA, SSRI
- non-pharmacologic: high caloric diet, ventilatory support (especially BiPAP), early nutritional support (i.e. PEG tube), rehabilitation (PT, OT, SLP), psychosocial support

Prognosis

- median survival 3 yr; death due to respiratory failure

Other Motor Neuron Diseases

- degenerative
 - **progressive muscular atrophy** (progressive bulbar palsy): only LMN symptoms with asymmetric weakness, later onset than ALS, 5-10% of patients in ALS centres
 - **primary lateral sclerosis** (progressive pseudobulbar palsy): UMN symptoms, later onset, not fatal, variable disability; 5-10% of patients in ALS centres
 - **spinal muscular atrophy**: pediatric disease with symmetric LMN symptoms
- infectious
 - post-polio syndrome, West Nile infection: residual asymmetric muscle weakness, atrophy

Peripheral Neuropathies

Diagnostic Approach to Peripheral Neuropathies

1. differentiate: motor vs. sensory vs. autonomic vs. mixed
2. pattern of deficit: symmetry; focal vs. diffuse; upper vs. lower limb; cranial nerve involvement
3. temporal pattern: acute vs. chronic; relapsing/remitting vs. constant vs. progressive
4. history: PMH, detailed FHx, exposures (e.g. insects, toxins, sexual, travel), systemic symptoms
5. detailed peripheral neuro exam: LMN findings, differentiate between root and peripheral nerves, cranial nerves, respiratory status

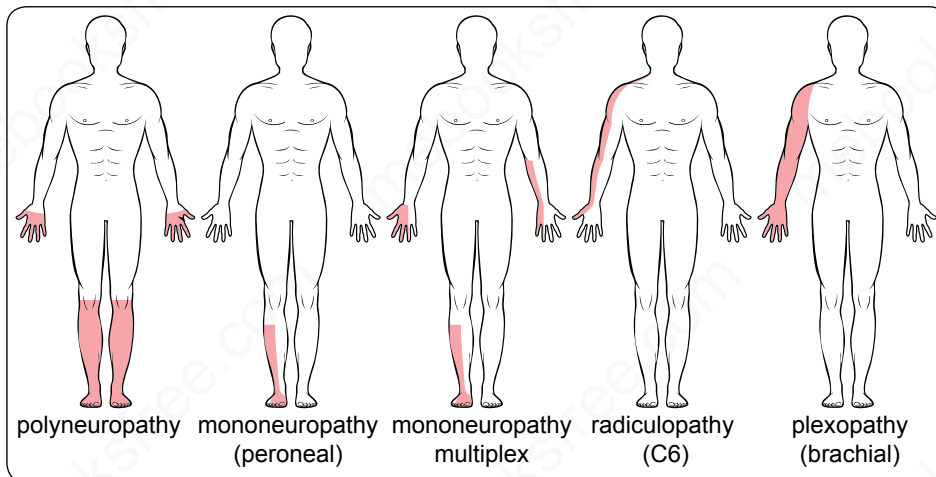

Figure 22. Pattern of distribution for peripheral neuropathies

Classification

- **monoradiculopathy**: dermatomal deficit due to single nerve root lesion
 - due to disc herniation or root compression causing radicular pain
 - little tactile anesthesia, as dermatomes overlap
- **polyradiculopathy**: multiple dermatome deficits due to multiple nerve root lesions
 - one type is cauda equina syndrome (lumbosacral roots)
- **plexopathy**: deficit matching distribution of a nerve plexus
 - **brachial plexopathy**
 - ♦ upper (C5-C7): LMN Sx of shoulder and upper arm muscles (Erb's palsy)
 - ♦ lower (C8-T1): LMN Sx and sensory Sx of forearm and hand (Klumpke's palsy)
 - ♦ DDx: trauma, idiopathic neuritis, tumour infiltration, radiation, thoracic outlet syndrome (i.e. cervical rib)
 - **lumbosacral plexopathy** (rare, especially unilateral)
 - ♦ DDx: idiopathic neuritis, infarction (i.e. DM), compression

Diabetic Neuropathies

- Peripheral neuropathy: pain or loss of sensation in a glove and stocking distribution (hands and feet affected before arms and legs)
- Autonomic: anhidrosis, orthostatic hypotension, impotence, gastroparesis, bowel and bladder dysfunction
- Mononeuropathy multiplex: nerve infarct or compression
- Cranial neuropathy: CN III (pupil sparing) > IV > VI
- Lumbosacral plexopathy

Tinel's Sign

Tap lightly over the median nerve at the wrist, the patient's symptoms of carpal tunnel will be elicited in a positive test

Phalen's Test

Hold both wrists in forced flexion (with the dorsal surfaces of the hands pressed against each other) for 30-60 s; test is positive if symptoms of carpal tunnel are elicited

DDx of Demyelinating Neuropathy

GBS, CIDP, paraproteinemia, diphtheria, amiodarone, Charcot-Marie-Tooth, storage diseases, pressure palsy predisposition, paraneoplastic

- **mononeuropathy:** single nerve deficit
 - **carpal tunnel syndrome** (most common): compression of median nerve at wrist
 - ♦ symptoms: wrist pain, paresthesia first 3 and ½ digits, ± radiation to elbow, worse at night
 - ♦ signs: Tinel's sign, Phalen's test, thenar muscle wasting, sensory deficit
 - ♦ EMG and NCS: slowing at wrist (both motor and sensory)
 - ♦ etiology: entrapment, pregnancy, DM, gammopathy, rheumatoid arthritis, thyroid disease
 - **Bell's palsy** (most common cranial neuropathy): *see Otolaryngology, OT22*
 - **Entrapment/compression:** ulnar (compression at elbow), median (at pronator teres), radial (at spiral groove of humerus), obturator (from childbirth), peroneal (due to crossing legs or surgical positioning), posterior tibial (tarsal canal)
- **mononeuropathy multiplex:** deficit affecting multiple discrete nerves (asymmetric)
 - must rule out vasculitis or collagen vascular disease; consider MMN (multifocal motor neuropathy) or MADSAM (multifocal acquired demyelinating sensory and motor neuropathy)
- **polyneuropathy:** symmetrical distal stocking-glove pattern
 - symmetrical distal sensorimotor deficit affecting longest fibres first (stocking-glove distribution), hypotonia; progression of dysesthesia early and weakness later
 - etiology: DM (most common), renal disease, substances, toxins, genetics, SLE, HIV, leprosy, alcohol, B12 deficiency, uremia
 - **chronic inflammatory demyelinating polyneuropathy (CIDP)**
 - ♦ chronic relapsing sensorimotor polyneuropathy with increase protein in CSF and demyelination (shown on EMG/NCS)
 - ♦ course is fluctuating, in contrast with the acute onset of GBS
 - ♦ treatment: first-line is prednisone; alternatives are plasmapheresis, IVIG, and azathioprine

Axonal neuropathies have decreased amplitude on NCS; demyelinating neuropathies have decreased velocity on NCS

Ototoxic drugs (e.g. aminoglycosides) should not be given to diabetics
Sensory neuropathy of the feet prevent them from adequately compensating for loss of vestibular function

IVIG and plasmapheresis lead to more rapid improvement, less intensive care and less ventilation, but do not change mortality or relapse rate

Table 18. Differential Diagnosis of Symmetric Polyneuropathy

	Etiology	Mechanism	Course	Modalities	Investigations
Vascular	PAN	Ischemic	Chronic	S/M	See Rheumatology, RH19
	SLE	Ischemic	Chronic	S/M	See Rheumatology, RH11
	RA	Ischemic	Chronic	S/M	See Rheumatology, RH8
Infectious	HIV	Axonal/demyelination	Chronic	S/A	HIV serology
	Leprosy	Infiltrative	Acute	S/A	Leprosy serology Nerve biopsy
	Lyme	Axonal/demyelination	Chronic	M	Lyme serology
Immune	GBS	Demyelination	Acute	M	LP (↑ protein; no ↑ cells)
	CIDP	Demyelination	Chronic	S/M	LP (↑ protein)
Hereditary	HMSN	Axonal/demyelination	Chronic	S/M	Genetic testing
Neoplastic	Paraneoplastic	Axonal/demyelination	Chronic	S/M	Paraneoplastic antibodies
	Myeloma	Axonal/demyelination	Chronic	S/M	SPEP Skeletal bone survey
	Lymphoma	Axonal	Chronic	M	SPEP Bone marrow biopsy
	Monoclonal gammopathy	Demyelination	Chronic	S/M	SPEP Bone marrow biopsy
Toxin	EtOH	Axonal	Sub-acute	S/M	GGT, MCV
	Heavy metals (i.e. lead)	Axonal	Sub-acute	S/M	Urine heavy metals
	Medications	Axonal	Sub-acute	S/M	Drug levels
Metabolic	DM	Ischemic/axonal	Chronic	S/A	Fasting glucose, HbA1c, 2 h OGTT
	Hypothyroidism	Axonal	Chronic	S/M	TSH, T3, T4
	Renal failure	Axonal	Chronic	S/A	Electrolytes, Cr, BUN
Nutritional	B12 deficiency	Axonal	Sub-acute	S/M	Vitamin B12
Other	Porphyria	Axonal	Sub-acute	M	Urine porphyrins
	Amyloid	Axonal	Sub-acute	S	Nerve biopsy

Evaluation of Distal Symmetric Polyneuropathy: Role of Laboratory and Genetic Testing
Neurology 2009;72:185-192
Screening Lab Tests: Blood glucose, serum B12 with metabolites, serum protein immunofixation electrophoresis.
Genetic Testing: Indicated for cryptogenic polyneuropathy exhibiting classic hereditary neuropathy phenotype. Screen for CMT1A duplication/deletion and Cx32 mutations.

A = autonomic; CIDP = chronic inflammatory demyelinating polyneuropathy; GGT = gamma-glutamyl transferase; HMSN = hereditary motor sensory neuropathy; M = motor; OGTT = oral glucose tolerance test; PAN = polyarteritis nodosa; RA = rheumatoid arthritis; S = sensory; SLE = systemic lupus erythematosus; SPEP = serum protein electrophoresis

Guillain-Barré Syndrome

- **definition:** acute rapidly evolving demyelinating inflammatory polyradiculoneuropathy that often starts in the distal lower limbs and ascends
- **etiology**
 - autoimmune attack and damage to peripheral nerve myelin
 - sometimes preceded by viral/bacterial infections
- **signs and symptoms**
 - sensory: distal and symmetric paresthesias, loss of proprioception and vibration sense, neuropathic pain
 - motor: weakness starting distally in legs, areflexia
 - autonomic: blood pressure dysregulation, arrhythmias, bladder dysfunction
- **investigations**
 - CSF: albuminocytologic dissociation (high protein, normal WBC)
 - EMG/NCS: conduction block, differential or focal (motor > sensory) slowing, decreased F-wave, sural sparing
- **treatment**
 - IVIG or plasmapheresis, ± pain management, monitor vitals and vital capacity
- **prognosis**
 - peak of symptoms at 2-3 wk, resolution at 4-6 wk
 - 5% mortality (higher if require ICU); up to 15% have permanent deficits

GBS is a neurological emergency due to risk of imminent respiratory failure

The most common antecedent infection in GBS is *Campylobacter jejuni*

Miller-Fischer Variant of GBS – Triad

- Ophthalmoplegia
- Ataxia
- Areflexia

Neuromuscular Junction Diseases

Clinical Approach to Disorders of the Neuromuscular Junction

Table 19. Common Disorders of the Neuromuscular Junction

	Myasthenia Gravis	Lambert-Eaton	Botulism
Ocular/Bulbar Paresis	+	-	++ (early)
Limb Weakness	+	+	+
Fatigability	+	+	+
Post-Exercise Enhancement	-	+	+
Reflexes	N	↓	↓
Anticholinergic Sx	-	+	++
Sensory Sx	-	-	-
Associated Conditions	Thymoma	Small cell carcinoma	GI S&S
Repetitive EMG Stimulation	Decremental response	Incremental response	↑ (rapid stimulation) ↓ (slow stimulation)

Myasthenia Gravis

Etiology and Pathophysiology

- progressive autoimmune disorder due to anti-AChR or anti-MuSK antibodies, resulting in early saturation at the NMJ and inadequate muscle activation with increasing nerve stimulation
- 15% of patients with MG have associated thymic neoplasia, 85% have thymic hyperplasia

Epidemiology

- bimodal age of onset – 20s (mostly women) and 60s (mostly men)

Clinical Features

- fatigable, symmetric or asymmetric weakness without reflex changes, sensory changes, or coordination abnormalities
- ocular (diplopia/ptosis), bulbar (dysarthria/dysphagia), and/or proximal limb weakness
- symptoms may be exacerbated by infection, pregnancy, menses, and various drugs
- respiratory muscle weakness may lead to respiratory failure

Investigations

- edrophonium (Tensilon®) test - assess for improvement over 2 min following edrophonium injection
- EMG
 - repetitive stimulation → decremental response
 - single fibre electromyography shows increased jitter (80-100% sensitivity)
- spirometry – forced vital capacity may be used to monitor adequacy of respiratory effort over time
- anti-AChR antibody assay (70-80% sensitivity); anti-MuSK antibody may be used if seronegative for anti-AChR antibody
- CT/MRI to screen for thymoma/thymic hyperplasia

Neuromuscular Junction Disease
Diseases of the neuromuscular junction typically feature prominent fatigability. Fatigability can be tested by holding the arms out or by holding the gaze in the upward position (especially in MG). Muscle weakness due to fatigability will improve with rest or ice.

Figure 23. Myasthenia gravis

Treatment

- thymectomy - 85% of patients show improvement or remission
- symptomatic relief
- acetylcholinesterase inhibitors (e.g. pyridostigmine) - does not affect primary pathologic process so rarely results in control of disease when used alone
- immunosuppression
- steroids are mainstay of treatment (70-80% remission rate) - azathioprine, cyclophosphamide, and mycophenolate as adjuncts or as steroid sparing therapy
- short-term immunomodulation (for crises) - IVIG and plasmapheresis

Prognosis

- 30% eventual spontaneous remission
- with treatment, life expectancy is equal to that of a person without MG, but quality of life may vary

Lambert-Eaton Myasthenic Syndrome

Etiology and Pathophysiology

- autoimmune disorder due to antibodies against presynaptic voltage-gated calcium channels, causing decreased ACh release at the NMJ
- 50-66% are associated with small cell carcinoma of the lung

Clinical Features

- weakness of skeletal muscles without sensory or coordination abnormalities, proximal and lower muscles more affected
- reflexes are diminished or absent, but increase after active muscle contraction
- bulbar and ocular muscles affected in 25% (vs. 90% in MG)
- prominent anticholinergic autonomic symptoms (dry mouth > impotence > constipation > blurred vision)

Investigations

- edrophonium test → no response
- EMG
 - rapid (>10 Hz) repetitive stimulation → incremental response
 - post-exercise facilitation → an incremental response with exercise
- screen for malignancy, especially small cell lung cancer

Treatment

- tumour removal
- acetylcholine modulation
 - increased acetylcholine release (3,4-diaminopyridine)
 - decreased acetylcholine degradation (pyridostigmine)
- immunomodulation - steroids, plasmapheresis, IVIG

Botulism

Etiology and Pathophysiology

- caused by a toxin produced by spores of *Clostridium botulinum* bacteria, which can enter through wounds or by ingestion
- infantile botulism is the most common form, and is usually from ingestion of honey or corn syrup

Clinical Features

- occur 6-48 h after ingestion
- CN paralysis: ptosis, extraocular muscle weakness, dilated poorly reactive pupils, dysarthria, jaw weakness, dysphagia
- autonomic dysfunction: nausea, orthostatic hypotension, constipation (paralytic ileus), bladder distension
- anticholinergic symptoms: dry mouth, constipation, urinary retention
- spreads to trunk and limbs: symmetric weakness with paralysis and absent/decreased deep tendon reflexes
- pattern of paresis often starts with GI symptoms, then extraocular muscle weakness, then dysphagia, then limbs and respiratory involvement; all associated with dry mouth.
- rarely respiratory distress, potentially advancing to respiratory failure

Investigations

- blood test for toxin, stool culture
- CT/MRI to rule out stroke, lesion (normal in botulism)

Treatment

- botulinum anti-toxin – good prognosis with prompt treatment
- supportive therapy as required

Tensilon® is a drug that inhibits acetylcholinesterase. It improves muscle function immediately in myasthenia gravis, but not in a cholinergic crisis. This test is infrequently used; when performed, a crash cart should be nearby as respiratory difficulty and/or bradycardia may occur.

Figure 24. Lambert-Eaton myasthenic syndrome (LEMS)

Myopathies

Clinical Approach to Muscle Diseases

Table 20. Myopathies

	Etiology	Key Clinical Features	Key Investigations
Inflammatory	Polymyositis (see Rheumatology, RH15)	Myalgias Pharyngeal involvement	↑ CK Biopsy: endomysial infiltrates; necrosis
	Dermatomyositis (see Rheumatology, RH15)	Myalgias Characteristic rashes Can be paraneoplastic	↑ CK Biopsy: perifascicular atrophy
	Sarcoidosis	See Respirology, R14	ACE level Biopsy: granulomas
	Inclusion body myositis	Weak quadriceps and deep finger flexors	↑ CK Biopsy: inclusion bodies
Endocrine	Thyroid (↑ or ↓) Cushing's syndrome Parathyroid (↑ or ↓)	See Endocrinology, E32	TSH, serum cortisol, calcium panel
Toxic	Medication	Medication or toxin history	Toxicology screen
	Critical illness myopathy	ICU patient Hx steroids and nondepolarizing paralyzing agents Failure to wean from ventilation	Biopsy: selective loss of thick myosin filaments
Infectious	Parasitic, bacterial, or viral	Myalgias Inflammatory myopathy	↑ myoglobin
Hereditary Dystrophy	Duchenne (see Medical Genetics, MG7)	Early onset (Duchenne and Becker)	Dystrophin analysis: absent
	Becker	Progressive proximal muscle weakness Calf pseudohypertrophy	Dystrophin analysis: abnormal
	Myotonic dystrophy	Distal myopathy Myotonia Genetic anticipation	Genetic testing
Hereditary Metabolic	McArdle's	Exercise-related myalgias, cramping, and myoglobinuria	↑ lactate ↑ serum/urinary myoglobin post-exercise
Hereditary Periodic Paralysis	"Channelopathy"	Episodic weakness Normal between attacks	Normal, ↑ or ↓ K ⁺
Hereditary Mitochondrial	MERRF	Myoclonus, generalized seizures, dementia, myopathy	Biopsy: ragged red fibres Increased lactate
	MELAS	Pediatric onset, stroke-like symptoms, episodic vomiting, dementia	
	Keams Sayre	Progressive ophthalmoplegia, retinal pigment degeneration, cardiac conduction abnormalities	

MELAS = mitochondrial encephalomyopathy, lactic acidosis, and stroke-like episodes; MERRF = mitochondrial encephalomyopathy with ragged red fibres

Myopathies are characterized by prominent symmetric proximal weakness and absent sensory changes

Good Questions to Assess Proximal Weakness

- Legs: climbing stairs, stand from sit
- Arms: reach above head, wash hair

Common Medications that Cause Myopathy: steroids, statins, anti-retrovirals, thyroxine, fibrates, cyclosporine, ipecac
Common Drugs that Cause Myopathy: ethanol, cocaine, heroin

Myotonic Dystrophy

Etiology and Pathophysiology

- unstable trinucleotide (CTG) repeat in DMK gene (protein kinase) at 19q13.3, number of repeats correlates with severity of symptoms, autosomal dominant

Epidemiology

- most common adult muscular dystrophy, prevalence 3-5/100,000

Clinical Features

- appearance: ptosis, bifacial weakness, frontal baldness (including women), triangular face giving a drooping/dull appearance
- physical exam
 - distribution of weakness: distal weaker than proximal (in contrast to other myopathies), steppage gait
 - myotonia: delayed relaxation of muscles after exertion (elicit by tapping on thenar muscles with hammer)
 - cardiac: 90% have conduction defects (1° heart block; atrial arrhythmias)
 - respiratory: hypoventilation 2° to muscle weakness
 - ocular: subcapsular cataracts, retinal degeneration, decreased intraocular pressure
 - other: DM, infertility, testicular atrophy
 - EMG: subclinical myotonia – long runs with declining frequency and amplitude

Treatment and Prognosis

- no cure, progressive, death usually around 50 yr
- management of myotonia: phenytoin

Pain Syndromes

Approach to Pain Syndromes

Definitions

- nociceptive pain:** pain arising from normal activation of peripheral nociceptors
- neuropathic pain:** pain arising from direct injury to neural tissue, bypassing nociceptive pathways
- spontaneous pain:** unprovoked burning, shooting, or lancinating pain
- paresthesia:** spontaneous abnormal non-painful sensation (e.g. tingling)
- dysesthesia:** evoked pain with inappropriate quality or excessive quantity
- allodynia:** a dysesthetic response to a non-noxious stimulus
- hyperalgesia:** an exaggerated pain response to a noxious stimulus

Non-Pharmacological Management

- physical (PT, acupuncture, chiropractic manipulation, massage)
- psychoeducational (CBT, family therapy, education, psychotherapy)

Medical Pain Control

- combination multi-modal therapy is important
- primary analgesics: acetaminophen, NSAIDs (often used for soft tissue injuries, strains, sprains, headaches, and arthritis), opiates
- adjuvants: antidepressants (TCAs, SSRIs), anticonvulsants (gabapentin, carbamazepine, pregabalin), baclofen, sympatholytics (phenoxybenzamine), α 2-adrenergic agonists (clonidine)

Surgical Pain Control

- peripheral ablation: nerve blocks, facet joint denervation
- direct delivery: implantable morphine pump
- central ablation: stereotactic thalamotomy, spinal tractotomy, or dorsal root entry lesion
- DBS or dorsal column stimulation

Neuropathic Pain

Definition

- pain resulting from a disturbance of the central or peripheral nervous system

Epidemiology

- affects up to 6% of people (2 million Canadians)

- Pinprick sensation mediated by A δ fibres
- Pain due to tissue damage is mediated by C fibres

WHO Pain Ladder

- Mild Pain:** Non-opioid (acetaminophen and/or NSAID) \pm adjuvant
- Moderate Pain:** Opioid for mild to moderate pain (codeine/oxycodone) + non-opioid \pm adjuvant
- Severe Pain:** Opioid for moderate to severe pain (morphine/hydromorphone) + non-opioid \pm adjuvant

Axonal regeneration is directed by intact nerve sheaths; if the nerve sheath is damaged, axons grow without direction, become tangled and form a neuroma, which can result in ectopic electrical impulses and neuropathic pain

Symptoms and Signs

- hyperalgesia/allodynia
- subjectively described as burning, heat/cold, pricking, electric shock, perception of swelling, numbness
- can be spontaneous or stimulus evoked, distribution may not fall along classical neuro-anatomical lines
- associated issues: sleep difficulty, anxiety/stress/mood alteration

Causes of Neuropathic Pain

- **sympathetic:** complex regional pain syndrome
- **non-sympathetic:** damage to peripheral nerves
 - **systemic disease:** DM, thyroid disease, renal disease, rheumatoid arthritis, multiple sclerosis
 - **nutritional/toxicity:** alcoholism, pernicious anemia, chemotherapy
 - **infectious:** post-herpetic, HIV
 - **trauma/compression:** nerve entrapment, trigeminal neuralgia, post-surgical, nerve injury, cervical/lumbar radiculopathy, plexopathy
- **central:** abnormal CNS activity
 - phantom limb, post spinal cord injury, post stroke, MS

Treatment

- identify/treat underlying cause
- **pharmacotherapy**
 - Stepwise approach (Canadian Pain Society, 2014)
 - ♦ 1st line: Gabapentinoids, TCA, SNRI
 - ♦ 2nd line: Tramadol, opioid analgesics
 - ♦ 3rd line: Cannabinoids
 - ♦ 4th line: topical lidocaine (second line for postherpetic neuralgia), methadone, lamotrigine, lacosamide, tapentadol, botulinum toxin
- **common non-pharmacologic therapies**
 - neuropsychiatry: CBT, psychotherapy
 - rehabilitation: physiotherapy
- **surgical therapies:** dorsal column neurostimulator, DBS (thalamus)

Trigeminal Neuralgia

Clinical Features

- recurrent episodes of sudden onset, excruciating unilateral paroxysmal shooting “electric” pain in trigeminal root territory (V3>V2>>V1)
- may have normal sensory exam
- pain lasts seconds/minutes over days/weeks; may remit for wk/mo
- triggers: touching face, eating, talking, cold wind, shaving, applying make-up

Etiology

- classic TN: idiopathic
- secondary TN: compression by tortuous blood vessel (superior cerebellar artery), cerebellopontine angle tumour (5%), MS (5%)

Epidemiology

- F>M; usually middle-aged and elderly

Diagnosis

- clinical diagnosis
- investigate for secondary causes, which are more likely if bilateral TN or associated sensory loss
 - MRI to rule out structural lesion, MS, or vascular lesion

Treatment

- first line: carbamazepine or oxcarbazepine
- second line: baclofen or lamotrigine
- narcotics not generally recommended
- if medical treatment fails: trigeminal ganglion percutaneous technique, gamma knife, invasive percutaneous denervation (radiofrequency/glycerol), percutaneous balloon microcompression, microvascular decompression

Postherpetic Neuralgia

Clinical Features

- pain persisting in the region of a cutaneous outbreak of herpes zoster
- constant deep ache or burning, intermittent spontaneous lancinating/jabbing pain, allodynia
- distribution: thoracic, trigeminal, cervical > lumbar > sacral
- associated impaired sleep, decreased appetite, decreased libido

Herpes Zoster of Trigeminal Nerve

Typically involves V1 (ophthalmic division)

Hutchinson's Sign

Tip of nose involvement predicts corneal involvement

Etiology and Pathogenesis

- destruction of the sensory ganglion neurons (e.g. dorsal root, trigeminal, or geniculate ganglia) secondary to reactivation of herpes zoster infection

Epidemiology

- incidence in those with zoster increases with age (2% in <60 yr, 19% in >70 yr)
- risk factors: older age, greater acute pain, greater rash severity

Prevention

- varicella zoster vaccine (Varivax®) in childhood reduces incidence of varicella zoster
- herpes zoster vaccine (Zostavax®) reduces incidences of shingles, PHN, and other herpetic sequelae (currently recommended in Canada for those >60 yr old)

Treatment

- medical: TCA (i.e. amitriptyline), anti-convulsants (i.e. pregabalin, gabapentin), analgesia (i.e. opiates, lidocaine patch), intrathecal methylprednisolone, topical capsaicin
 - early treatment of acute herpes zoster with antivirals (acyclovir; longer-acting famciclovir and valacyclovir more effective)
 - treatment of herpes zoster with corticosteroids DOES NOT decrease PHN
- surgical: spinal tractotomy, dorsal root entry zone lesion, DBS of thalamus

Painful Diabetic Neuropathy

- see [Endocrinology, E13](#)

Approach

- determine if pain is neuropathic or vascular
- more likely neuropathic if pain present at rest and improves with walking, pain is sharp/tingling, more in feet than calves

Treatment

- Level A: pregabalin
- Level B: venlafaxine, duloxetine, amitriptyline, gabapentin, valproate, rarely opioids, capsaicin

Complex Regional Pain Syndromes

Clinical Features

- presence of an initiating noxious event (MI, stroke)
- continuing pain, allodynia, or hyperalgesia with pain disproportionate to inciting event
- evidence during the course of symptoms of edema, changes in skin blood flow or abnormal vasomotor activity
- absence of conditions that would otherwise account for degree of pain and dysfunction
- other features can include edema, osteoporosis, hyperhidrosis, hair loss, fascial thickening

Classification

- CRPS type I (reflex sympathetic dystrophy): minor injuries of limb or lesions in remote body areas precede onset of symptoms
- CRPS type II (causalgia): injury of peripheral nerves precedes the onset of symptoms

Investigations

- trial of differential neural blockade may be helpful in diagnosis
- autonomic testing (evidence of sympathetic dysfunction)
- bone scan, plain radiography, MRI

Prevention

- early mobilization after injury/infarction

Treatment

- goal of treatment: to facilitate function
- conservative treatment: education, support groups, PT/OT, smoking cessation
- medical: topical capsaicin, TCA, NSAID, tender point injections with corticosteroid/lidocaine, gabapentin/pregabalin/lamotrigine, calcitonin or bisphosphonates, oral corticosteroids
- surgical: paravertebral sympathetic ganglion blockade
- refer to pain management clinic

Headache

• see [Emergency Medicine, ER23](#) and [Family Medicine, FM32](#)

Clinical Approach

- history**
 - pain characteristics: onset, frequency, duration, intensity, location, radiation, other specific features (e.g. worse in AM, worse with bending/cough/Valsalva)
 - associated symptoms: visual changes, change in mental status, nausea/vomiting, fever, meningismus, photophobia, phonophobia, TMJ popping/clicking, jaw claudication, neurological symptoms
 - precipitating/alleviating factors (triggering factors, analgesics), medications (especially nitrates, CCBs, NSAIDs, anticoagulants), PMH, FHx
 - red flags (possible indications for CT scan/further investigation): new-onset headache (especially if age <5 or >50), quality worse/different than previous headaches, sudden and severe ('thunderclap'), immunocompromised, fever, focal neurological deficits, trauma
- physical exam**
 - vitals (including BP and temp), Kernig's/Brudzinski's, MSK examination of head and neck
 - HEENT: fundi (papilledema, retinal hemorrhages), red eye, temporal artery tenderness, sinus palpation, TMJ
 - full neurological exam (including LOC, orientation, pupils (symmetry), and focal neurological deficits)
 - red flags: papilledema, altered LOC, fever, meningismus, focal neurological deficits, signs of head trauma

Classification

- primary
 - tension, migraine, cluster, other autonomic cephalgias, SUNCT
- secondary
 - cervical OA, TMJ syndrome, SAH, ICH, stroke, venous sinus thrombosis, meningitis/encephalitis, trauma, increased ICP (space-occupying lesion, malignant HTN or pseudotumour cerebri), temporal arteritis, sinusitis, acute-angle closure glaucoma, pre-eclampsia, post LP, drugs/toxins (e.g. nitroglycerin use and analgesia withdrawal); all can be associated with serious morbidity or mortality

Table 21. Headaches – Selected Primary Types

	Tension-Type	Migraine	Cluster
Prevalence	70%	~10-20%	<1%
Age of Onset	15-40	10-30	20-40
Sex Bias	F>M	F>M	M>F
Family History	None	+++	+
Location	Bilateral frontal Nuchal-occipital	Unilateral > bilateral Fronto-temporal	Retro-orbital
Duration	Minutes – days	Hours – days	10 min-2 h
Onset/Course	Gradual; worse in PM	Gradual; worse in PM	Daily attacks for weeks to months; more common early AM or late PM
Quality	Band-like; constant	Throbbing	Constant, aching, stabbing
Severity	Mild-moderate	Moderate-severe	Severe (wakes from sleep)
Triggers/Provoking	Depression Anxiety Noise Hunger Sleep deprivation	Noise/light Caffeine/alcohol Hunger Stress Sleep deprivation	Light EtOH
Palliating	Rest	Rest	Walking around
Associated Sx	No vomiting No photophobia	Nausea/vomiting Photo/phonophobia Aura	Red watery eye Nasal congestion or rhinorrhea Unilateral Horner's
Management	Non-pharmacological Psychological counselling Physical modalities (e.g. heat, massage) Pharmacological Simple analgesics Tricyclic antidepressants	Acute Rx ASA NSAIDs Triptans Ergotamine Prophylaxis TCA Anticonvulsants Propranolol	Acute Rx O ₂ Sumatriptan (nasal or injection) Prophylaxis Verapamil Lithium Methysergide Prednisolone

If CT is negative but clinically there is suspicion of SAH or meningitis, perform an LP

Headache DDX

ER VISIT

- Eye (acute angle closure glaucoma, sinusitis)
- Recurrent/Chronic (migraine, tension, cluster, TMJ disease, cervical OA)
- Vascular (SAH, ICH, temporal arteritis)
- Infectious (meningitis, encephalitis)
- Systemic (anemia, anoxia, CO, pre-eclampsia)
- ICP (mass/abscess, HTN encephalopathy, pseudotumour cerebri)
- Trauma (concussion, SDH, EDH)

Acute and Preventive Pharmacologic Treatment of Cluster Headache

Neurology 2010;75:463-73
Study: Meta-analysis of prospective, double-blind, RCTs of pharmacologic agents for prevention or treatment of CH.
Results: 27 trials were included. Sumatriptan 6 mg SC, zolmitriptan nasal spray 5-10 mg, and 100% oxygen 6-12 L/min received Level A recommendation for acute treatment. For prevention, Level B recommendations were given for intranasal civamide 100 µg daily and suboccipital steroid injections.
Conclusion: Sumatriptan, zolmitriptan, and mid flow oxygen are effective acute treatments for CH.

Antiepileptics in Migraine Prophylaxis: An Updated Cochrane Review

Cephalalgia 2015;35:51-62
Purpose: To review the evidence for anticonvulsants in migraine prophylactics.
Study: Systematic meta-analysis of 37 published and 3 unpublished prospective, controlled trials of regular use of anticonvulsants to prevent migraines and or improve quality of life related to migraines.
Results: Sodium valproate and topiramate were associated with a reduction of 4 and 1 days of headache per month, respectively, and patients taking either drug were more than two times as likely to experience greater than 50% reduction in headache frequency, versus placebo. Neither drug was associated with undue rates of adverse events, though higher doses of topiramate were associated with increased adverse events. There is insufficient evidence of efficacy other antiepileptic drugs, including gabapentin, for migraine prophylaxis.
Conclusions: Daily sodium valproate 400 mg and topiramate 50 mg are well tolerated and effective in prophylactic treatment of migraine headache in adults.

Table 22. Prophylactic Management of Migraine Headaches

Class	Drug	Evidence	Contraindications	Side Effects
Beta-blockers	Propranolol	A	Asthma, DM (mask hypoglycemia)	Fatigue
	Timolol	A	CHF	Depression
	Metoprolol	B		Light-headedness
TCA	Amitriptyline	A	Heart disease, glaucoma	Sedation
	Nortriptyline	C	*Avoid in elderly	Dry mouth Weight gain Light-headedness
CCBs	Flunarizine	A	Depression, obesity	Weight gain, depression, PD (rare)
	Verapamil	B	Heart disease	Weight gain (4.5-9 kg), constipation
AED	Valproate	A	Liver, renal, pancreatic disease	Weight gain, tremor, alopecia, teratogenic: neural tube defect
	Topiramate + folic acid supplement	A	Renal disease	Paresthesia, weight loss, cognitive: memory loss, difficulty concentrating, renal stone (rare)

Table 23. Headaches – Selected Serious but Rare Secondary Types

	Meningeal Irritation	Increased ICP	Temporal Arteritis
Age of Onset	Any age	Any age	>60 yr
Location	Generalized	Any location	Temporal
Onset/Course	Meningitis: hours-days		
SAH: thunderclap onset	Gradual; worse in AM	Variable	
Severity	Severe	Severe	Variable; can be severe
Provoking	Head movement	Lying down Valsalva Head low Exertion	Jaw claudication
Associated Sx	Neck stiffness Photophobia Focal deficits (e.g. CN palsies)	N/V Focal neuro symptoms Decreased level of consciousness	Polymyalgia rheumatica Visual loss
Physical Signs	Kernig’s sign Brudzinski’s sign Meningismus	Focal neuro symptoms Papilledema	Temporal artery changes: Firm, nodular, incompressible Tender
Management	CT/MRI with gadolinium LP, antibiotics for bacterial meningitis	CT/MRI and treatment to reduce pressure See Neurosurgery, NS4	Prednisone See Rheumatology, RH20
Etiology	Meningitis, SAH	Tumour, IIH, malignant HTN	Vasculitis (GCA)

IIH = idiopathic intracranial HTN

Migraine Headaches

Definition (Common Migraine)

- ≥5 attacks fulfilling each of the following criteria
 - 4-72 h duration
 - 2 of the following: unilateral, pulsating, moderate-severe (interferes with daily activity), aggravated by routine physical activity
 - 1 of the following: nausea/vomiting, photophobia/phonophobia/osmophobia

Epidemiology

- 18% females, 6% males; frequency decreases with age (especially at menopause)

Etiology and Pathophysiology

- theories of migraine etiology
 - depolarizing wave of “cortical spreading depression” across the cerebral cortex that may cause an aura (e.g. visual symptoms due to wave through occipital cortex) and also activate trigeminal nerve afferent fibres
 - possible association with vasoconstriction/dilation
- significant genetic contribution
- **triggers:** stress, sleep excess/deprivation, drugs (estrogen, nitroglycerin), hormonal changes, caffeine withdrawal, chocolate, tyramines (e.g. red wine), nitrites (e.g. processed meats)

The oral contraceptive pill is contraindicated with complicated migraine due to risk of stroke

Migraine auras can mimic other causes of transient neurological deficits (e.g. TIAs and seizures)

“Menstrual Migraine” Subtype
Migraine headache that is associated with the onset of menstruation – usually 2 d before to 3 d after the onset of menstrual bleeding

If patient presents to ED with severe migraine and N/V – consider treating with IV anti-emetics (chlorpromazine, prochlorperazine)

Signs and Symptoms

- stages of uncomplicated migraine
 - prodrome (hours to days before headache onset)
 - aura
 - headache
 - postdrome
- aura
 - fully reversible symptom of focal cerebral dysfunction lasting <60 min
 - examples: visual disturbance (fortification spectra – zigzags; scintillating scotomata – spots), unilateral paresthesia and numbness or weakness, aphasia
- prodrome/postdrome: appetite change, autonomic symptoms, altered mood, psychomotor agitation/retardation
- classification of migraines
 - common migraine: no aura
 - classic migraine: with aura (headache follows reversible aura within 60 min)
 - complicated migraine: with severe/persistent sensorimotor deficits
 - examples: basilar-type migraine (occipital headache with diplopia, vertigo, ataxia, and altered level of consciousness), hemiplegic/hemisensory migraine, ophthalmoplegic migraine
 - acephalgic migraine (i.e. migraine equivalent): aura without headache

Treatment

- avoid triggers
- mild to moderate migraine
 - 1st line: NSAIDs (ibuprofen, naproxen)
- moderate to severe migraine
 - triptans (most effective), ergots (dihydroergotamine, DHE)
- migraine prophylaxis: anticonvulsants (divalproex, topiramate, gabapentin), TCA (amitriptyline, nortriptyline), propranolol, calcium channel blocker (verapamil)

Pharmacological Treatments for Acute Migraine Pain 2002;97:247-257

Study: Meta-analysis of 54 double-blind, placebo-controlled RCTs of pharmacologic treatment of acute migraine of moderate to severe intensity (21,022 patients in total).

Data Extraction: Number of patients, dosing regimens, details of study design, and timing or type of rescue medication. Outcomes include headache relief at 1 and 2 h, freedom from pain at 2 h, sustained relief for 24 h, and adverse effects within 24 h.

Main Results: Data were available for 9 oral medications, 2 intranasal medications, and subcutaneous sumatriptan. For H/A relief at 2 h, all interventions were effective except Cafergot®, with NNTs ranging from 2.0 for sumatriptan 6 mg SC to 5.4 for naratriptan 2.5 mg. The lowest NNT for oral medication was 2.6 for eletriptan 80 mg. For patients pain free at 2 h, the lowest NNT was 2.1 for sumatriptan 6 mg SC, with the lowest NNT for oral medication being 3.1 for rizatriptan 10 mg. For sustained relief over 24 h NNT ranged from 2.8 for eletriptan 80 mg to 8.3 for rizatriptan 5 mg. Side effects could not be analyzed systematically. There were no drug-to-drug comparisons.

Conclusion: Overall, most treatments were effective. Subcutaneous sumatriptan and oral triptans were most effective.

Elements of Sleep History

- Initiation of sleep
- Events prior to bed
- Lights
- Latency (estimated)
- Restless legs
- Hallucinations
- Maintaining sleep
- Number of wakeups/night
- Sleep walking/talking
- Snoring/gasping
- Dreams/nightmares
- Consequences of sleep
- Restorative
- Morning headache
- Falling asleep in inappropriate setting

Sleep Disorders

Overview of Sleep

Definition

- newborn: 18 h sleep (50% REM), adolescents: 10 h, adults: 7-9 h but most get insufficient amounts
- many elderly have reduced sleep as a consequence of underlying sleep disorders

Sleep Architecture

- polysomnogram (PSG) measures:** EEG, eye movements (electro-oculogram – EOG), EMG, respiratory effort, oxygenation, ECG

Table 24. Sleep Stage Characteristics

	EEG	EOG	Muscle Tone	Other Characteristics
Waking State	Alpha waves: high frequency (8-12 Hz), low voltage	Rapid, blinking	High	
Stage N1 (~5%)	Less than 50% Alpha waves (see above), mixed with slow wave activity	Slow, roving eye movements	High, but gradually dropping	Marker for very light quality sleep or sleep disruption
Stage N2 (~50%)	K complexes (high voltage negative and positive discharges) with sleep spindles (11-16 Hz)	Still	High	
Stage N3 (previously 3 and 4)/Slow Wave/Delta Sleep (~20%)	Delta waves: low frequency (<2 Hz), high voltage (>75 µV)	Still	Low	Homeostatic sleep Reduced BP, HR, cardiac output, RR Growth hormone release
Rapid Eye Movement (REM) Sleep (~25%)	Sawtooth waves, mixed frequency, low voltage	Rapid eye movements	Very low	Irregular respiration Arrhythmias, heart rate variation Classical dreaming state

Disturbances of Alertness and Sleep

Coma

- see [Neurosurgery, NS35](#)

Insomnia

- difficulty initiating or maintaining sleep, or waking up earlier than desired (leading to sleep that is chronically non-restorative/poor quality) despite adequate opportunity and circumstances for sleep
- **types**
 - sleep state misperception, psychophysiologic insomnia (learned sleep-preventing associations – i.e. clock watching), fatal familial insomnia (rare prion protein mutation causing autonomic dysfunction), idiopathic (lifelong difficulty)
 - **secondary causes**
 - ♦ psychiatric disorders (80% of psychiatric patients): anxiety and depression (see [Psychiatry, PS13](#))
 - ♦ neurologic disorders: neurodegenerative disease, epilepsy, neuromuscular disorders, many others
 - ♦ sleep disorders: restless legs syndrome (sleep initiation difficulties), sleep apnea (sleep maintenance difficulties)
 - ♦ medical conditions: pregnancy, cardiorespiratory (COPD/HF), GERD, pain (arthritis, fibromyalgia, cancer)
 - ♦ drugs/toxins: caffeine, alcohol, stimulants, antidepressants, glucocorticoids, sedative withdrawal
- **treatment**
 - sleep log, sleep hygiene, stimulus control, sleep restriction, relaxation response, CBT

Drug Effects on Wakefulness and Sleep

- Antihistamines associated with increased sleepiness
- Stimulants increase arousal
- Caffeine (an adenosine antagonist) increases wakefulness
- Benzodiazepines reduce slow wave sleep
- Antidepressants (TCA/MAOI/SSRI) reduce REM, prolong REM latency
- Alcohol may hasten sleep onset but associated with increased arousals

Sleep Apnea

- disorder of breathing in sleep associated with sleep disruption and consequent excessive somnolence (or drowsiness)
- **epidemiology**
 - >2-4% of the population
 - correlated with obesity
 - significant morbidity: HTN, stroke, heart failure, sleepiness, mortality (accidents)
- **types**
 - obstructive sleep apnea
 - central sleep apnea: no effort to breathe over 10 s
 - mixed apnea: starts as central, but eventually becomes obstructive
- **etiology of central apnea:** heart failure, opiates, brainstem pathology, myotonic dystrophy
- **etiology of obstructive apnea:** collapse of airway due to low muscle tone in deep and REM sleep
- **diagnosis:** apnea hypopnea index (AHI) or respiratory disturbance index (RDI) should be <5 in the normal state
- **treatment:** conservative measures, dental devices, CPAP (common), surgery (rare), ensure driving safety

Avoid sleep medications (especially in elderly patients) due to increased risk of falls, pseudodepression, and memory loss

Restless Leg Syndrome (RLS) and Periodic Limb Movement in Sleep (PLMS)

- urge to move accompanied by uncomfortable sensations that begin or worsen with rest, are partially or totally relieved with movement, and are worse in evening/night; these features cannot be accounted for by another medical/behavioural condition
- RLS refers to sensation
- PLMS refers to the manifestation
- **epidemiology:** 10% North Americans, 90% of RLS have PLMS, 50% of patients with PLMS have RLS
- **etiology:** central (spasticity), peripheral nervous system (radiculopathy, neuropathy), pregnancy, iron deficiency, alcohol use
- **treatment**
 - underlying contributors (iron and B12 supplementation), dopaminergic agonists (first line), clonazepam (causes tachyphylaxis), opioids (only exceptional circumstances)
 - NOT recommended: levodopa/carbidopa (Sinemet®), causes augmentation

Narcolepsy

- **definition/clinical features:** excessive daytime sleepiness (all narcolepsy), cataplexy = loss of muscle tone with emotional stimuli (pathognomonic), sleep paralysis (unable to move upon waking), hypnagogic hallucinations (vivid dreams or hallucinations at sleep onset)
- **epidemiology:** prevalence 1:2,000, onset in adolescence/early adulthood; life-long disorder
- **etiology:** presumed autoimmune attack on orexin/hypocretin system, post head injury, MS, hypothalamic tumours; rarely familial
- **diagnosis:** based on clinical history + multiple sleep latency test findings of short sleep latency <8 min and REM within 15 min of sleep onset on 2/4 naps
- **treatment**
 - sleep hygiene and scheduled brief naps, restricted driving
 - alerting agents: modafinil (non-amphetamine stimulant), stimulant (i.e. methylphenidate)
 - anticataplectic: TCAs, SSRIs, sodium oxybate

Parasomnias

- **definition/clinical features:** unusual behaviours in sleep with clinical features appropriate to stage of sleep
- **etiology:** in elderly, REM sleep behaviour disorder may be associated with PD; in children, slow wave sleep arousals (sleep walking) may be associated with sleep disordered breathing
- **diagnosis:** clinical history in children, polysomnography in adults to exclude nocturnal seizures
- **treatment:** behavioural management (safety, adequate sleep); clonazepam for REM sleep behaviour, tonsillectomy if appropriate in children

Circadian Rhythm

- **definition/clinical features:** abnormalities based on time of day rather than sleep (i.e. jet lag, shift work)
- **diagnosis:** clinical history

CNS Infections

- see [Infectious Diseases, ID18](#)

Spinal Cord Syndromes

- see [Neurosurgery, NS29](#)

Stroke

Terminology

- **stroke:** sudden onset of neurological deficits of a vascular basis with infarction of CNS tissue
 - infarction is permanent tissue injury (confirmed by neuroimaging)
- **TIA:** sudden onset of neurological deficits of a vascular basis without infarction (i.e. no imaging evidence of stroke)
 - may present with amaurosis fugax (transient monocular painless vision loss)

Hypertension Encephalopathy

Acute severe HTN (typically dBP > 130 or sBP > 200) can cause hypertensive encephalopathy – abnormal fundoscopic exam (papilledema, hemorrhages, exudates, cotton-wool spots), focal neurological symptoms, IV/V, visual disturbances, and change in LOC

Pathophysiology

- two major types: ischemic (~80%) and hemorrhagic (~20%)

1. ischemic

- arterial thrombosis: thrombus formation in artery (local/in situ)
 - ♦ large vessel: stenosis or occlusion of the internal carotid artery, vertebral, or intracranial arteries
 - mechanism: insufficient blood flow beyond lesion (hemodynamic stroke)
 - underlying processes: atherosclerosis (most common cause), dissection, and vasculitis
 - ♦ small vessel/lacunar
 - mechanism: chronic HTN and DM cause vessel wall thickening and decreased luminal diameter
 - affects mainly small penetrating arteries (primarily basal ganglia, internal capsule, and thalamus)
- cardioembolic: blockage of cerebral arterial blood flow due to particles originating from a cardiac source
 - ♦ atrial fibrillation (most common), rheumatic valve disease, prosthetic heart valves, recent MI, fibrous and infectious endocarditis
- systemic hypoperfusion (global cerebral ischemia)
 - ♦ inadequate blood flow to brain, usually secondary to cardiac pump failure (e.g. cardiac arrest, arrhythmia, or MI)
 - ♦ primarily affects watershed areas (between the major cerebral arterial territories)

Consider transfer of acute stroke patient to a designated stroke centre for neuroprotective or thrombolytic therapy if the patient is seen in first few hours

Early seizure activity occurs in 5-25% of patients after ICH

Cerebral venous sinus thrombosis should be considered in the differential diagnosis of stroke and headache. It is an uncommon cause of either, but is associated with high morbidity and mortality. Patients often present with headache alone, but can also have seizures, focal neurological deficits, or cranial nerve palsies. This is diagnosed with MRV or CTV. Treatment is typically anticoagulation with heparin initially, then transition to warfarin

2. hemorrhagic

- intracerebral hemorrhage
 - ♦ mechanisms
 - hypertensive (most common): rupture of small microaneurysms (Charcot-Bouchard aneurysms) causing intraparenchymal hemorrhage; most common sites: putamen, thalamus, cerebellum, and pons
 - other: trauma, amyloid angiopathy (associated with lobar hemorrhage), vascular malformations, vasculitis, drug use (cocaine or amphetamines)
- subarachnoid hemorrhage see [Neurosurgery, NS18](#)

20-40% of patients with ischemic stroke may develop hemorrhagic transformation within 1 wk after the initial infarction

Blood work should only delay treatment if: patient is on anticoagulants, low platelet count suspected, abnormal electrolytes suspected, or any bleeding abnormality suspected

Stroke Syndromes According to Vascular Territory

- **ACA:** contralateral leg paresis, sensory loss, cognitive deficits (e.g. apathy, confusion, and poor judgment)
- **MCA:** proximal occlusion involves
 1. contralateral weakness and sensory loss of face and arm
 2. cortical sensory loss
 3. may have contralateral homonymous hemianopia or quadrantanopia
 4. if dominant (usually left) hemisphere: aphasia
 5. if non-dominant (usually right) hemisphere: neglect
 6. eye deviation towards the side of the lesion and away from the weak side
- **PCA**
 1. contralateral hemianopia or quadrantanopia
 2. midbrain findings: CN III and IV palsy/pupillary changes, hemiparesis
 3. thalamic findings: sensory loss, amnesia, decreased level of consciousness
 4. if bilateral: cortical blindness or prosopagnosia
 5. hemiballismus
- **basilar artery**
 - proximal (usually thrombosis): impaired EOM, vertical nystagmus, reactive miosis, hemi- or quadriplegia, dysarthria, locked-in syndrome, coma
 - distal (usually embolic, i.e. top of the basilar syndrome): somnolence, memory and behaviour abnormalities, oculomotor deficit
- **PICA (lateral medullary or Wallenberg syndrome):** ipsilateral ataxia, ipsilateral Horner's, ipsilateral facial sensory loss, contralateral limb impairment of pain and temperature sensation, nystagmus, vertigo, nausea/vomiting, dysphagia, dysarthria, hiccups
- **medial medullary infarct** (anterior spinal artery, which can be associated with anterior cord infarct): contralateral hemiparesis (facial sparing), contralateral impaired proprioception and vibration sensation, ipsilateral tongue weakness
- **lacunar infarcts** (deep hemispheric white matter; involving deep penetrating arteries of MCA, circle of Willis, basilar, and vertebral arteries)
 - pure motor hemiparesis (posterior limb of internal capsule): contralateral arm, leg, and face
 - pure sensory loss (ventral thalamic): hemisensory loss
 - ataxic hemiparesis (ventral pons or internal capsule): ipsilateral ataxia and leg paresis
 - dysarthria-clumsy hand syndrome (ventral pons or genu of internal capsule): dysarthria, facial weakness, dysphagia, mild hand weakness and clumsiness

Stroke mimics: drug intoxication, infections, migraines, metabolic, seizures, tumours

Suspect an alternate diagnosis if: fever, decreased LOC, fluctuating symptoms, gradual onset, no focal neurological symptoms, and/or positive symptoms

Infarcted area of brain tissue can often appear normal on CT during the first several hours after the onset of stroke

Oral Direct Thrombin Inhibitors or Oral Factor Xa Inhibitors for the Treatment of Deep Vein Thrombosis

Cochrane DB Syst Rev 2015;6:CD010956
Purpose: To assess whether DTIs or factor Xa inhibitors are effective treatment for DVTs.
Study: Systematic review search 1950-2015, inclusive. Results included 11 RCTs, 27,945 patients, comparing DTIs or factor Xa inhibitors to standard treatment (heparin, warfarin, and similar).
Outcome: Recurrent DVT or PE.
Results: Separate meta-analyses of DTIs and factor Xa inhibitors showed that each was comparable to standard treatment in terms of DVT recurrence rates. Rates of fatal or non-fatal PE, and all-cause mortality were also not significantly different. Additionally, factor Xa inhibitors had lower rates of bleeding complications than standard treatment (OR 0.57; CI 0.43 to 0.76).
Conclusions: New oral treatment options, including direct thrombin inhibitors and factor Xa inhibitors represent reasonable and safe alternatives for acute.

The National Institute of Health Stroke Scale (NIHSS) is a standardized clinical examination that determines the severity of an acute stroke; it can also be used to monitor response to treatment over time. The scale uses 11 items that evaluate:

- Level of consciousness
- Visual system
- Motor system
- Sensory system
- Language abilities

Scoring (x/42):
 0=no stroke
 1-4=mild stroke
 5-15=moderate stroke
 15-20=moderate to severe stroke
 21-42=severe stroke

rTPA is typically considered if score ≥ 6 , but some stroke neurologists will administer rTPA with lower NIH stroke scale scores

Figure 25. Vascular territories

Assessment and Treatment of Ischemic Stroke

General Assessment

- ABCs, full vital sign monitoring, capillary glucose (Accu-Chek[®]), urgent CODE STROKE if <4.5 h from symptom onset (for possible thrombolysis)
- level of consciousness (knows age, month, obeys commands), dysarthria, dysnomia (cannot name objects)
- gaze preference, visual fields, facial palsy
- arm drift, leg weakness, ataxia
- sensation to pinprick, extinction/neglect
- **history**
 - onset: time when last known to be awake and symptom free
 - mimics to rule out: seizure/post-ictal, hypoglycemia, migraine, conversion disorder
- **investigations**
 - non-contrast CT head (STAT): to rule out hemorrhage and assess extent of infarct
 - ECG: to rule out atrial fibrillation (cardioembolic cause)
 - carotid dopplers, echocardiogram
 - CBC, electrolytes, creatinine, PTT/INR, blood glucose, lipid profile
- **imaging** (i.e. CT ± MR or CT angiography) signs of stroke
 - loss of cortical white-grey differentiation
 - sulcal effacement (i.e. mass effect decreases visualization of sulci)
 - hypodensity of parenchyma
 - insular ribbon sign
 - hyperdense MCA sign

ACUTE STROKE MANAGEMENT

1. Thrombolysis

- rtPA (recombinant tissue plasminogen activator)
- given within 4.5 h of acute ischemic stroke onset provided there are clinical indications and no contraindications to use
- indications and contraindications (see sidebar)

2. Anti-Platelet Therapy

- give at presentation of TIA or stroke if rtPA not received
- antiplatelet agents
 - ASA: recommended dose 81 mg chewed
 - if patient intolerant to ASA, use other antiplatelet agent (i.e. clopidogrel)

3. Acute Anti-Coagulant Therapy

- for patients with TIA or stroke and atrial fibrillation, if rtPA not received:
 - recommend IV heparin (or ensuring INR between 2-3 if already anticoagulated on warfarin)
 - may delay initiation of oral anticoagulation depending on size of infarct and presence of petechial/frank hemorrhage

4. Intra-arterial Thrombectomy by Interventional Radiology

- early thrombectomy improves outcomes in ischemic stroke with large artery occlusions of the proximal anterior circulation

Other Acute Management Issues

- avoid hyperglycemia which can increase the infarct size
- lower temperature if febrile (febrile stroke: think septic emboli from endocarditis)
- prevent complications
 - NPO if dysphagia (to be reassessed by SLP)
 - DVT prophylaxis if bed-bound
 - initiate rehabilitation early

Blood Pressure Control

- do NOT lower the blood pressure unless the HTN is severe
- antihypertensive therapy is withheld for 48-72 hr (permissive hypertension) after thromboembolic stroke unless sBP >220 mmHg or dBP >120 mmHg, or in the setting of acute MI, renal failure, aortic dissection (IV labetalol first-line if needed)
- acutely elevated BP is necessary to maintain brain perfusion to the ischemic penumbra
- most patients with an acute cerebral infarct are initially hypertensive and their BP will fall spontaneously within 1-2 d

Etiological Diagnosis

- further investigations
 - additional neuroimaging (MRI)
 - vascular imaging: CTA/MRA/carotid dopplers
 - cardiac tests: echocardiogram, Holter monitoring
 - correct etiological diagnosis is critical for appropriate secondary prevention strategies

Aspect Score: 10-point quantitative score to assess ischemic changes on CT scan

- 10/10 is normal and <4/10 signifies high risk of bleed with rtPA
- Subtract 1 point for each of following structures if abnormal within the ischemic hemisphere: caudate, lentiform, insula, internal capsule, MCA 1, 2, 3, 4, 5, 6 regions

If rtPA given at stroke onset, delay acute antiplatelet/anticoagulation treatment by 24 h

Absolute Contraindications to rtPA

Hx: improving Sx, minor Sx, seizure at stroke onset, recent major surgery (within 14 d) or trauma, recent GI or urinary hemorrhage (within 21 d), recent LP or arterial puncture at noncompressible site, PMHx ICH, Sx of SAH/pericarditis/MI, pregnancy
P/E: sBP ≥185, dBP ≥110, aggressive treatment to decrease BP, uncontrolled serum glucose, thrombocytopenia
Ix: hemorrhage or mass on CT, high INR or aPTT

Factor Xa Inhibitors Versus Vitamin K Antagonists for Preventing Cerebral or Systemic Embolism in Patients with Atrial Fibrillation

Cochrane DB Syst Rev. 2014;8:CD008980

Purpose: To review the evidence comparing factor Xa inhibitors with vitamin K antagonists for prevention of embolic events in patients with atrial fibrillation.

Study: Systematic review search 1950-2013, inclusive. Results included 10 RCTs, 42,084 patients, follow-up for 12 weeks to 1.9 years.

Outcome: Stroke (hemorrhagic or ischemic) and non-CNS embolic event

Results: Factor Xa inhibitor treatment resulted in significantly fewer embolic events than dose adjusted warfarin treatment (OR 0.81; CI 0.72 to 0.91). There was no significant difference in rate of major bleeds between factor Xa inhibitors and warfarin treatment. Furthermore, factor Xa inhibitors resulted in significantly fewer intracranial bleeds and lower all-cause mortality.

Conclusions: Use of factor Xa inhibitor for anti-coagulation in patients with atrial fibrillation offered better protection against embolic events than warfarin. Factor Xa inhibitors also had equal or lower rates of adverse events.

High-Dose Atorvastatin after Stroke or Transient Ischemic Attack (SPARCL Trial)

NEJM 2006;355:549-559

Method: Multicentre double-blind RCT.

Population: 4,731 patients with stroke or TIA within 1-6 mo before study entry, LDL 100-190 mg/dL, no coronary heart disease.

Intervention: 80 mg atorvastatin PO OD or placebo.

Outcome: First non-fatal or fatal stroke over 5 yr. Results: Patients receiving atorvastatin had a lower rate of stroke (ARI 2.2%, hazard ratio 0.84; p=0.03). There was a five yr absolute reduction in risk of 3.5% (p=0.002). There was no significant change in mortality rate, but a small significant increase in the risk of hemorrhagic stroke.

Conclusions: High-dose atorvastatin decreases overall incidence of strokes and cardiovascular events in patients with a history of recent stroke or TIA.

Evaluating for Occult Atrial Fibrillation – CRYSTAL AF Trial

NEJM 2014;370:2478-86

Patients with a cryptogenic ischemic stroke or TIA and no evidence of atrial fibrillation on ECG and Holter monitoring may benefit from ambulatory cardiac monitoring with subcutaneous implantable loop recorder or external loop recorder for several weeks.

Primary and Secondary Prevention of Ischemic Stroke

Anti-Platelet Therapy

- primary prevention
 - no firm evidence for a protective role for antiplatelet agents for low-risk patients without a prior stroke/TIA
- secondary prevention
 - initial choice: ASA
 - if cerebrovascular symptoms while on ASA or if unable to tolerate ASA: Aggrenox® (ESPRIT trial), clopidogrel (CAPRIE trial)

Carotid Stenosis

- primary prevention (asymptomatic)
 - carotid endarterectomy is controversial: if stenosis >60%, risk of stroke is 2% per yr; carotid endarterectomy reduces the risk of stroke by 1% per yr (but 5% risk of complications)
- secondary prevention (previous stroke/TIA in carotid territory)
 - carotid endarterectomy clearly benefits those with symptomatic severe stenosis (70-99%), and is less beneficial for those with symptomatic moderate stenosis (50-69%) (NASCET trial), [see Vascular Surgery, VS6](#)
- according to the CREST trial, endarterectomy and carotid stenting have similar benefits in a composite endpoint of reduction of stroke, MI, and death; however, in the periprocedural period, stenting results in a higher rate of stroke, while endarterectomy results in a higher rate of MI

Atrial Fibrillation

- primary and secondary prevention with anticoagulation
 - classical risk stratification used CHADS₂ score (0-6), but Stroke 2014 guidelines recommend that virtually all patients with atrial fibrillation without contraindication be anticoagulated
 - ♦ 0 (low risk, 1.9% annual stroke risk): antiplatelet
 - ♦ 1 (intermediate risk, 2.8% annual stroke risk): anticoagulant or antiplatelet – patient specific decision
 - ♦ >2 (high risk, 4-18.2% annual stroke risk): anticoagulant
 - anticoagulation therapy
 - ♦ warfarin (titrate to INR 2-3)
 - ♦ dabigatran (110 or 150 mg PO bid), apixaban (2.5 or 5 mg PO bid) or rivaroxaban (15 or 20 mg PO daily) may be alternatives to warfarin, but should be used cautiously; Praxbind reversal agent for dabigatran if necessary

Hypertension

- primary prevention
 - targets: BP <140/90 (or <130/80 for diabetics or renal disease); high risk but without diabetes, target sBP < 120 (SPRINT trial)
 - ACEI: ramipril 10 mg PO OD is effective in patients at high risk for cardiovascular disease (HOPE trial)
- secondary prevention
 - ACEI and thiazide diuretics are recommended in patients with previous stroke/TIA (PROGRESS trial)

Hypercholesterolemia

- primary prevention
 - statins in patients with CAD or at high risk for cardiovascular events, even with normal cholesterol (CARE trial)
- secondary prevention
 - statins – high dose atorvastatin (SPARCL trial) but lower doses may be more appropriate if patient cannot tolerate high dose

Diabetes

- ideal management: HbA1c <7%, fasting blood glucose between 4 and 7

Smoking

- primary prevention: smoking increases risk of stroke in a dose-dependent manner
- secondary prevention: after smoking cessation, the risk of stroke decreases to baseline within 2-5 yr

Physical Activity

- beneficial effect of regular physical activity has a dose-related response in terms of intensity and duration of activity

Stroke Rehabilitation

- individualized based on severity and nature of impairment; may require inpatient program and continuation through home care or outpatient services
- multidisciplinary approach includes dysphagia assessment and dietary modifications, communication rehabilitation, cognitive and psychological assessments including screen for depression, therapeutic exercise programs, assessment of ambulation and evaluation of need for assistive devices, splints or braces, vocational rehabilitation

CHADS₂

Stroke risk stratification for patients with atrial fibrillation
 CHF (1 point)
 HTN sBP >160 mmHg/treated HTN (1 point)
 Age >75 yr (1 point)
 DM (1 point)
 Prior Stroke or TIA (2 points)

Carotid endarterectomy needs to be done within 2 wk of the ischemic event for the most benefit

ABCD² Score

To predict/identify individuals at high risk of stroke following TIA
 Age: 1 point for age >60 yr
 Blood pressure (at presentation): 1 point for HTN (> 140/90 mmHg at initial evaluation)
 Clinical features: 2 points for unilateral weakness, 1 point for speech disturbance without weakness
 Duration of symptoms: 1 point for 10-59 min, 2 points for >60 min
 DM: 1 point
 Stroke risk: 0-3: low risk, 4-5: moderate risk, 6-7: high risk

Long-Term Results of Stenting vs. Endarterectomy for Carotid-Artery Stenosis

NEJM 2016; 374:1021-1031

Study: Patients were randomly assigned to stenting or endarterectomy and assessed every 6 months for up to 10 years.

Population: 2502 patients at 117 centres with carotid-artery stenosis.

Outcome: Primary composite outcome was stroke, myocardial infarction, or death during periprocedural period or subsequent ipsilateral stroke.

Results: There was no significant difference in outcomes of either primary composite endpoint (HR 1.10; 95% CI 0.83-1.44) or post-procedural stroke (HR 0.99; 95% CI 0.64-1.52) in patients treated with stenting or endarterectomy. Asymptomatic and symptomatic patients showed no significant between-group differences in either endpoint.

Conclusions: The rate of periprocedural stroke, myocardial infarction, death, and subsequent ipsilateral stroke did not differ between carotid-artery stenosis patients treated with stenting or endarterectomy at 10 years of follow-up.

Endovascular Treatment vs. Medical Care Alone for Ischaemic Stroke: Systematic Review and Meta-Analysis

BMJ 2016;353:i1754

Purpose: To evaluate the evidence for endovascular intervention in the treatment of ischaemic stroke.

Study: Systematic review and meta-analysis of 10 randomized-controlled trials of 2,925 patients testing the efficacy and safety of adjunctive endovascular intervention in patients suffering acute, ischaemic stroke in the anterior circulation versus medical therapy, including thrombolysis, alone.

Results: The 7 RCTs published or presented in 2015 were without significant heterogeneity and formed the basis for the analysis. The majority of patients (86%) received stent retrievers and experienced higher than expected rates of recanalization (>58%). Risk ratio for good functional outcomes was 1.56 (95% CI 1.38-1.75) and 0.86 for mortality (95% CI 0.69-1.06). There was no difference in symptomatic intracranial hemorrhage following therapy.

Conclusions: Endovascular therapy is safe and improves functional outcomes when added to medical care with thrombolysis when administered within 6-8 hours of large vessel, anterior circulation ischaemic stroke. A trend towards improved mortality exists with complete follow-up results of several key trials pending.

Cerebral Hemorrhage

- **definition:** intracranial bleeding into brain tissue
- **etiology:** head trauma, hemorrhagic stroke

Investigations

- general investigations: *see Assessment and Treatment of Ischemic Stroke, N50*
- further investigations
 - LP (if suspect subarachnoid hemorrhage despite negative CT)
 - may require cerebral angiogram if suspect aneurysm or AVM
 - if typical location for hypertensive hemorrhage, repeat CT head in 4-6 wk after hemorrhage has resolved to rule out an underlying lesion

Treatment

- medical
 - anti-hypertensives: no conclusive BP target ranges for managing ICH exist; 2010 AHA/ASA guidelines suggest that reducing sBP to as low as 140 mmHg with IV anti-hypertensives is safe and appropriate management (target sBP 140-160 systolic)
 - ICP lowering medical management (if necessary): *see Neurosurgery, NS4*
- surgical: *see Neurosurgery, NS22*

Neurocutaneous Syndromes

- *see Pediatrics, P79*

Multiple Sclerosis

Definition

- a chronic inflammatory disease of the CNS characterized by relapsing remitting, or progressive neurologic symptoms due to inflammation, demyelination, and axonal degeneration

Clinical Patterns of MS

- relapsing remitting (RRMS) 85%, primary progressive (PPMS) 10%, progressive relapsing (PRMS) 5%, secondary progressive (SPMS)
- benign MS (BMS): retrospective diagnosis made after 15 years of mild disease, with no evidence of worsening (in functional ability and MRI)
- most RRMS goes on to become SPMS

MS Variants

- **Devic's = neuromyelitis optica (NMO):** severe optic neuritis and extensive transverse myelitis extending >3 vertebral segments (antibody positive)
- **clinically isolated syndrome (CIS):** single MS-like episode, which may progress to MS
- **tumefactive MS:** solitary lesion >2 cm mimicking neoplasms on MRI
- **fulminant MS (Marburg):** rapidly progressive and fatal MS associated with severe axonal damage, inflammation, and necrosis
- **pediatric MS:** onset of MS before the age of 18
 - epidemiology: rare (1.35-2.5 per 100,000 children)
 - presentation: more likely to present with isolated optic neuritis, isolated brainstem syndrome or symptoms of encephalopathy compared to adults
 - course: 98% have RRMS
 - diagnosis and treatment similar to adult MS
 - differential diagnosis: in the setting of nonspecific CSF abnormalities and MRI evidence of white matter lesion, rule out ADEM, optic neuritis, transverse myelitis, neuromyelitis optica, CNS malignancies, leukodystrophies, and mitochondrial disease
- **acute disseminated encephalomyelitis (ADEM):** monophasic demyelinating disorder with multifocal neurologic symptoms seen mainly in children often following infection or vaccination

Etiology

- genetic
 - polygenetic: the HLA-DRB1 gene has been demonstrated to be a genetically susceptible area
 - 30% concordance for monozygotic twins, 2-4% risk in offspring of affected mother or father
- environmental
 - MS is more common in regions with less sun exposure and lower stores of vitamin D (Europe, Canada, US, New Zealand, SE Australia)
 - MS has also been linked to certain viruses (EBV is associated with MS)

ACE Inhibitor in Stroke Prevention – HOPE Trial

NEJM 2000;342:145-153
Study: Randomized, blinded, placebo-controlled trial. Mean follow-up 5 yr.
Patients: 9,297 patients ≥ 55 yr (mean age 66 yr, 73% men) who had evidence of vascular disease or DM plus one other cardiovascular risk factor and who were not known to have a low ejection fraction or heart failure.
Intervention: Ramipril 10 mg daily orally vs. matching placebo.
Main Outcomes: Stroke, MI, or death from cardiovascular causes.
Results:

Outcome	RRR (95%CI)	NNT (CI)
Stroke	32% (16-44)	67 (43-145)
MI, stroke, or CV mortality	22% (14-30)	26 (19-43)
All-cause mortality	16% (5-25)	56 (32-195)

Treatment with ramipril reduced the risk of stroke (3.4% vs. 4.9%; RR 0.68; $p < 0.001$).
 Conclusions: In adults at high risk for cardiovascular events, ramipril reduced the risk of stroke, as well as other vascular events and overall mortality. In addition, ACEI reduce risk of stroke beyond their hypertensive effect.

Figure 26. Clinical patterns of MS

Most symptoms in MS are due to cord, brainstem, and optic nerve lesions

Chronic Cerebrospinal Venous Insufficiency (CCSVI)

A theory proposed in 2008 describing abnormal venous blood flow in patients with MS; while some RCTs are still underway, recent studies have largely discredited this highly controversial theory. That is, studies indicate no connection between CCSVI and MS

The Expanded Disability Status Scale (EDSS) is used as a measure of disability progression and is scored from 0 to 10 based on the neurologic exam and ambulation

Epidemiology

- onset 17-35 yr; F:M = 3:1
- PPMS occurs in an older population with F=M

Diagnosis for RRMS

- demonstration of both dissemination in time and space based on the revised McDonald criteria (2010)
 - dissemination in time: 2 or more attacks, simultaneous presence of asymptomatic gadolinium enhancing and non-enhancing MRI lesions at any time, or a new T2 and/or gadolinium-enhancing lesion(s) on follow-up MRI
 - dissemination in space: ≥ 1 T2 lesions on MRI in at least 2 of the 4 CNS regions (periventricular, juxtacortical, infratentorial, or spinal cord) or developing a second attack that implicates a different CNS region

Clinical Features

- symptoms include numbness, visual disturbance (optic neuritis), weakness, spasticity, diplopia (e.g. INO), impaired gait, vertigo, bladder dysfunction
- Lhermitte's sign:** flexion of neck causes electric shock sensation down back into limbs indicating cervical cord lesion
- Uhthoff's phenomenon:** worsening of symptoms (classically optic neuritis) in heat
- SPMS: classically weakness of legs in pyramidal distribution paired with cerebellar findings of arms (i.e. intention tremor)
- symptoms not commonly found in MS: visual field defects, aphasia, apraxia, progressive hemiparesis
- relapse: acute/subacute onset of clinical dysfunction that peaks from days to weeks, followed by remission with variable symptom resolution (symptoms must last at least 24 h)
- in RRMS, average 0.4 to 0.6 relapses/yr, but higher disease activity in 1st yr of disease

Investigations

- MRI:** demyelinating plaques appear as hyperintense lesions on T2 weighted MRI, with active lesions showing enhancement with gadolinium
 - typical locations: periventricular, corpus callosum, cerebellar peduncles, brainstem, juxtacortical region, and dorsolateral spinal cord
 - Dawson's fingers: periventricular lesions extending into corpus callosum
 - cranial MRI is more sensitive than spinal MRI
- CSF:** oligoclonal bands in 90%, increased IgG concentration
- evoked potentials (visual/auditory/somatosensory):** delayed but well-preserved wave forms

Treatment

- acute treatment:** methylprednisolone 1,000 mg IV daily x 3-7 d (no taper required); if poor response to corticosteroids may consider plasma exchange
- disease modifying therapy (DMT)**
 - goals: decrease relapse rate, decrease progression of disability, slow accumulation of MRI lesions
 - first line: teriflunomide, interferon- β (injection: Betaseron[®], Avonex[®], Rebi[®]), glatiramer acetate (injection: Copaxone[®]), BG-12 (Tecfidera[®])
 - second line: natalizumab (Tysabri[®]) (monthly IV infusion), fingolimod (Gilenya[®])
 - increased risk of progressive multifocal leukoencephalopathy (PML)
 - CIS: early treatment with interferons may delay potential second attack
 - RRMS: DMT reduces rate of relapse by about 30%
 - PPMS/SPMS: no proven efficacy of DMTs
- symptomatic treatment**
 - spasticity: baclofen, tizanidine, dantrolene, benzodiazepine, botulinum toxin
 - bladder dysfunction: oxybutynin
 - pain: TCA, carbamazepine, gabapentin
 - fatigue: amantadine, modafinil, methylphenidate
 - depression: antidepressant, lithium
 - constipation: high fibre intake, stool softener, laxatives
 - sexual dysfunction: sildenafil (Viagra[®]), tadalafil (Cialis[®]), vardenafil (Levitra[®], Staxyn[®])
- education and counselling:** MS Society, support groups, psychosocial issues

Prognosis

- good prognostic indicators: female, young, RRMS, presenting with optic neuritis, low burden of disease on initial MRI, low rate of relapse early in disease
- PPMS: poor prognosis, higher rates of disability, poor response to therapy

Fingolimod for Relapsing-Remitting Multiple Sclerosis

Cochrane DB Syst Rev 2016;4:CD009371

Purpose: Systematic literature review of the evidence for fingolimod in treatment of relapsing-remitting multiple sclerosis.

Study: Meta-analysis of six randomized controlled trials (n=5,152 patients) of the benefits and harms of fingolimod and other disease modifying drugs in treatment of relapsing-remitting multiple sclerosis.

Results: Compared to placebo and interferon beta-1a, fingolimod increases the probability of being relapse free at 24 months (RR 1.44 vs. placebo, RR 1.18 vs. interferon beta-1a) but has little to no effect on disability progression (RR 1.07 vs. placebo, RR 1.02 vs. interferon beta-1a). Fingolimod use was associated with a higher incidence of adverse events and discontinuation within 6 months.

Conclusions: Fingolimod significantly reduces disease activity in relapse-remitting multiple sclerosis compared to placebo but does not prevent disability. Its use is associated with adverse events and requires close patient monitoring, particularly within the first 6 months. Further study is needed to assess the benefits of fingolimod versus other disease modify drugs.

Recombinant Interferon Beta or Glatiramer Acetate for Delaying Conversion of the First Demyelinating Event to Multiple Sclerosis

Cochrane DB Syst Rev 2008;2:CD005278

Study: Meta-analysis of RCTs of clinically isolated syndrome (CIS) patients treated with immunomodulatory drugs.

Primary Outcomes: Proportion of patients converting to clinically definite MS and adverse effects.

Results: Three trials (n=1,160) tested the efficacy of interferon (IFN- α) and no trial tested glatiramer acetate (GA). A pooled odds ratio (OR) of 0.53 (95% CI 0.40-0.71, p<0.0001) for patients on IFN vs. placebo at 1 yr. Two year follow-up odds ratio was 0.52 (95% CI 0.38-0.70, p<0.0001). There was no significant increase in adverse events for those on IFN- α .

Conclusions: IFN- α treatment can delay progression to clinically definite MS in patients with CIS over 2 yr.

Risk of Natalizumab-Associated Progressive Multifocal Leukoencephalopathy

NEJM 2012;366:1870-80

Purpose: To assess the risk of progressive multifocal leukoencephalopathy (PML) in multiple sclerosis patients treated with natalizumab.

Study: A retrospective analysis funded of clinical studies, a Swedish patient registry and post-marketing sources, funded by Biogen Idec and Elan Pharmaceuticals.

Population: 99, 571 patients with relapsing-remitting multiple sclerosis treated with natalizumab.

Results: 212 of 99, 571 natalizumab-treated patients developed PML (2.1 cases per 1000 patients). Of the 54 PML patients with pre-diagnosis samples, all were positive for anti-JC antibodies. The highest risk of PML was in patients positive for anti-JC antibodies, treated with immunosuppressants prior to natalizumab, and had received 25-48 months of natalizumab (11.1 cases per 1000 patients). Patients negative for anti-JC antibodies were at lowest risk of PML (0.09 cases per 1000 patients).

Conclusions: In multiple sclerosis patients treated with natalizumab, those with positive anti-JC antibodies, lengthy treatment with natalizumab, and prior use of immunosuppressants, together or independently, were at highest risk of developing PML.

Common Medications

Table 25. Common Medications – Major Issues

Indications	Mechanism of Action/Class	Generic Name	Trade Name	Dosing	Contraindications	Side Effects
Parkinson's Disease	Dopamine precursor	levodopa + carbidopa	Sinemet®	Carbidopa 25 mg/levodopa 100 mg PO tid Maximum 200 mg carbidopa and 2,000 mg levodopa per day	Narrow-angle glaucoma, use of MAO inhibitor in last 14 d, history of melanoma or undiagnosed skin lesions	Nausea, hypotension, hallucinations, dyskinesias in last 14 d, history of melanoma or undiagnosed skin lesions
	Dopamine agonist	bromocriptine	Parlodel®	1.25 mg PO bid, increase by 2.5 mg/d q2-4wk, up to 10-30 mg PO tid	Concomitant use of potent inhibitors of CYP3A4, uncontrolled HTN, ischemic heart disease, peripheral vascular disease; caution with renal or hepatic disease	Hypotension, N/V, dizziness, constipation, diarrhea, abdominal cramps, H/A, nasal congestion, drowsiness, hallucinations
	MAO B inhibitor	selegiline	Eldepryl®	5 mg PO bid	Concomitant use of meperidine or tricyclic antidepressants	H/A, insomnia, dizziness, nausea, dry mouth, hallucinations, confusion, orthostatic hypotension, increased akinesia, risk of hypertensive crisis with tyramine-containing foods
Myasthenia Gravis	Acetylcholinesterase inhibitor	pyridostigmine	Mestinon®	600 mg/d PO divided in 5-6 doses Range 60-1,500 mg/d	GI or GU obstruction	Nausea, vomiting, diarrhea, abdominal cramps, increased peristalsis, increased salivation, increased bronchial secretions, miosis, diaphoresis, muscle cramps, fasciculations, muscle weakness
Acute Migraine	Triptan (selective 5-hydroxytryptamine receptor agonist)	sumatriptan	Imitrex®	25-100 mg PO prn, maximum 200 mg/d	Hemiplegic/basilar migraine, ischemic heart disease, CVD, uncontrolled HTN, use of ergotamine/5-HT ₁ agonist in past 24 h, use of MAO inhibitor in last 14 d, severe hepatic disease	Vertigo, chest pain, flushing, sensation of heat, hypertensive crisis, peripheral vascular disease, coronary artery vasospasm, cardiac arrest, nausea, vomiting, H/A, hyposalivation, fatigue
	Ergot (5-HT _{1D} receptor agonist)	dihydroergotamine	Migranal®	Nasal spray 0.5 mg/spray, maximum 4 sprays/d	Hemiplegic/basilar migraine, high-dose ASA therapy, uncontrolled HTN, ischemic heart disease, peripheral vascular disease, severe hepatic or renal dysfunction, use of triptans in last 24 h, use of MAO inhibitors in last 14 d	Coronary artery vasospasm, transient myocardial ischemia, myocardial infarction, ventricular tachycardia, ventricular fibrillation; may cause significant rebound H/A
Migraine Prophylaxis	Anticonvulsant	topiramate	Topamax®	25 mg OD PO (in evening); may increase weekly by 25 mg/d to a max 50 mg bid		Sedation, mood disturbance, cognitive dysfunction, anorexia, nausea, diarrhea, paresthesias, metabolic acidosis, glaucoma, SJS/TEN
	β-blocker	propranolol	Inderal®	80 mg/d divided every 6-8 h; increase by 20-40 mg/dose every 3-4 wk to max 160-240 mg/d in divided doses q6-8h	Uncompensated CHF, severe bradycardia or heart block, severe COPD or asthma	Fatigue, cognitive dysfunction, disturbed sleep, rashes, dyspepsia, dry eyes, heart failure, bronchospasm, risk of acute tachycardia and HTN if withdrawal
Epilepsy	Anticonvulsant for partial ± 2° generalization, generalized tonic-clonic	carbamazepine	Tegretol®	Start at 100-200 mg PO OD-tid, increase by 200 mg/d up to 800-1,200 mg/d	History of bone marrow depression, hepatic disease, hypersensitivity to the drug, use of MAO inhibitor in last 14 d	Drowsiness, H/A, unsteadiness, dizziness, N/V, skin rash, agranulocytosis/aplastic anemia (rare)
	Anticonvulsant for partial, tonic-clonic, status epilepticus	phenytoin	Dilantin®	100 mg PO tid, maintenance dose up to 200 mg PO tid SE: 10-15 mg/kg IV loading dose then maintenance doses of 100 mg PO or IV q6-8h	Hypersensitivity, pregnancy, breastfeeding; caution with P-450 interactions	Hypotension, SJS/TEN, SLE-type symptoms, gingival hypertrophy, peripheral neuropathy, H/A, blood dyscrasias, nystagmus, N/V, constipation, sedation, teratogenic
	Anticonvulsant for partial or generalized, absence seizures	valproic acid	Depakene® Apo-Valproic®	10-15 mg/kg/d PO in divided doses, increase incrementally until therapeutic dose to max of 60 mg/kg/d	Hypersensitivity, hepatic disease, urea cycle disorders	Hepatic failure, H/A, somnolence, alopecia, N/V, diarrhea, tremor, diplopia, thrombocytopenia, hypothermia, pancreatitis, encephalopathy
	Anticonvulsant for absence seizures	ethosuximide	Zarontin®	500 mg/d PO, increase by 250 mg every 4-7 d to max 1.5 g/d in divided doses	Hypersensitivity (succinimides)	CNS depression, blood dyscrasias, SLE, SJS, GI symptoms
Stroke Prevention in AF	Anticoagulant (direct thrombin inhibitor)	dabigatran	Pradaxa®	110 mg PO bid or 150 mg PO bid	CrCl <30 mL/min, significant hemostatic impairment or CNS lesions within 6 mo with high risk of bleeding	Dyspepsia, gastritis, bleeding
	Anticoagulant (Factor Xa inhibitor)	rivaroxaban	Xarelto®	15 mg PO daily or 20 mg PO daily	Concomitant anticoagulant, hepatic disease, pregnancy, strong CYP3A4 and P-gp inhibitors e.g. itraconazole, ritonavir	Bleeding
	Anticoagulant (Factor Xa inhibitor)	apixaban	Eliquis®	2.5 mg PO bid or 5 mg PO bid	Active bleeding, gastrointestinal bleeding, recent cerebral infarction, active peptic ulcer disease with recent bleeding, hepatic disease with coagulopathy	Bleeding (conjunctival, gastrointestinal, gingival, contusion, hematoma, epistaxis, hematuria)

Table 25. Common Medications – Major Issues (continued)

Indications	Mechanism of Action/Class	Generic Name	Trade Name	Dosing	Contraindications	Side Effects
Mild to Moderate AD or DLB	Cholinesterase Inhibitor	donepezil	Aricept®	5 mg PO OD, may increase to 10 mg PO OD after 4-6 wk	Hypersensitivity to donepezil or to piperidine derivatives	Diarrhea, N/V, insomnia, muscle cramps, fatigue, anorexia, HTN, syncope, AV block
Multiple Sclerosis	MS Disease Modifying Therapy	interferon-β-1b	Betaseron®	0.25 mg (8 MU) SC every other day	Pregnancy, hypersensitivity to natural or recombinant interferon-β	Injection site reactions, injection site necrosis, flu-like symptoms (fever, chills, myalgia; tend to decrease over time)
		interferon-β-1a SC	Rebif®	44 µg SC 3 times/wk		
	MS Disease Modifying Therapy	glatiramer acetate	Copaxone®	30 µg IM once weekly	Hypersensitivity to glatiramer or mannitol	Injection site reactions, nausea, transient chest pain, vasodilation
		natalizumab	Tysabri®	20 mg SC OD		
MS Disease Modifying Therapy					Hypersensitivity to natalizumab, progressive multifocal leukoencephalopathy (PML)	Rash, nausea, arthralgia, H/A, infections, rare risk of PML and melanoma
MS Disease Modifying Therapy					Not available	Diarrhea, transaminitis, H/A, bradyarrhythmia, lymphopenia
Spasticity (i.e. MS)	Muscle Relaxant – Antispastic	baclofen	Lioresal®	5 mg PO tid, increase by 15 mg/d q3d to max dose 80 mg/d in three divided doses	Hypersensitivity to baclofen	Transient drowsiness, daytime sedation, dizziness, weakness, fatigue, convulsions, constipation, nausea

Landmark Neurology Trials

Trial	Reference	Results
NASCET	<i>NEJM</i> 1991;7:445-53	Patients with symptomatic carotid stenosis of 70-99% benefited more from carotid endarterectomy than best medical therapy
Interferon-β Multiple Sclerosis Study Group Trial	<i>Neurology</i> 1993;43:655-61	Interferon-β-1b reduces relapse rate and severity of relapses in RRMS
NINDS rtPA	<i>NEJM</i> 1995;333:1581-7	rtPA reduces mortality and long-term disability when administered within 3 h of acute stroke
SPARCL	<i>NEJM</i> 2006;355:549-59	The observed benefit of statins in cardiovascular disease is also extended to patients with a recent stroke or TIA
ECASS 3	<i>NEJM</i> 2008;359:1317-29	rtPA improved clinical outcomes when administered within 3 to 4.5 h of acute ischemic stroke
PROFESS	<i>NEJM</i> 2008;359:1238-51	ASA + dipyridamole and clopidogrel showed similar benefits in secondary stroke prevention
RELY	<i>NEJM</i> 2009;361:1139	Dabigatran superior to warfarin for stroke prevention in patients with atrial fibrillation
ROCKET-AF	<i>NEJM</i> 2011;365:883-891	Rivaroxaban noninferior to warfarin stroke prevention in patients with atrial fibrillation
ERS	<i>NEJM</i> 2011;365:981-992	Apixaban superior to warfarin for stroke prevention in patients with atrial fibrillation
CREST	<i>NEJM</i> 2010;363:11-23	Carotid stenting and endarterectomy had similar benefits in reduction of stroke, MI, and death in carotid stenosis, but in the periprocedural period, stenting had a higher rate of stroke, while endarterectomy had a higher rate of MI
INTERACT2	<i>NEJM</i> 2013;368:2355-65	Intensive lowering of blood pressure (SBP < 140) in spontaneous intracerebral hemorrhage did not improve mortality or severe disability but improved functional outcomes (odds ratio for greater disability, 0.87; 95% CI, 0.77 to 1.00; P=0.04)
MR CLEAN	<i>NEJM</i> 2015;372:11-20	Intra-arterial treatment (intra-arterial thrombolysis, mechanical treatment, or both) for emergency revascularization administered within 6 h after stroke onset was effective and safe for acute ischemic stroke caused by proximal intracranial occlusion of the anterior circulation

Differential Diagnoses of Common Neurosurgical Presentations

Intracranial Mass Lesions	Disorders of the Spine	Peripheral Nerve Lesions
<p>Disorders of the Spine Peripheral Nerve Lesions</p> <p>Tumour Metastasis Astrocytoma Meningioma Vestibular schwannoma (acoustic neuroma) Pituitary adenoma Primary CNS lymphoma</p> <p>Pus/Inflammation Cerebral abscess, extradural abscess, subdural empyema Encephalitis (see Infectious Diseases, ID19) Tumefactive MS</p> <p>Blood Extradural (epidural) hematoma Subdural hematoma Ischemic stroke Hemorrhage: SAH, ICH, IVH</p> <p>Cyst Arachnoid cyst Dermoid cyst Epidermoid cyst Colloid cyst (3rd ventricle)</p>	<p>Extradural Degenerative: disc herniation, canal stenosis, spondylolisthesis/spondylolysis Infection/inflammation: osteomyelitis, discitis Ligamentous: ossification of posterior longitudinal ligament (OPLL) Trauma: mechanical compression/instability, hematoma Tumours (55% of all spinal tumours): lymphoma, metastases (lymphoma, lung, breast, prostate), neurofibroma</p> <p>Intradural Extradural Vascular: dural arteriovenous fistula, subdural hematoma (especially if on anticoagulants) Tumours (40% of all spinal tumours): meningioma, schwannoma, neurofibroma</p> <p>Intradural Intramedullary Tumours (5% of all spinal tumours): astrocytomas, ependymomas, hemangioblastomas and dermoids Syringomyelia: trauma, congenital, idiopathic Infectious/inflammatory: TB, sarcoid, transverse myelitis Vascular: AVM, ischemia</p>	<p>Neuropathies Traumatic Entrapments Iatrogenic Inflammatory Tumours</p>

INTRACRANIAL PATHOLOGY

Intracranial Pressure Dynamics

Table 1. Approach to Intracranial Pathology

Issue	Time Frame	Features
Vascular	Sudden	No H/A = occlusive H/A = hemorrhagic
Metabolic	Hours to days	Affects entire CNS
Infectious	Days to weeks	Often a source of infection or immunodeficiency on history
Tumour	Months	<p>Increased ICP: Initially → H/A Constant Progressive Severe Worse in morning and/or wakes from sleep</p> <p>As ICP increases: Blurry vision Projectile vomiting (may initially present without nausea)</p> <p>Severely raised ICP: Cushing's reflex 1. Bradycardia 2. HTN 3. Respiratory irregularity</p>

Table 2. Consequences of Common Brain Lesions

Location of Lesion	Consequence
Frontal Lobe Usually large lesions produce symptoms	Abulia, disinhibition, apathy, executive dysfunction, deficits in orientation and judgment, \pm primitive reflex re-emergence, \pm contralateral upper motor neuron signs (upgoing Babinski reflex and pronator drift)
Frontal Eye Fields	Gaze deviation toward side of a destructive lesion Gaze deviation away from irritative lesion (i.e. seizure)
Broca's Area Posterior inferior frontal gyrus of dominant hemisphere	Non-fluent, dysarthric, aphasia Repetition impaired Comprehension spared
Occipital Lobe	Contralateral homonymous hemianopsia
Parietal Lobe Either side Dominant side (Left) Non-dominant side (Right)	Dressing apraxia, cortical sensory loss, lower homonymous quadrantanopia. Inattention or extinction of non-dominant side Aphasias, Gerstmann's syndrome Hemispatial neglect, apraxias, agnosias (if temporal involvement)
Temporal Lobe	Hippocampus: anterograde amnesia Upper homonymous hemianopia Wernicke's aphasia (if left/dominant side)
Wernicke's Area Posterior superior temporal gyrus of dominant hemisphere	Fluent aphasia Repetition impaired Comprehension impaired
Basal Ganglia	Resting tremor Chorea Athetosis Hemiplegia if internal capsule involved
Subthalamic Nucleus	Contralateral hemiballismus
Brainstem	Absent brainstem reflexes: oculocephalic, oculovestibular, corneal, gag, and cough Dorsal midbrain/Pineal Gland: Parinaud's syndrome (supranuclear upward gaze palsy) Pons: locked-in syndrome Below red nucleus: decerebrate posture Above red nucleus: decorticate posture Reticular activating system (midbrain): reduced level of arousal Cerebellar pontine angle: disequilibrium, ataxia and other CN V,VII,VIII deficits
Cerebellar Hemisphere	Intention tremor Ipsilateral limb ataxia Fall towards side of lesion
Cerebellar Vermis	Truncal ataxia Dysarthria

ICP/Volume Relationship

- Monro-Kellie Doctrine: the brain is encased in a rigid skull with constant intracranial volume consisting of CSF, blood and brain
- the increase in one constituent will: 1) necessitate the redistribution of CSF, blood and/or brain and 2) increase ICP
- compensatory mechanisms initially maintain a normal ICP
- Compensatory reserve (spatial compensation): 60-80mL in young people, 100-140mL in elderly (largely due to cerebral atrophy)
 - **immediate:** egression of CSF through foramen magnum to spinal canal, displacement of venous blood from sinuses into jugular veins
- once compensation is exhausted, ICP rises exponentially:
 - **late:** displacement of arterial blood (decreased CPP) eventually leading to ischemia, increasing brain edema or expanding mass displaces parenchyma into compartments under less pressure (Table 3)
 - **end:** cessation of cerebral perfusion when $ICP > MAP$, cerebral herniation down into foramen magnum

**Figure 5. ICP volume curve**

Adapted from: Lindsay KW, et al. Neurology and neurosurgery illustrated. © 2004. With permission from Elsevier

Cerebral Blood Flow

- brain receives about 15% of cardiac output (~750 mL/min)
- CBF is the vital parameter for brain function and depends on cerebral perfusion pressure (CPP) and cerebral vascular resistance (CVR)
- CPP is dependent on the difference between mean arterial pressure (MAP) and Intracranial Pressure (ICP) (Normal CPP >50 mmHg)
- cerebral autoregulation: mechanism that maintains constant CBF despite changes in CPP, unless:
 - high ICP such that CPP <40 mmHg
 - MAP >150 mmHg or MAP <50 mmHg
 - increased CO₂ = increased CBF via vasodilation
 - O₂ <50 mmHg = increased CBF via vasodilation
 - brain injury: e.g. SAH, severe trauma

ICP Measurement

- normal ICP 10-15 mmHg for adult, 3-7 mmHg for child, 1.5-6 mmHg for infant; varies with patient position
 - moderate elevation >20 mmHg
 - severe elevation >40 mmHg

Acute Monitoring

- indications include: severe TBI (GCS <8T) + abnormal CT; normal CT under some conditions
- methods: "gold standard" is intraventricular catheter, (external ventricular drain (EVD)), is the most accurate method and allows therapeutic drainage of CSF. Non-invasive methods (including transcranial Doppler, CT/MRI, funduscopy etc) fail to measure ICP accurately enough to be used as routine measurement techniques

Chronic Monitoring

- fiberoptic monitor (intraventricular, intraparenchymal, subdural), subarachnoid bolt (Richmond screw), and epidural monitor

Elevated ICP

Etiology

- **increased intracranial pressure**
 - intracranial mass (tumour, cyst)
 - cerebral edema
 - ♦ vasogenic: BBB compromised (meningitis, hypertensive encephalopathy, tumour, late ischemia)
 - ♦ cytotoxic: BBB intact (cell death in: early ischemia, brain injury, encephalitis, status epilepticus)
 - ♦ interstitial: transudation of CSF into peri-ventricular white matter in hydrocephalus
 - ♦ osmotic: osmotic gradient increases intracellular free H₂O (acute hyponatremia, hepatic encephalopathy)
 - other space occupying lesions: depressed skull fracture, foreign body, pus/empyema
- **increased intracranial blood volume**
 - space occupying blood: epidural and subdural hematomas, intraparenchymal and subarachnoid hemorrhages
 - venous obstruction (venous sinus thrombosis, superior vena cava syndrome, cor pulmonale, venous sinus compression)
 - impaired autoregulation (hypotension, HTN, brain injury, status epilepticus)
 - vasodilatation (increased pCO₂/decreased pO₂/decreased extracellular pH)
- increased intracranial CSF volume
- increased production (rare): choroid plexus papilloma
- hydrocephalus: obstructive vs. non-obstructive (see Table 6)
- idiopathic intracranial HTN (pseudotumour cerebri) – see *Idiopathic Intracranial Hypertension, NS8*

CBF = CPP / CVR
CPP = MAP - ICP

MAP Targets in Trauma

TBI: MAP >80 mmHg
SCI: MAP between 85-90 mmHg in first 7d post injury

Autoregulation: CBF maintained despite change in CPP

Figure 6. Cerebral autoregulation curve

Adapted from: Lindsay KW, et al. Neurology and neurosurgery illustrated. © 2004. With permission from Elsevier

Lumbar puncture can be used for ICP monitoring, though it is not the most accurate. LP can precipitate tonsillar and uncal herniation with elevated ICP and is absolutely contraindicated with known/suspected intracranial mass

Consider Monitoring ICP in the Following Situations

- Patients with an abnormal head CT (SAH, hematoma, contusion, basal cistern compression, swelling, and herniation) and GCS score ≤ 8 after CPR

Or

- Patients with a normal head CT and GCS score of ≤8 AND the presence of two or more of the following:
 - >40 yr
 - Unilateral or bilateral motor posturing
 - sBP <90 mmHg
 - Post-operative monitoring
 - Investigation of NPH

Cautioned medication use in elevated ICP

- Nitroprusside – can raise ICP in patients with intracranial mass lesions due to direct vasodilation (arterial > venous)
- Nitroglycerine – can raise ICP via vasodilation but less so than Nitroprusside because venous > arterial
- Succinylcholine – induced fasciculations may increase ICP

Clinical Features

Table 3. Clinical Features of Elevated ICP

Clinical Features	Acutely Elevated ICP	Chronic Progressive ICP Elevation
Headache	Both aggravated by stooping, coughing, straining Morning headaches: vasodilatation due to increased CO ₂ with recumbency	
Nausea and Vomiting	Present in both, though greater predilection in acutely elevated ICP	
Level of Consciousness	Lethargy if ICP = dBP or midbrain compression	Irritability, inattentiveness. Normal or modestly reduced LOC, confusion
GCS	Significant decline in GCS Best index to monitor progress and predict outcome of acute intracranial process (see <i>Neurotrauma, NS30</i>)	Can be unchanged or modestly decreased
Optic Disc Changes	Subtle changes suggesting papilledema (subtle elevations in disc margin, mild disc hyperemia) ± retinal hemorrhages (may take 24-48 h to develop)	Obvious papilledema
Visual Changes	Less common. Often not affected initially, however visual obscurations, flickering or blurring can occur	Optic atrophy/blindness due to chronic papilledema Enlarged blind spot, if advanced → episodic constrictions of visual fields (“grey-outs” lasting ~20 min) Differentiate from papillitis (usually unilateral with decreased visual acuity)
Extra-Ocular Movements	Less common. CN VI palsy: due to long intracranial course, more sensitive to ICP changes and thus earlier sign of acutely increased ICP Often falsely localizing (causative lesion remote to nerve) Upward gaze palsy and sunset eyes (especially in children with obstructive hydrocephalus)	Often full EOM
Herniation Syndromes	Often occur (see Table 4)	Present if acute on chronic presentation
Neurologic Deficits	Focal deficits present	Focal deficits can be present

Blood Brain Barrier

Glucose and amino acids cross slowly
Non-polar/lipids cross fast

Infarction/neoplasm → destroy tight junctions
→ vasogenic edema

Cushing's Triad of Acute Raised ICP

(full triad seen in 1/3 of cases)

- Hypertension
- Bradycardia (late finding)
- Irregular respiratory pattern

Papilledema

- Optic disc swelling with blurred margins (most commonly bilateral)
- Larger blind spot

Investigations

- patients with suspected elevated ICP require an urgent CT/MRI to identify etiology, assess for midline shift/herniation
- ICP monitoring where appropriate

Figure 7. Herniation types

Herniation Syndromes

Table 4. Herniation Syndromes

Herniation Syndrome	Definition	Etiology	Clinical Features
1. Subfalcine	Cingulate gyrus herniates under falx	Lateral supratentorial lesion	Usually asymptomatic Warns of impending transtentorial herniation Risk of ACA compression
2. Central Tentorial (Axial)	Displacement of diencephalon through tentorial notch	Supratentorial midline lesion Diffuse cerebral swelling Late uncal herniation	Small pupils, moderately dilated, fixed (rostral to caudal deterioration), sequential failure of diencephalon, medulla Decreased LOC (midbrain compression), EOM/upward gaze impairment (“sunset eyes”): compression of pretectum and superior colliculi (Parinaud’s syndrome) Risk of PCA compression Brainstem (Duret) hemorrhage: secondary to shearing of basilar artery perforating vessels Diabetes insipidus (traction on pituitary stalk and hypothalamus), end-stage sign
3. Lateral Tentoria (Uncal)	Uncus of temporal lobe herniates down through tentorial notch	Lateral supratentorial lesion (often rapidly expanding traumatic hematoma)	Ipsilateral non-reactive dilated pupil (earliest, most reliable sign) + ipsilateral EOM paralysis, ptosis (CN III compression) Decreased LOC (midbrain compression) Risk of PCA compression Contralateral hemiplegia ± extensor (upgoing) plantar response ± ipsilateral hemiplegia (“Kernohan’s notch” – a false localizing sign resulting from pressure from the edge of the tentorium on the contralateral cerebral peduncle)
4. Upward	Cerebellar vermis herniates through tentorial incisura	Posterior fossa mass, brainstem or cerebellar infarction, exacerbated by ventriculostomy or VP shunt	Cerebellar infarct (superior cerebellar artery [SCA] compression) Hydrocephalus (cerebral/sylvian aqueduct compression)
5. Tonsillar	Cerebellar tonsils herniate through foramen magnum	Infratentorial lesion Following central tentorial herniation Following LP in presence of intracranial mass lesion	Neck stiffness and head tilt (tonsillar impaction) Decreased LOC (midbrain compression) Flaccid paralysis Respiratory irregularities, respiratory arrest (compression of medullary respiratory centres) Blood pressure instability (compression of medullary cardiovascular centres)

Treatment of Elevated ICP

- treatment principle: treat primary etiology (i.e. remove mass lesions, ensure adequate ventilation for example in ARDS)
- if elevated ICP persists following treatment of primary cause, consider therapy when ICP >20 mmHg
- targets: ICP <20 mmHg, CPP >65 mmHg, MAP >90 mmHg

Table 5. Management of Elevated ICP

Consideration	Intervention	Rationale
Conservative Measures		
Position	Elevate head of bed at 30° Maintain neck in neutral position	Increases 1. Jugular venous patency 2. intracranial venous outflow with minimal effect on MAP
Fever Management	Acetaminophen or mechanical cooling	Decrease metabolic demands to decrease CBF and minimize brain injury
Prevent Hypotension	PRN: fluid, vasopressors, dopamine, norepinephrine	Maintains CBF
Normocarbida	Ventilate to pCO ₂ 35-40 mmHg	Prevents vasodilatation
Adequate O₂	Target pO ₂ >60 mmHg	Prevents hypoxic brain injury
Osmolar Diuresis	Mannitol 20% IV solution 1-1.5 g/kg, then 0.25 g/kg q6h to serum osmolality of 315-320 Acts in 15-30 min, maintain sBP >90 mmHg	Increase serum tonicity → osmotically drives fluid out of brain
Corticosteroids	Dexamethasone	Decrease vasogenic edema over subsequent days around brain tumour, abscess, blood No proven value in head injury or stroke
Aggressive Measures		
Sedation	Usually Propofol Others: barbituates/codeine, or fentanyl/MgSO ₄ Light = barbituates/codeine Heavy = fentanyl/MgSO ₄	Reduces sympathetic tone Reduces HTN induced by muscle contraction
Paralysis	Vecuronium	Reduces sympathetic tone Reduces HTN induced by muscle contraction
Barbiturate-Induced Coma (refractory ICP)	Phentobarbital 10 mg/kg over 30 min, then 1 mg/kg q1h continuous infusion	Reduce CBF and metabolism Decreases mortality, but no affect on neurologic outcome No role for the use of hypothermia in head injury
Hyperventilate	Target pCO ₂ 30-35 mmHg	Decreases CBF and thus ICP but use for brief periods only
Drain CSF	Insert EVD (if acute) or shunt Drain 3-5 mL CSF	Reduces intracranial volume
Decompression	Decompressive craniectomy	Allows brain to swell while reducing risk of herniation

Treatment of Elevated ICP

ICP HEAD

Intubate
Calm (sedate)/Coma
Place drain/Paralysis
Hyperventilate
Elevate head
Adequate BP
Diuretic (mannitol)

Idiopathic Intracranial Hypertension (Pseudotumour Cerebri)

Definition

- raised ICP with papilledema, but without: mass, hydrocephalus, infection, or hypertensive encephalopathy (diagnosis of exclusion)

Etiology

- unknown (majority), but associated with:
 - dural sinus thrombosis
 - **habitus/diet:** obesity, hypervitaminosis A
 - **endocrine:** reproductive age, menstrual irregularities, Addison's/Cushing's disease
 - **hematologic:** iron deficiency anemia, polycythemia vera
 - **drugs:** steroid withdrawal, tetracycline, amiodarone, lithium, nalidixic acid, oral contraceptive
- risk factors overlap with those of venous sinus thrombosis; similar to those for gallstones ("fat, female, fertile, forties")

Epidemiology

- incidence: general population ~1-2/100,000 per year; obese women of childbearing age 19-21/100,000

Clinical Features

- **symptoms:** H/A in >90%, nausea, impaired vision, pulsatile intracranial noise, diplopia can occur with CN VI palsy
- **signs:** CN VI palsy can occur (otherwise no neurologic deficits), visual acuity and field deficits, papilledema, optic atrophy

- **morbidity:** risk of blindness, which is not reliably correlated to duration, symptoms or clinical course
- **clinical course:** usually self-limited, recurrence in 10%, chronic in some

Investigations

- **MRI-brain** (with and without contrast): slit like ventricles and distended perioptic subarachnoid space, but otherwise normal
 - rule out: venous sinus thrombosis, mass, infection, hydrocephalus
- **LP findings**
 - opening pressure >20 mm H₂O
 - normal CSF analysis
- **ophthalmologic:** fields, acuity, papilledema

Treatment

- **lifestyle change:** encourage weight loss, fluid/salt restriction
- **pharmacotherapy:** acetazolamide (decreases CSF production), thiazide diuretic, or furosemide; discontinue offending medications
- **surgery:** if above fail, serial LPs, shunts, optic nerve sheath decompression (if progressive impairment of visual acuity)
- **long term:** 2 yr follow-up, repeat imaging to rule out occult tumour, ophthalmology follow-up

Hydrocephalus

- for hydrocephalus in children, see *Pediatric Neurosurgery, NS36*

Definition

- accumulation of excess CSF in the brain, functionally divided into obstructive and communicating
 - flow of CSF: produced by choroid plexus, lateral ventricles → foramen of Monroe → 3rd ventricle → cerebral/sylvian aqueduct → 4th ventricle → foramina of Luschka (lateral) and Magendie (medial) → subarachnoid space where CSF is re-absorbed by arachnoid villi/granulations into dural venous sinuses

CSF production = CSF reabsorption = ~ 500 mL/d in normal adults
 Normal CSF volume ~150 mL (50% spinal, 50% intracranial) → 25 mL intraventricular, 50 mL subarachnoid)

Classification

Table 6. Classification of Hydrocephalus

Disorder	Definition	Etiology	Findings on CT/MRI
Obstructive (Non-Communicating) Hydrocephalus	CSF Circulation blocked within ventricular system proximal to the arachnoid granulations	Acquired Aqueductal Stenosis: adhesions after infection, hemorrhage; gliosis, tumour (e.g. medulloblastoma) Intraventricular lesions: tumours, e.g. 3rd ventricle colloid cyst, hematoma Mass causing tentorial herniation causing aqueduct/4th ventricle compression Others: neurosarcoidosis, abscess/granulomas, arachnoid cysts Congenital Primary aqueductal stenosis, Dandy-Walker malformation, Arnold-Chiari malformation, myelomeningocele, encephalocele (see <i>Pediatric Neurosurgery, NS36</i>)	Ventricular enlargement proximal to block (enlarged temporal horns, ballooning frontal and/or occipital horns, enlarged 3rd ± 4th ventricles) Periventricular hypodensity/lucency (transependymal migration of CSF forced into extracellular space) Sulcal effacement, reduced visibility of sylvian and interhemispheric fissures
Non-Obstructive (Communicating) Hydrocephalus	Most commonly CSF absorption blocked at extraventricular site = arachnoid granulations, rarely CSF absorption is overwhelmed by increased production	Post-infectious (#1 cause) → meningitis, abscess, cysticercosis Post-hemorrhagic (#2 cause) → SAH, IVH, traumatic Leptomeningeal carcinomatosis – metastatic meningitis Choroid plexus papilloma Idiopathic → normal pressure hydrocephalus	All ventricles dilated
Normal Pressure Hydrocephalus (NPH)	Persistent ventricular dilatation in the context of normal CSF pressure	Idiopathic (50%) Others: subarachnoid hemorrhage, meningitis, trauma, radiation-induced	Enlarged ventricles without increased prominence of cerebral sulci
Hydrocephalus Ex Vacuo	Ventricular enlargement resulting from atrophy of surrounding brain tissue	Normal aging Degenerative dementias see <i>Neurology, N23</i> (Alzheimer's, Frontal Temporal, Creutzfeldt-Jacob Disease)	Enlarged ventricles and sulci Cerebral atrophy

Figure 8. The flow of CFS

Etiology

- impaired CSF dynamics
 - obstruction of CSF flow
 - decreased CSF absorption
 - increased CSF production (rarely in choroid plexus papilloma – 0.4-1% of intracranial tumours)
- congenital and acquired causes

Epidemiology

- estimated prevalence 1-1.5%; incidence of congenital hydrocephalus ~1-2/1,000 live births

Clinical Features

- acute hydrocephalus: signs and symptoms of acutely elevated ICP (see Table 3)
- chronic/gradual onset hydrocephalus: (weeks to months) (i.e. NPH) presents with a classic triad (Hakim's Triad)
 - Ataxia (magnetic gait) + apraxia (pressure of ventricle on lower extremity motor fibres → gait disturbance)
 - Incontinence (pressure on cortical bowel/bladder centre)
 - Dementia (pressure on frontal lobes)

Investigations

- imaging
 - CT/MRI findings (see Table 6)
 - ultrasound (through anterior fontanelle in infants): ventriculomegaly, size and location of lesions (e.g. IVH)
 - mantleradionuclide cisternography can test CSF flow and absorption rate (unreliable)
- ICP monitoring (e.g. LP, EVD) may be used to investigate NPH and test response to shunting (lumbar tap test)

Treatment

- external ventricular drain (EVD)
- intermittent LPs for transient **communicating** hydrocephalus (SAH, IVH in premature infants)
- surgical**: surgical removal of obstruction (if possible) or excision of choroid plexus papilloma
- eliminating obstruction (i.e. excision of mass, posterior fossa decompression for Chiari Malformation)
- endoscopic
 - endoscopic third ventriculostomy (ETV) ± choroid plexus cauterization (for obstructive hydrocephalus)
 - endoscopic placement of aqueductal stent
- shunt
 - ventriculoperitoneal (VP): most common shunt
 - ventriculopleural (VPL)
 - ventriculoatrial (VA)
 - lumboperitoneal: for communicating hydrocephalus and pseudotumour cerebri

Shunt Complications

Table 7. Shunt Complications

Complication	Etiology	Clinical Features	Investigations
Obstruction (most common) Proximal Catheter Valve Distal Catheter	Obstruction by choroid plexus Buildup of proteinaceous accretions, blood, cells (inflammatory or tumour) Infection Disconnection or damage	Acute hydrocephalus signs and symptoms of Increased ICP	"Shunt series" (plain x-rays of entire shunt that only rule-out disconnection, break, tip migration) CT Radionuclide "shuntogram"
Infection (3-6%)	<i>S. epidermidis</i> <i>S. aureus</i> <i>P. acnes</i> Gram-negative bacilli	Fever, N/V, anorexia, irritability Meningitis Peritonitis Signs and symptoms of shunt obstruction Shunt nephritis (VA shunt)	CBC Blood culture Tap shunt for CandS (LP usually NOT recommended)
Overshunting (10% over 6.5 yr)	Slit ventricle syndrome, collapse of ventricles leading to occlusion of shunt ports by ependymal lining Chronic or recurring headaches often relieved when lying down CT/MRI Slit-like ventricles on imaging Subdural hematoma Collapsing brain tears bridging veins (especially common in NPH patients) Secondary craniostylosis (children): apposition and overlapping of the cranial sutures in an infant following decompression of hydrocephalus	Asymptomatic Headaches, vomiting, somnolence Abnormal head shape	CT Clinical CT
Seizures (5.5% risk in 1st yr, 1.1% after 3rd yr)	Ventricular shunts only		EEG
Inguinal Hernia (17% incidence with VP shunt inserted in infancy) ± skin breakdown over hardware	Increased intraperitoneal pressure/fluid results in hernia becoming apparent	Inguinal swelling, discomfort	U/S

Classic (Hakim's) Triad of NPH Progression
"Wet, wacky, wobbly": Incontinence, Dementia, Ataxia

Important Features to Note on CT and MRI
(± contrast enhancement)

- Lesions (± edema, necrosis, hemorrhage)
- Midline shifts and herniations
- Effacement of ventricles and sulci (often ipsilateral), basal cisterns
- Single or multiple (multiple implies metastasis)

Complications of Specific Hydrocephalus Treatments

- VP Shunt – intra-abdominal cysts, adhesions, ascites
- VA Shunt – greater infection risk, septicemia, emboli
- VPI Shunt – pleural effusion, hydrothorax, respiratory distress
- LP Shunt – radiculopathy, CSF leaks, adhesions, arachnoiditis
- ETV – 56% success rate, hypothalamic injury, traumatic basilar aneurysm

CNS Tumours

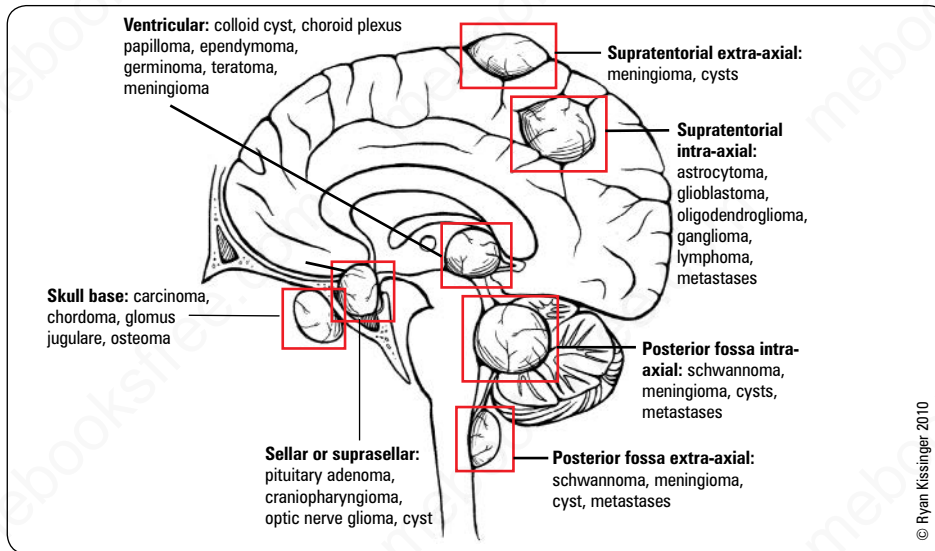

Figure 9. Tumours of the CNS

Classification

- primary vs. metastatic (e.g. primary in breast, lung), intra-axial (parenchymal) vs. extra-axial, supratentorial vs. infratentorial, adult vs. pediatric
- benign: non-invasive, but can be devastating due to mass effect in fixed volume of skull (e.g. most meningiomas, WHO Grade I)
- malignant: implies rapid growth, invasiveness, possibly drop-metastases to spinal cord from a primary CNS tumour (rare)
- classification of nervous system tumours (* = most common). In 2007, the WHO Classification of CNS tumours was based solely on histology; an update was made in 2016 which bases the classification on a combination of histology (phenotype) and molecular genetics (genotype) for “integrated” diagnoses:
 - **neuroepithelial**
 - ♦ astrocytic tumours
 - oligoastrocytic tumours: oligoastrocytoma
 - neuronal and mixed neuronal-glioma tumours: ganglion cell tumours, cerebral neurocytomas
 - embryonal tumours: medulloblastoma, primitive neuroectodermal tumours (PNET)
 - other: pineal, ependymal, and choroid plexus tumours
 - **meningeal:** meningiomas*, mesenchymal, hemangioblastomas
 - **cranial and paraspinous nerves:** schwannoma, neurofibroma
 - **lymphomas and hematopoietic:** primary CNS lymphoma, plasmacytoma
 - **germ cell:** germinomas, teratomas, choriocarcinomas
 - **sellar region:** craniopharyngiomas, spindle cell oncocytoma, pituitary adenomas*
 - **cysts:** epidermoid/dermoid cysts, colloid cysts
 - **local extension:** chordomas, glomus jugulare tumours
 - **metastatic tumours:** lung*, breast*

Familial Syndromes Associated with CNS Tumours

- see [Medical Genetics, MG7](#)

Investigations

- CT, MRI, stereotactic biopsy (tissue diagnosis and molecular markers for prognosis), metastatic workup, tumour markers (i.e. germ cell tumours)

Treatment

- **conservative:** serial Hx, Px, imaging for slow growing/benign lesions
- **medical:** corticosteroids to reduce ICP, cytotoxic cerebral edema, pharmacologic (i.e. pituitary adenoma)
- **surgical:** total or partial excision (decompressive, palliative), shunt if hydrocephalus
- **radiotherapy:** conventional fractionated radiotherapy (XRT), stereotactic radiosurgery (e.g. Gamma Knife®)
- **chemotherapy:** e.g. alkylating agents (i.e. temozolomide (GBM)*, vincristine, cyclophosphamide, etc.)

DDx for Ring Enhancing Lesion on CT with Contrast

MAGICAL DR

Metastases*
Abscess*
Glioblastoma (high grade astrocytoma)*
Infarct
Contusion
AIDS (toxoplasmosis)
Lymphoma
Demyelination
Resolving hematoma, Radiation Necrosis
(*3 most common diagnoses)

Ring Enhancing Lesions in Patients with HIV

DDx: Toxoplasmosis or CNS Lymphoma
Tx: Pyrimethamine and Sulfadiazine; later brain biopsy if no resolution with antimicrobial
Primary CNS lymphoma reported in 6-20% of HIV infected patients

Primary Brain Tumours

Rarely undergo metastasis
Adults = mostly supratentorial
Children = mostly infratentorial

New onset communicating hydrocephalus in a patient with cancer should raise the suspicion of leptomeningeal carcinomatosis

Table 8. Tumour Location: Etiology and Clinical Presentation

	Supratentorial	Infratentorial (Posterior Fossa)
Epidemiology		
Age <15 yr Incidence: 2-5/100,000/yr 60% infratentorial	Astrocytoma (all grades) (50%) Craniopharyngioma (2-5%) Others: pineal region tumours, choroid plexus tumours, ganglioglioma, DNET	Medulloblastoma (15-20%) Cerebellar astrocytoma (15%) Ependymoma (9%) Brainstem astrocytoma
Age >15 yr 80% supratentorial	High grade astrocytoma (12-15%, e.g. GBM) Metastasis (15-30%, includes infratentorial) Meningioma (15-20%) Low grade astrocytoma (8%) Pituitary adenoma (5-8%) Oligodendroglioma (5%) Other: colloid cyst, CNS lymphoma, dermoid/epidermoid cysts	Metastasis Acoustic neuroma (schwannoma) (5-10%) Hemangioblastoma (2%) Meningioma
Clinical Presentation		
Shared Features (from elevated ICP)	Headache: usually worse in AM and made worse with straining, coughing Nausea/Vomiting Papilledema Diplopia - CN VI palsy	
Distinguishing Features	Seizure: commonly the first symptom Progressive neurological deficits (70%) Frontal lobe: hemiparesis, dysphasia, personality changes, cognitive changes Temporal lobe: auditory/olfactory hallucinations, memory deficits, contralateral superior quadrantanopsia Mental Status Change: depression, apathy, confusion, lethargy "Tumour TIA" – stroke like symptoms caused by a) occlusion of vessel by tumour cells b) hemorrhage c) 2° to "steal phenomenon" - blood is shunted from ischemic regions to non-ischemic regions Endocrine disturbance - with pituitary tumours (see Endocrinology, E19)	Brainstem involvement: cranial nerve deficits and long tract signs Nausea/Vomiting: compression on vagal nucleus/area postrema Diplopia: direct compression CN VI Vertigo Nystagmus Truncal Ataxia + Titubation: cerebellar vermis lesions Limb Ataxia, dysmetria, intention tremor: cerebellar hemisphere lesions Obstructive hydrocephalus more common than supratentorial lesions

Metastatic Tumours

Brain Metastasis

- most common intra-cranial tumour in adults (~50% of all brain tumours)
- afflict ~25% of patients with any cancer
- hematogenous spread most common
- 80% are hemispheric, often at grey-white matter junction or temporal-parietal-occipital lobe junction
 - likely emboli spreading to terminal MCA branches

Investigations

- identify primary tumour
 - full metastatic workup (CXR, CT chest/abdo, abdominal U/S, nuclear medicine scan/PET, mammogram)
- CT with contrast → round, well-circumscribed, often ring enhancing, ++ edema, often multiple
- MRI more sensitive, especially for posterior fossa
- consider biopsy in unusual cases or if no primary tumour identified

Treatment

- medical
 - phenytoin (or levetiracetam) for seizure prophylaxis if patient presents with seizure
 - dexamethasone to reduce edema given with ranitidine
 - chemotherapy (e.g. small cell lung cancer), but difficult delivery across BBB
- radiation
 - stereotactic radiosurgery (highly focused fraction of radiation targeted to tumour): for discrete, deep-seated/inoperable tumours
 - multiple lesions: use WBRT; consider stereotactic radiosurgery if <3 lesions
 - post-operative adjuvant RT consideration
- surgical
 - single/solitary lesions: use surgery and radiation

Prognosis

- median survival without treatment once symptomatic is ~1 mo, with optimal treatment 6-9 mo. The disease-specific Graded Prognostic Assessment (Ds-GPA) is a useful prognostic index. Prognosis varies depending on primary tumour type and extent of systemic tumour burden

Figure 10. Multiple brain metastases
(see arrows)

Most Common Cancers that Metastasize to the CNS

Site of Primary	Frequency of CNS metastasize
Lung	44%
Breast	10%
Kidney (RCC)*	7%
GI	6%
Melanoma	3%

*RCC=renal cell carcinoma

Astrocytoma

- most common primary intra-axial brain tumour, common in 4th-6th decades

Table 9. World Health Organization Astrocytoma Grading System

	Typical CT/MRI Findings	Survival
I – Pilocytic astrocytoma	± mass effect, ± enhancement	>10 yr, cure if gross total resection
II – Low grade/diffuse*	Mass effect, no enhancement	5 yr
III – Anaplastic*	Complex enhancement	1.5-2 yr
IV – Glioblastoma multiforme (GBM)	Necrosis (ring enhancement)	12 mo, 10% at 2 yr

*IDH mutant WHO Gr II/III tumours have a better overall prognosis than IDH wild-type; following IDH stratification, the chromosomal 1p/19q codeletion has prognostic value in IDH mutated grade II-III gliomas after adjustment for tumour proliferation, age, and adjuvant treatment

Clinical Features

- sites: cerebral hemispheres >> cerebellum, brainstem, spinal cord
- symptoms: recent onset of new/worsening H/A, N/V, seizure, ± focal deficits or symptoms of increased ICP

Investigations

- CT/MRI with contrast: variable appearance depending on grade
 - hypodense on CT, hypointense on T1 MRI, hyperintense on T2 MRI
 - low grade: most do not enhance and have calcification on CT
 - high grade: most enhance with CT contrast dye/gadolinium, possibly with central necrosis (especially if IDH wildtype)

Treatment

- low grade diffuse astrocytoma**
 - close follow-up, radiation, chemotherapy, and surgery all valid options
 - de-differentiation to more malignant grade; typically occurs faster when diagnosed after age 45
 - surgery: not curative, trend towards better outcomes
 - radiotherapy alone or post-operative prolongs survival (retrospective evidence)
 - chemotherapy: usually reserved for tumour progression
- high grade astrocytomas (anaplastic astrocytoma and GBM)**
 - goal is to prolong “quality” survival
 - surgery**
 - gross total resection: maximal safe resection + fractionated radiation with 2 cm margin + concomitant and adjuvant temozolomide
 - except: nearing end-of-life; or extensive brainstem, bilateral, or dominant lobe GBM involvement
 - awake craniotomy for tumours in ‘eloquent’ regions (e.g. speech and language regions or near motor strip)
 - stereotactic biopsy if resection not possible, followed by fractionated radiation with 2 cm margin
 - expectant** (based on functional impairment – Karnofsky score <70; patient’s/family’s wishes)
 - chemotherapy**: ~20% response rate, temozolomide (agent of choice); better response to temozolomide predicted by MGMT gene hypermethylation
- multiple gliomas**: WBRT ± chemotherapy

Meningioma

- most common *primary* intracranial tumour, arising from arachnoid membrane
- often calcified, may cause hyperostosis of adjacent bone (detectable on imaging)
- classically see Psammoma bodies (“meningocytic whorls”) on histology
- location: 70% occur along the parasagittal convexity, falx cerebri, and sphenoid bone; other locations: tuberculum sellae, foramen magnum, olfactory groove, and CP angle

Clinical Features

- middle aged, slight female predominance (M:F = 1:1.8), high progesterone receptors (increase in size with pregnancy)
- many are asymptomatic and can be an incidental finding; when symptoms occur focal neurologic deficits specific to location, ± seizures, symptoms of increased ICP
- molecular changes: between 40-80% of meningiomas contain mutations in chromosome 22 (involved in suppressing tumour growth); some have extra copies of PDGFR and EGFR; some are associated with NF2, if presence of neurofibromatosis type 2

Figure 11. High grade astrocytoma on CT

Comparison of a Strategy Favouring Early Surgical Resection vs. a Strategy Favouring Watchful Waiting in Low-Grade Gliomas

JAMA 2012; 308(18): 1881-8

Purpose: To examine “watchful waiting” vs. early surgical resection of low grade gliomas.

Study: A population-based parallel cohort study was undertaken between two hospitals that each favoured different management approaches for low grade gliomas (biopsy and watchful waiting vs. early surgical resection).
Results: 66 patients were included from the watchful waiting hospital and 87 patients from the early resection centre. Median follow-up was 7.0 and 7.1 years at each centre. The two groups were equivalent in terms of baseline parameters. Overall, survival was significantly better with early surgical resection (watchful waiting: median survival of 5.9 years 95% CI, 4.5-7.3 vs. early resection: median survival was not reached due to prolonged length of life, $p < 0.01$).

Conclusions: Early surgical resection of low grade-gliomas is associated with better overall survival as compared to watchful waiting.

Bevacizumab Plus Radiotherapy-Temozolamide for Newly Diagnosed Glioblastoma

NEJM 2014;370:709-722

Purpose: To evaluate the effect of combined bevacizumab and radiotherapy-temozolamide in the treatment of newly diagnosed glioblastoma.

Study: Patients with supratentorial glioblastoma randomly assigned to receive intravenous bevacizumab or placebo plus radiotherapy and oral temozolamide for 30 wk total in cycles, followed by bevacizumab or placebo monotherapy. Outcomes were progression-free survival and overall survival.
Results: 458 patients in bevacizumab group, 463 patients in placebo. The median progression-free survival was longer in the bevacizumab group compared with placebo (10.6 mo vs. 6.2 mo, HR 0.64, 95% CI 0.55-0.74), although overall survival did not differ significantly between groups (HR 0.88, 95% CI 0.76-1.02). Baseline health-related QOL and performance status were maintained longer in the bevacizumab group although there was a higher frequency of adverse events.

Conclusions: The addition of bevacizumab to radiotherapy-temozolamide improves progression-free survival but not overall survival in patients with glioblastoma.

Figure 12. Meningioma on CT

Investigations

- **CT with contrast:** homogeneous, densely enhancing, along dural border (“dural tail”), well circumscribed, usually solitary (10% multiple, likely with loss of NF2 gene/22q12 deletion)
- **MRI with contrast:** characterization of mass and provides a better assessment of the patency of dural venous sinuses
- **angiography**
 - most are supplied by external carotid feeders (meningeal vessels)
 - can assess venous sinus involvement, “tumour blush” commonly seen (prolonged contrast image)

Treatment

- **conservative management:** asymptomatic and/or non-progressive on CT/MRI – serial monitoring for interval growth changes
- **surgery:** curative if complete resection and indicated when symptomatic and/or documented growth on serial CT/MRI
- **endovascular:** embolization for highly vascularized, likely bloody, tumours to facilitate surgery
- **radiation:** SRS may be an option for lesions <3 cm partially occluding the superior sagittal sinus; SRS or XRT for non-resectable, recurrent atypical/malignant meningiomas

Prognosis

- >90% 5 yr survival, recurrence rate variable (often ~10-20%)
- depends on extent of resection
- Simpson's classification: degree of surgical resection completeness with symptomatic recurrence

Vestibular Schwannoma (Acoustic Neuroma)

- slow-growing (average of 1-10 mm/yr), benign posterior fossa tumour (8-10% of tumours)
- arises from vestibular nerve of CN VIII in internal auditory canal, expanding into bony canal and cerebello-pontine angle (CPA)
- if bilateral, diagnostic of neurofibromatosis type II
- epidemiology: 1.5/100,000; all age groups affected, peaks at 4th-6th decades

Clinical Features

- **early clinical triad:** (tumour <2 cm) unilateral progressive hearing loss 98%, tinnitus, and disequilibrium (compression of CN VIII)
- **later clinical features**
 - tumour usually >2 cm: otalgia, facial numbness + weakness, changes to taste (due to CN V and VII compression, respectively)
 - tumour usually >4 cm: ataxia, H/A, N/V, diplopia, cerebellar signs (due to brainstem compression; ± obstructive hydrocephalus)

Investigations

- MRI with gadolinium or T2 FIESTA sequence (>98% sensitive/specific); CT with contrast 2nd choice
- audiogram, brainstem auditory evoked potentials, caloric tests

Treatment

- expectant: serial imaging (CT/MRI q6mo) and audiometry if tumour is small, hearing is still preserved, high perioperative risk, or elderly patient
- radiation: stereotactic radiosurgery or fractionated radiotherapy
- surgery: if lesion >3 cm, brainstem compression, edema, hydrocephalus
- curable if complete resection (almost always possible)
- operative complications: CSF leak, meningitis, required shunt; CN V, VII, VIII dysfunction (proportional to tumour size; only significant CNVIII disability if bilateral)
- implications for testing of family members of NF2 mutation carrier

Pituitary Adenoma

- primarily from anterior pituitary, 3rd-4th decades, M=F, associated with MEN-1 syndrome
- incidence in autopsy studies approximately 20%
- **classification**
 - microadenoma <1 cm; macroadenoma ≥1 cm
 - endocrine active (functional/secretory) vs. inactive (non-functional)
 - most common functional: prolactinomas, adrenocorticotrophic, growth-hormone producing
 - differential diagnosis: parasellar tumours (e.g. craniopharyngioma, tuberculum sellae meningioma), carotid aneurysm

Clinical Features

- **mass effects**
- H/A
- bitemporal hemianopsia (compression of optic chiasm); hydrocephalus (3rd ventricle compression)
- invasive adenomas: CN III, IV, V1, V2, VI palsy (cavernous sinus compression); ptosis and chemosis (cavernous sinus occlusion)

WHO Classification of Meningioma (by histology)

- Grade 1: low risk of recurrence
- Grade 2: intermediate risk of recurrence
- Grade 3: high risk of recurrence

Recommendations For Management Of Meningiomas

Lancet Oncol. 2016 Sep;17(9):e383-91.

European Association of Neuro-Oncology assessed available literature and rated scientific evidence and graded recommendation levels.

Despite high frequency of meningiomas, evidence for diagnosis and treatment recommendation are low. Prospective studies to generate new evidence is required.

Key recommendations include:

1. First standard therapy is gross total surgical resection (including involved dura).
2. Alternative treatments include radiosurgery for small tumours and fractionated radiotherapy in large/previously treated tumours.
3. New treatment concepts combining surgery and radiosurgery/fractionated radiotherapy to treat complete tumour volume are being developed.
4. Although pharmacological treatments are still experimental, antiangiogenic drugs, peptide receptor radionuclide therapy, and targeted agents are candidates for future pharmacological approaches to treat refractory meningioma of all WHO grades.

Progressive unilateral or asymmetrical sensorineural hearing loss = acoustic neuroma until proven otherwise

Figure 13. Vestibular schwannoma (tumour in cerebello-pontine angle)

Look For The Adenoma Please –

GH, LH, FSH, TSH, ACTH, Prolactin
A compressive adenoma in the pituitary will impair hormone production in this order (i.e. GH-secreting cells are most sensitive to compression)

- endocrine effects (see [Endocrinology, E15](#))
 - hyperprolactinemia (prolactinoma): infertility, amenorrhea, galactorrhea, decreased libido
 - ACTH production: Cushing's disease, hyperpigmentation
 - GH production: acromegaly/gigantism
 - panhypopituitarism: due to compression of pituitary (hypothyroidism, hypoadrenalism, hypogonadism)
 - diabetes insipidus (DI) – rare, except in apoplexy
- pituitary apoplexy (sudden expansion of mass due to hemorrhage or necrosis)
 - abrupt onset H/A, visual disturbances, ophthalmoplegia, reduced mental status, panhypopituitarism and DI
 - CSF rhinorrhea and seizures (rare)
 - signs and symptoms of subarachnoid hemorrhage (rare)

Investigations

- formal visual fields, CN testing
- endocrine tests (prolactin level, TSH, 8 AM cortisol, fasting glucose, FSH/LH, IGF-1), electrolytes, urine electrolytes, and osmolality
- imaging (MRI with and without contrast)

Treatment

- medical
 - for apoplexy: rapid corticosteroid administration ± surgical decompression
 - for prolactinoma: dopamine agonists (e.g. bromocriptine)
 - for Cushing's: serotonin antagonist (cyproheptadine), inhibition of cortisol production (ketoconazole)
 - for acromegaly: somatostatin analogue (octreotide) ± bromocriptine
 - endocrine replacement therapy
- surgical
 - endoscopic trans-sphenoidal, trans-ethmoidal, and less commonly trans-cranial approaches (i.e. for significant suprasellar extension)
- post-operative concerns: DI, adrenal insufficiency (AI), CSF leak
 - DI and AI: AM cortisol, serum sodium and osmolality, urine output and specific gravity (treatment - AI: glucocorticoids; DI: desmopressin/DDAVP)
 - CSF rhinorrhea: test for β transferrin

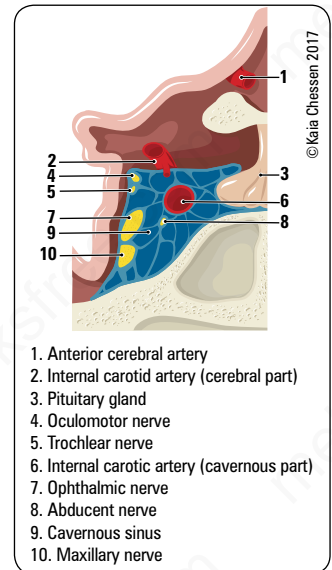

Figure 14. Cavernous Sinus

Cerebral Abscess

Definition

- pus in brain substance, surrounded by tissue reaction (capsule formation)

Etiology

- modes of spread: 10-60% of patients have no cause identified
- pathogens
 - *Streptococcus* (most common), often anaerobic or microaerophilic
 - *Staphylococcus* (penetrating injury)
 - Gram-negatives, anaerobes (*Bacteroides*, *Fusobacterium*)
 - in neonates: *Proteus* and *Citrobacter* (exclusively)
 - immunocompromised: fungi and protozoa (*Toxoplasma*, *Nocardia*, *Candida albicans*, *Listeria monocytogenes*, *Mycobacterium*, and *Aspergillus*)

Sources of Pus/Infection

- four routes of microbial access to CNS
 1. hematogenous spread: arterial and retrograde venous
 - ♦ adults: chest is #1 source (lung abscess, bronchiectasis, empyema)
 - ♦ children: congenital cyanotic heart disease with R to L shunt
 - ♦ immunosuppression (AIDS – toxoplasmosis)
 2. direct implantation (dural disruption)
 - ♦ trauma
 - ♦ iatrogenic (e.g. following LP, post-operative)
 - ♦ congenital defect (e.g. dermal sinus)
 3. contiguous spread (adjacent infection): from air sinus, naso/oropharynx, surgical site (e.g. otitis media, mastoiditis, sinusitis, osteomyelitis, dental abscess)
 4. spread from PNS (e.g. viruses: rabies, herpes zoster)
- common examples
 - epidural abscess: in cranial and spinal epidural space, associated with osteomyelitis
 - ♦ treatment: immediate drainage and antibiotics, surgical emergency if cord compression
 - subdural empyema: bacterial/fungal infection, due to contiguous spread from bone or air sinus, progresses rapidly
 - ♦ treatment: surgical drainage and antibiotics, 20% mortality
 - meningitis, encephalitis (see [Infectious Diseases, ID18](#))
 - cerebral abscess

Risk Factors

- lung abnormalities (infection, AV fistulas; especially Osler-Weber-Rendu syndrome [i.e. hereditary hemorrhagic telangiectasia])
- congenital coronary heart disease: R-to-L shunt bypasses pulmonary filtration of micro-organisms
- bacterial endocarditis
- penetrating head trauma
- immunosuppression (e.g. AIDS)
- dental abscess, poor dentition

Clinical Features

- focal neurological signs and symptoms
 - H/A, decreased LOC; hemiparesis and seizures in 50%
- mass effect, increased ICP and sequelae (cranial enlargement in children)
- hemiparesis and seizures in 50%
- ± signs and symptoms of systemic infection (low-grade fever, leukocytosis)

Complications

- with abscess rupture: ventriculitis, meningitis, venous sinus thrombosis
- CSF obstruction
- transtentorial herniation

Investigations

- CT scan often first test in emergency department
- MRI
 - imaging of choice
 - apparent diffusion coefficient (ADC) used to differentiate abscess (black) from tumour (white)
- WBC/ESR may be normal, blood cultures rarely helpful and LP contraindicated if large mass
- CSF: non-specific (high ICP, high WBC, high protein, normal carbohydrate), rarely helpful, usually negative culture

Treatment

- aspiration ± excision and send for Gram stain, acid fast bacillus (AFB), CandS, fungal culture
- excision preferable if location suitable
- antibiotics
 - empirically: vancomycin + ceftriaxone + metronidazole or chloramphenicol or rifampin (6-8 wk therapy)
 - revise antibiotics when C&S known
- anti-convulsants (1-2 yr)
- follow-up CT is critical (do weekly initially, more frequent if condition deteriorates)

Prognosis

- mortality with appropriate therapy ~10%, permanent deficits in ~50%

Figure 15. Cerebral abscess on CT

Recommendations For Duration Of Antibiotic Therapy For Brain Abscesses

Int J Infect Dis. 2010 Oct;14 Suppl 4:S79-92

Summary:

1. prudent period of 4-6 weeks of antibiotic therapy for surgically treated abscesses.
2. 6-8 weeks of IV treatment for abscesses treated medically only.
3. 6-8 weeks of IV treatment for multiple abscesses when larger ones are treated surgically.

Methods: systematic literature search using MEDLINE database for studies during 1988-2008 to methodologically evaluate all studies pertaining to brain abscess.

Results: several recommendations were made by extracting evidence; for duration of antibiotic therapy, it was noted that IV antibiotic therapies were usually ≥4 weeks. No studies have evaluated the duration of antibiotic therapy on outcome. Without evidence to safely evaluate endovenous therapy time, authors agreed with British Society for Antimicrobial Chemotherapy recommendations (see summary).

Blood

Table 10. Comparison of Epidemiology and Etiology of Intracranial Bleeds

Types of Hematoma/Hemorrhage	Etiology	Epidemiology	Clinical Features	CT Features	Treatment	Prognosis
Epidural Hematoma	Skull fracture causing middle meningeal bleed	M>F (4:1), associated with trauma	Lucid interval before LOC	Hyperdense lenticular mass with sharp margins, usually limited by suture lines	Craniotomy	Good with prompt management (Note: respiratory arrest can occur from uncal herniation)
Acute SDH	Ruptured subarachnoid bridging vessels	Age >50, associated with trauma	No lucid interval, hemiparesis, pupillary changes	Hyperdense crescentic mass, crossing suture lines	Craniotomy if bleed >1 cm thick	Poor
Chronic SDH	Ruptured subarachnoid bridging vessels	Age >50, EtOH abusers, anticoagulated	Often asymptomatic, minor H/A, confusion, signs of in-creased ICP	Hypodense crescentic mass, crossing suture lines	Burr hole to drain; craniotomy if recurs	Good
SAH	Trauma, spontaneous (aneurysms, idiopathic, AVM)	Age 55-60, 20% cases under age 45	Sudden onset thunderclap H/A, signs of increased ICP	Hyperdense blood in cisterns/fissures (sensitivity decreases over time)	Conservative: NPO, IV NS, ECG, Foley, BP 120-150, vasospasm prophylaxis (nimodipine); open vs. endovascular surgery to repair if rebleed	Poor: 50% mortality 30% of survivors have moderate to severe disability
ICH	HTN, vascular abnormality, tumours, infections, coagulopathy	Age >55, male, drug use (cocaine, EtOH, amphetamine)	TIA-like symptoms, signs of increased ICP	Hyperdense intra-parenchymal collection	Medical: decrease BP, control ICP Surgical: craniotomy	Poor: 44% mortality due to cerebral herniation

CT Density and MRI Appearance of Blood

Time	CT	MRI T1	MRI T2
Acute (<72 h)	Hyper.	Grey	Black
Subacute (<3 wk)	Iso.	White	White
Chronic (>3 wk)	Hypo.	Black	Black

MRI-T1: "George Washington Bridge"

MRI-T2: "Oreo" cookie – Black/White/Black

Extradural ("Epidural") Hematoma

Etiology

- temporal-parietal skull fracture: 85% are due to ruptured middle meningeal artery; remainder of cases are due to bleeding from middle meningeal vein, dural sinus, or bone/diploic veins

Epidemiology

- young adult, M>F = 4:1; rare before age 2 or after age 60
- 1-4% of traumatic head injuries

Clinical Features

- classic sequence (seen in <30%): post-traumatic reduced LOC, a lucid interval of several hours, then obtundation, hemiparesis, ipsilateral pupillary dilatation, and coma
- signs and symptoms depend on severity but can include H/A, N/V, amnesia, altered LOC, aphasia, seizures, HTN, and respiratory distress
- deterioration can take hours to days

Investigations

- CT without contrast: "lenticular-shaped" usually limited by suture lines but not limited by dural attachments

Treatment

- admission, close neurological observation with serial CT indicated if all of the following are present
 - small volume clot, minimal midline shift (MLS <5 mm), GCS >8, no focal deficit
- otherwise, craniotomy to evacuate clot, follow-up CT
- patients with initial EDH >10mL on CT within 2 hours or EDH in temporoparietal region are more likely to develop epidural hematoma enlargement and require close CT follow-up at 5-6 hr post impact
- mannitol pre-operative if elevated ICP or signs of brain herniation

Prognosis

- good with prompt management, as the brain is often not damaged
- worse prognosis if bilateral Babinski or decerebration pre-operative
- death is usually due to respiratory arrest from uncal herniation (injury to the midbrain)

Subdural Hematoma

Table 11. Comparison of Epidemiology and Etiology of Acute and Chronic SDH

	Acute SDH	Chronic SDH
Time Course	1-2 d after bleeding onset	≥15 d after bleeding onset
Etiology	Rupture of vessels that bridge the subarachnoid space (e.g. cortical artery, large vein, venous sinus) or cerebral laceration	Many start out as acute SDH Blood within the subdural space evokes an inflammatory response: Fibroblast invasion of clot and formation of neomembranes within days → growth of neocapillaries → fibrinolysis and liquefaction of blood clot (forming a hygroma) Course is determined by the balance of rebleeding from neomembranes and resorption of fluid
Risk Factors	Trauma, acceleration-deceleration injury, anticoagulants, alcohol, cerebral atrophy, infant head trauma	Older, alcoholics, patients with CSF shunts, anticoagulants, coagulopathies
Clinical Features	No lucid period, signs and symptoms can include: altered LOC, pupillary irregularity, hemiparesis	Often due to minor injuries or no history of injury May present with minor H/A, confusion, language difficulties, TIA-like symptoms, symptoms of raised ICP ± seizures, progressive dementia, gait problem Obtundation disproportionate to focal deficit; "the great imitator" of dementia, tumours
Investigations	CT: Hyperdense concave "crescentic" mass, crossing suture lines	CT: hypodense (liquefied clot), crescentic mass
Treatment	Craniotomy if clinically symptomatic, if hematoma > 1 cm thick, or if MLS > 5 mm (optimal if surgery < 4 h from onset) Otherwise observe with serial imaging	Seizure prophylaxis only if post-traumatic seizure Reverse coagulopathies Burr hole drainage of liquefied clot indicated if symptomatic or thickness > 1 cm; craniotomy if recurs more than twice
Prognosis	Poor overall since the brain parenchyma is often injured (mortality range is 50-90%, due largely to underlying brain injury) Prognostic factors: initial GCS and neurological status, post operative ICP	Good overall as brain usually undamaged, but may require repeat drainage

Figure 16. Extradural hematoma on CT

Poor Prognostic Indicators for Epidural Hematoma

- Older age
- Low GCS on admission
- Pupillary abnormalities (especially non-reactive)
- Longer delay in obtaining surgery (if needed)
- Post-operative elevated ICP

Figure 17. Subdural hematoma on CT

Use Of Drains Vs. No Drains After Burr-Hole Evacuation For Treatment Of Chronic Subdural Hematoma

Cochrane Database Syst Rev. 2016 Aug 31;(8):CD011402
Summary:
 1. some evidence that post-operative drainage is effective in reducing the symptomatic recurrence of chronic subdural hematoma
 2. The effect of drainage on the occurrence of surgical complications, mortality, and poor functional outcomes is uncertain due to low quality evidence
 3. No strong evidence of increase in complications when drains are used
Methods: comprehensive search strategy databases extracting 9 RCTs (n=968) comparing external subdural drains with no drains after burr-hole evacuation for treatment of chronic subdural hematoma.
Results: Significant reduction in the risk of recurrence with subdural drains (RR 0.45, 95% CI 0.32-0.61), no strong evidence of increase in complications (RR 0.78, 95% CI 0.77-1.72), mortality (RR 0.78, 95% CI=0.45-1.33), poor functional outcome (RR 0.68, 95% CI 0.44-1.05).

Cerebrovascular Disease

Ischemic Cerebral Infarction (80%)

- embolic, thrombosis of intracerebral arteries, vasculitis, hypercoagulability, etc. (see [Neurology, N50](#))

Intracranial Hemorrhage (20%)

- SAH, spontaneous ICH, IVH

Figure 18. Aneurysms of the Circle of Willis

Hemicraniectomy in Older Patients with Extensive Middle-Cerebral-Artery Stroke

NEJM 2014;370:1091-1100

Purpose: To determine if early decompressive hemicraniectomy reduces mortality among patients >60 yr.

Study: 112 patients >60 yr (median age 70 yr) with malignant MCA infarction randomly assigned to conservative ICU treatment versus hemicraniectomy. Endpoint was survival without severe disability (modified Rankin scale score 0-4).

Results: The proportion of patients who survived without severe disability was 38% in the hemicraniectomy group and 18% in the control group (OR 2.91, 95% CI 1.06-7.49). Modified Rankin scale scores in hemicraniectomy versus control group in terms of percentages of patients: 0-2 (0%, 0%), 3 or moderate disability (7%, 3%), 4 or moderate severe disability (32%, 15%), 5 or severe disability (28%, 13%) and 6 or death (33%, 70%). Infections were more frequent in the hemicraniectomy group and herniation more frequent in the control group.

Conclusions: Hemicraniectomy increased survival without severe disability among patients >60 yr with a malignant MCA infarction.

Subarachnoid Hemorrhage

Definition

- bleeding into subarachnoid space (intracranial vessel between arachnoid and pia)

Etiology

- trauma (most common)
- spontaneous
 - ruptured aneurysms (75-80%)
 - idiopathic (14-22%)
 - AVMs (4-5%)
- coagulopathies (iatrogenic or primary), vasculitides, tumours, cerebral artery dissections (<5%)

Epidemiology

- ~10-28/100,000 population/yr
- peak age 55-60, 20% of cases occur under age 45

Risk Factors

- HTN
- pregnancy/parturition in patients with pre-existing AVMs, eclampsia
- oral contraceptive pill
- substance abuse (cigarette smoking, cocaine, alcohol)
- conditions associated with high incidence of aneurysms (see [Intracranial Aneurysms, NS20](#))

Clinical Features of Spontaneous SAH

- sudden onset (seconds) of severe "thunderclap" H/A usually following exertion and described as the "worst headache of my life" (up to 97% sensitive, 12-25% specific)
- N/V, photophobia
- meningismus (neck pain/stiffness, positive Kernig's and Brudzinski's sign)
- decreased LOC (due to either raised ICP, ischemia, seizure)
- focal deficits: cranial nerve palsies (CN III, IV), hemiparesis
- ocular hemorrhage in 20-40% (due to sudden raised ICP compressing central retinal vein)
- reactive HTN

Hunt and Hess Grade (clinical grading scale for SAH)

Grade	Description
1	No Sx or mild H/A and/or mild meningismus
2	Grade 1 + CN palsy
3	Confusion/lethargy, mild hemiparesis, or aphasia
4	GCS <15 but >8, moderate-severe hemiparesis, mild rigidity
5	Coma (GCS <9), decerebrate, moribund appearance

Mortality of Grade 1-2 20%, increased with grade

- sentinel bleeds
 - represents undiagnosed SAH
 - SAH-like symptoms lasting <1 d (“thunderclap H/A”)
 - may have blood on CT or LP
 - ~30-60% of patients with full blown SAH give history suggestive of sentinel bleed within past 3 wk
- differential diagnosis: sentinel bleed, dissection/thrombosis of aneurysm, venous sinus thrombosis, benign cerebral vasculitis, benign exertional H/A

Investigations

- non-contrast CT – for diagnosis of SAH
 - 98% sensitive within 12 h, 93% within 24 h; 100% specificity
 - may be negative if small bleed or presentation delayed several days
 - acute hydrocephalus, IVH, ICH, infarct or large aneurysm may be visible
- lumbar puncture (highly sensitive) – for diagnosis of SAH if CT negative but high suspicion:
 - elevated opening pressure (>18 cm H₂O)
 - bloody initially, xanthochromic supernatant with centrifugation (“yellow”) by ~12 h, lasts 2 wk
 - RBC count usually >100,000/mm³ without significant drop from first to last tube (in contrast to traumatic tap)
 - elevated protein due to blood breakdown products
- four vessel cerebral angiography (“gold standard” for aneurysms)
 - demonstrates source of SAH in 80-85% of cases
 - angiogram negative SAH: repeat angiogram in 7-14 d, if negative → “perimesencephalic SAH”
- MRA and CTA: sensitivity up to 95% for aneurysms, CTA>MRA for smaller aneurysms and delineating adjacent bony anatomy

World Federation of Neurological Surgeons Grading of SAH

WFNS Grade	GCS Score	Aphasia, Hemiparesis, or Hemiplegia
0*		
1	15	-
2	13-14	-
3	13-14	+
4	7-12	+ or -
5	3-6	+ or -

*Intact aneurysm

Nontraumatic Subarachnoid Hemorrhage in the Setting of Negative Cranial Computed Tomography Results: External Validation of a Clinical and Imaging Prediction Rule

Ann Emerg Med 2012;59:460-8.e1-7. doi:10.1016

Background: Two rules for SAH diagnosis exist. A clinical prediction rule states that patients with acute severe H/A but without the clinical variables age ≥40 yr, neck pain, loss of consciousness, or onset of H/A with exertion are at low risk for SAH. An imaging prediction rule bases diagnosis on non-contrast cranial CT for patients within 6 h of H/A onset.

Methods: Matched case-control study of 55 patients at 21 emergency departments between 2000 and 2011, and diagnoses were verified by lumbar puncture.

Results: The clinical prediction rule for diagnosis of SAH was 97.1% sensitive, 22.7% specific, and had a negative likelihood ratio of 0.13. Using the imaging prediction rule resulted in a false negative rate of 20%.

Conclusions: Performing the clinical and imaging rules together has the potential for maximizing sensitivity of prediction and reducing rates of lumbar puncture, but using imaging alone can result in missed cases.

Figure 19. Diagnosis of SAH

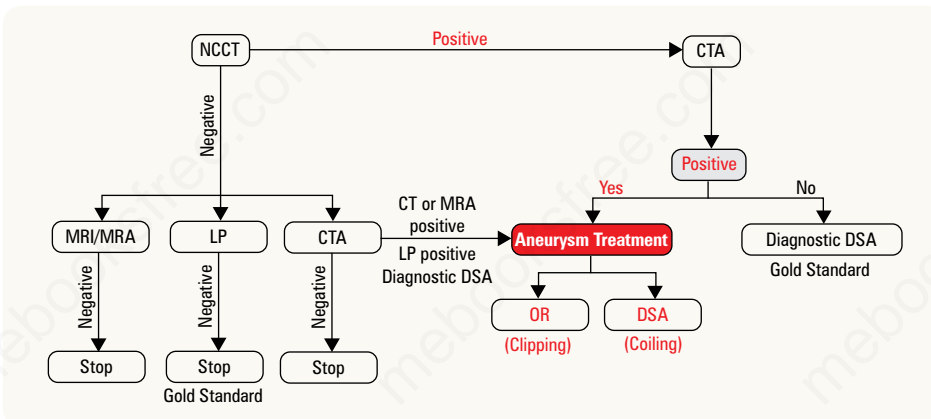

Figure 20. Approach to SAH

Adapted from: de Oliveira Manoel et al. (2014) Subarachnoid haemorrhage from a neuroimaging perspective. *Critical Care*

Treatment

- admit to ICU or NICU
 - oxygen/ventilation prn
 - NPO, bed rest, elevate head of bed 30°, minimal external stimulation, neurological vitals q1h
 - aim to maintain sBP = 120-150 (balance of vasospasm prophylaxis, risk of rebleed, risk of hypotension since CBF autoregulation impaired by SAH)
 - cardiac rhythm monitor, Foley prn, strict monitoring of ins and outs

The Vasograde: A Simple Grading Scale For Prediction Of Delayed Cerebral Ischemia After Subarachnoid Hemorrhage

Stroke. 2015; 46(7):1826-31

Background: Patients are classically at risk of delayed cerebral ischemia (DCI) after aneurysmal subarachnoid hemorrhage. We validated a grading scale—the VASOGRADE—for prediction of DCI.

Method: We used data of 3 phase II randomized clinical trials and a single hospital series to assess the relationship between the VASOGRADE and DCI.

Results: In a cohort of 746 patients, the VASOGRADE significantly predicted DCI (P<0.001). The VASOGRADE-Yellow had a tendency for increased risk for DCI (odds ratio [OR], 1.31; 95% CI, 0.77–2.23) when compared with VASOGRADE-Green; those with VASOGRADE-Red had a 3-fold higher risk of DCI (OR, 3.19; 95% CI, 2.07–4.50). VASOGRADE had an adequate discrimination for prediction of DCI (area under the receiver operating characteristics curve=0.63) and good calibration.

Conclusions: The VASOGRADE results validated previously published risk charts in a large and diverse sample of subarachnoid hemorrhage patients, which allows DCI risk stratification on presentation after subarachnoid hemorrhage. It could help to select patients at high risk of DCI, as well as standardize treatment protocols and research studies.

The VASOGRADE: A simple grading scale for prediction of delayed cerebral ischemia after subarachnoid hemorrhage

Stroke 2015;46: 1826-1831

- medications
 - IV NS with 20 mmol KCl/L at 125-150 cc/h
 - nimodipine 60 mg PO/NG q4h x 21 d for delayed cerebral ischemia neuroprotection; may discontinue earlier if patient is clinically well
 - seizure prophylaxis: levetiracetam (Keppra®) 500 mg PO/IV q12h x 1 wk
 - mild sedation prn
 - neuroprotection
 - the only validated neuroprotective agent is nimodipine
 - studies on the use of IV magnesium and endothelin-A antagonist (clazosentan) showed reduction in DCI and vasospasm, respectively, without any effect on functional outcome
 - a trial on the use of statins did not show any neuroprotective benefit

Complications

- vasospasm: vasoconstriction and permanent pathological vascular changes in response to vessel irritation by blood – can lead to delayed cerebral ischemia and death
 - onset: 4-14 d post-SAH, peak at 6-8 d; most commonly due to SAH, rarely due to ICH/IVH
 - clinical features (new onset ischemic deficit): confusion, decreased LOC, focal deficit (speech or motor e.g. pronator drift)
 - risk factors: large amount of blood on CT (high Fisher grade), smoking, increased age, HTN
 - “symptomatic” vasospasm in 20-30% of SAH patients
 - “radiographic” vasospasm in 30-70% of arteriograms performed 7 d following SAH
 - diagnosed clinically, and/or with transcranial Doppler (increased velocity of blood flow)
 - risk of cerebral infarct and death
 - treatment
 - ♦ hyperdynamic (“triple H”) therapy using fluids and pressors, usually after ruptured aneurysm has been clipped/coiled
 - ♦ direct vasodilation via angioplasty or intra-arterial verapamil for refractory cases
- delayed cerebral ischemia: neurological deterioration persisting more than 1 hour in the absence of any obvious contributing physiological, radiological or laboratory abnormalities
 - peaks 4-10 days post ictus
 - can progress to cerebral infarction and is associated with significant morbidity and mortality
 - mechanism behind DCI is unclear but includes vasospasm, vascular dysautoregulation, neurotoxic effects from the blood, inflammation, micro-thrombi and cortical spreading depolarizations
 - it is an essential target for SAH management
- hydrocephalus (15-20%): due to blood obstructing arachnoid granules
 - can be acute or chronic, requires extraventricular drain (EVD) or shunt, respectively
- neurogenic pulmonary edema
- hyponatremia: due to cerebral salt wasting (increased renal sodium loss and ECFV loss), not SIADH
- diabetes insipidus
- cardiac: arrhythmia (>50% have ECG changes), MI, CHF

Prognosis

- 10-15% mortality before reaching hospital, overall 50% mortality (majority within first 2-3 wk)
- 30% of survivors have moderate to severe disability
- a major cause of mortality is rebleeding, for untreated aneurysms:
 - risk of rebleed: 4% on first day, 15-20% within 2 wk, 50% by 6 mo
 - if no rebleed by 6 mo, risk decreases to same incidence as unruptured aneurysm (2%)
 - only prevention is early clipping or coiling of “cold” aneurysm
 - rebleed risk for “perimesencephalic SAH” is approximately same as for general population

VASOGRADE

VASOGRADE	WFNS	Modified Fischer scale
Green	1-2	1-2
Yellow	1-3	3-4
Red	4-5	Any

Long-Term Risk Of Recurrent Subarachnoid Hemorrhage, Death, Dependence And Standardized Mortality Ratios After Clipping Or Coiling Of An Intracranial Aneurysm (SAT)

Lancet. 2015 Feb 21; 385(9969): 691–697

Summary:

1. The probability of death or dependency was significantly greater in the neurosurgical group (vs. endovascular group) at 10 year FU.

2. Rebleeding was more likely in endovascular group (vs. neurosurgical group), but risk was small at 10 year FU.

3. Probability of disability free survival was significantly greater in the endovascular group (vs. neurosurgical group) at 10 year FU.

Methods:

RCT comparing endovascular coiling treatment with craniotomy and clipping for ruptured intracranial aneurysms in 2143 patients who were considered eligible for either modality or therapy between 1994-2002. 1644 patients were followed for deaths and outcomes for 10-18.5 years.

Results: At 10 years, 83% of endovascular coiling group and 79% of neurosurgical clipping group were alive. 82% of patients treated with endovascular coiling and 78% of patients treated with neurosurgical clipping were independent. Patients in the endovascular group were more likely to be alive and independent at 10 years vs. neurosurgery group (OR 1.34, 95% CI 1.07-1.67). Rebleeding risks from target aneurysm for endovascular group and neurosurgery group were 0.0216 (95% CI 0.0121-0.0383) and 0.0064 (95% CI 0.0024-0.0173), respectively.

Intracranial Aneurysms

Epidemiology

- prevalence 1-4% (20% have multiple)
- F>M; age 35-65 yr

Types

- saccular (berry)
 - most common type
 - located at branch points of major cerebral arteries (Circle of Willis)
 - 85-95% in carotid (anterior) system, 5-15% in vertebrobasilar (posterior) circulation
- fusiform
 - atherosclerotic
 - more common in vertebrobasilar system, rarely rupture
- infectious
 - secondary to any infection of vessel wall, 20% multiple
 - 60% *Streptococcus* and *Staphylococcus*
 - 3-15% of patients with bacterial endocarditis

Commonest Locations of Saccular Aneurysms

- AComm: 30%
- PComm: 25%
- MCA: 20%
- Basilar tip: 7%

Risk Factors

- autosomal dominant polycystic kidney disease (15%)
- fibromuscular dysplasia (7-21%)
- AVMs
- connective tissue diseases (Ehlers-Danlos, Marfan)
- family history
- bacterial endocarditis
- Osler-Weber-Rendu syndrome (hereditary hemorrhagic telangiectasia)
- atherosclerosis and HTN
- trauma

Table 12. Five Year Cumulative Rupture Risk in Unruptured Aneurysms Based on Size and Location

	Cavernous Carotid	AC/MC/IC	Vertebrobasilar/PC/PComm
<7 mm	0%	0%	2.5%
7-12 mm	0%	2.6%	14.5%
13-24 mm	3%	14.5%	18.4%
≥24 mm	6.4%	40%	50%

AC = anterior cerebral/anterior communicating artery; IC = internal carotid artery; MC = middle cerebral artery; PC = posterior cerebral artery; PComm = posterior communicating artery.
Lancet 2003;362:103-110

Clinical Presentation

- rupture (90%), most often SAH, but 30% ICH, 20% IVH, 3% subdural bleed
- sentinel hemorrhage ("thunderclap H/A") → requires urgent clipping/coiling to prevent catastrophic bleed
- mass effect (giant aneurysms)
 - internal carotid or anterior communicating aneurysm may compress:
 - ♦ the pituitary stalk or hypothalamus causing hypopituitarism
 - ♦ the optic nerve or chiasm producing a visual field defect
 - ♦ basilar artery aneurysm may compress midbrain, pons (limb weakness), or CN III
 - ♦ posterior communicating artery aneurysm may produce CN III palsy
 - ♦ intracavernous aneurysms (CN III, IV, V1, V2, VI)
- distal embolization (e.g. amaurosis fugax)
- seizures
- H/A (without hemorrhage)
- incidental CT or angiography finding (asymptomatic)

Investigations

- CT angiogram (CTA), magnetic resonance angiography (MRA), cerebral angiogram

Treatment

- **ruptured aneurysms**
 - overall trend towards better outcome with early surgery or coiling (48-96 h after SAH)
 - ♦ treatment options: surgical placement of clip across aneurysm neck, trapping (clipping of proximal and distal vessels), thrombosing using Guglielmi detachable coils (coiling) or flow diversion stents, wrapping (last resort)
 - choice of surgery vs. coiling not yet well defined: consider location, size, shape, and tortuosity of the aneurysm, patient comorbidities, age, and neurological condition; in general:
 - ♦ coiling: posterior > anterior circulation, deep/eloquent location, basilar artery bifurcation/apex, older age, presence of comorbidities, presence of vasospasm
 - ♦ clipping: superficial > deep, broad aneurysmal base, branching arteries at the aneurysm base, tortuosity/atherosclerosis of afferent vessels, dissection, hematoma, acute brainstem compression
- **unruptured aneurysms**
 - average 1% annual risk of rupture: risk dependent on size and location of aneurysm
 - no clear evidence on when to operate: need to weigh life expectancy
 - risk of morbidity/mortality of SAH (20%-50%) vs. surgical risk (2%-5%)
 - generally treat unruptured aneurysms >10 mm
 - consider treating when aneurysm 7-9 mm in middle-aged, younger patients or patients with a family history of aneurysms
 - follow smaller aneurysms with serial angiography

Risk Factors for Saccular (Berry) Aneurysms (SHAME)
Smoking
Hypertension
Adult Polycystic Kidney Disease
Marfan Syndrome
Ehlers-Danlos Syndrome

Long-Term, Serial Screening for Intracranial Aneurysms in Individuals with a Family History of Aneurysmal Subarachnoid Hemorrhage: A Cohort Study
Lancet Neurol 2014;13:385-392

Purpose: To examine the yield of long-term serial screening for intracranial aneurysms for individuals with a positive family history of aneurysmal subarachnoid hemorrhage (aSAH) (two or more first degree relatives who have had aSAH or unruptured intracranial aneurysms).

Study: Screening results from April 1 1993 to April 1 2013 were reviewed in a cohort study. MRA or CTA was done from age 16-18 to 65-70 yr. After a negative screen, individuals were advised to contact the clinic in 5 yr for follow-up.

Results: Aneurysms were identified in 11% of individuals at first screening (n=458), 8% at second screening (n=261), 5% at third screening (n=128), and 5% at fourth screening (n=63). Smoking (OR 2.7, 95% CI 1.2-5.9), history of previous aneurysms (3.9, 1.2-12.7), and familial history of aneurysms (3.5, 1.6-8.1) were significant risk factors for aneurysm at first screening. History of previous aneurysms was the only significant risk factor for aneurysms at follow-up screening (HR 4.5, 95% CI 1.1-18.7).

Conclusions: The benefit of long-term screening in individuals with a family history of aSAH is substantial up to and after 10 yr of follow-up and two initial negative screens.

The Unruptured Intracranial Aneurysm Treatment Score

Neurology, 2015;85(10):881-9

Objective: to develop an unruptured intracranial aneurysm (UIA) treatment score (UIATS) model that includes and quantifies key factors involved in clinical decision-making in the management of UIAs and to assess agreement for this model among specialists in UIA management and research.

Methods: An international multidisciplinary (neurosurgery, neuroradiology, neurology, clinical epidemiology) group of 69 specialists was convened to develop and validate the UIATS model using a Delphi consensus method.

Results: The UIATS accounts for 29 key factors in UIA management.

Conclusions: This novel UIA decision guidance study captures an excellent consensus among highly informed individuals on UIA management, irrespective of their underlying specialty.

Intracerebral Hemorrhage

Definition

- hemorrhage within brain parenchyma, accounts for ~10% of strokes
- can dissect into ventricular system (IVH) or through cortical surface (SAH)

Etiology

- HTN (usually causes bleeds at putamen, thalamus, pons, and cerebellum)
- hemorrhagic transformation (reperfusion post stroke, surgery, strenuous exercise, etc.)
- vascular anomalies
 - aneurysm, AVMs, and other vascular malformations (see *Vascular Malformations, NS23*)
 - venous sinus thrombosis
 - arteriopathies (cerebral amyloid angiopathy, lipohyalinosis, vasculitis)
- tumours (1%): often malignant (e.g. GBM, lymphoma, metastases)
- drugs (amphetamines, cocaine, alcohol, anticoagulants, etc.)
- coagulopathy (iatrogenic, leukemia, TTP, aplastic anemia)
- CNS infections (fungal, granulomas, herpes simplex encephalitis)
- post trauma (immediate or delayed, frontal and temporal lobes most commonly injured via coup-contre-coup mechanism)
- eclampsia
- post-operative (post-carotid endarterectomy cerebral reperfusion, craniotomy)
- idiopathic

Epidemiology

- 12-15 cases/100,000 population/yr

Risk Factors

- increasing age (mainly >55 yr)
- male gender
- HTN
- Black/Asian > Caucasian
- previous CVA of any type (23x risk)
- both acute and chronic heavy alcohol use; cocaine, amphetamines
- liver disease
- anticoagulants

Clinical Features

- TIA-like symptoms often precede ICH, can localize to site of impending hemorrhage
- gradual onset of symptoms over minutes-hours, usually during activity
- H/A, N/V, and decreased LOC are common
- specific symptoms/deficits depend on location of ICH

Investigations

- baseline severity score such as the ICH Score should be performed as part of the initial workup
- hyperdense blood on non-contrast CT
- CTA routine, if spot sign (contrast in the hematoma) demonstrated there is high likelihood of clot growth

Treatment

medical

- decrease MAP to pre-morbid level or by ~20% (target BP 140/90) in ED
- check PTT/INR, and correct coagulopathy
- control raised ICP (see *Intracranial Pressure Dynamics, NS4*)
- corticosteroids should NOT be used for elevated ICP in ICH
- levetiracetam/phenytoin for seizure prophylaxis
- follow electrolytes (SIADH common)
- angiogram to rule out vascular lesion unless >45 yr, known HTN, and putamen/thalamic/posterior fossa ICH (yield ~0%)

surgical

- craniotomy with evacuation of clot, treatment of source of ICH (i.e. AVM, tumour, cavernoma), ventriculostomy to treat hydrocephalus
- indications
 - symptoms of raised ICP or mass effect
 - rapid deterioration (especially if signs of brainstem compression)
 - favourable location (e.g. cerebellar, non-dominant hemisphere)
 - young patient (<50 yr)
 - if tumour, AVM, aneurysm, or cavernoma suspected (resection or clip to decrease risk of rebleed)
- contraindications
 - small bleed: minimal symptoms, GCS >10
 - poor prognosis: massive hemorrhage (especially dominant lobe), low GCS/coma, lost brainstem function
 - medical reasons (e.g. very elderly, severe coagulopathy, difficult location [e.g. basal ganglia, thalamus])

Location of ICH

- Basal Ganglia/Internal Capsule (50%)
- Thalamus (15%)
- Cerebral White Matter (15%)
- Cerebellum/Brainstem – usually pons (15%)
- Other (5%)

ICH Score Components

- GCS score
- ICH volume
- Presence of intraventricular hemorrhage
- Infratentorial origin
- Age

Early Surgery Versus Initial Conservative Treatment In Patients With Spontaneous Supratentorial Lobar Intracerebral Hematomas (STICH-II): A Randomized Trial

Lancet. 2013 Aug 3; 382(9890): 397-408

Summary: The STICH II (international, parallel-group trial comparing early surgical hematoma evacuation within 12 hour of randomization + medical treatment vs. initial medical treatment alone) results confirm that early surgery does not increase the rate of death or disability at 6 months and might have a small but clinically relevant survival advantage for patients with spontaneous superficial intracerebral haemorrhage without intraventricular haemorrhage.

Spetzler-Martin AVM Grading Scale

Item	Score
Size	
0-3 cm	1
3.1-6.0 cm	2
>6 cm	3
Location	
Noneloquent	0
Eloquent	1
Deep Venous Drainage	
Not present	0
Present	1

AVM grades calculated by adding the 3 individual Spetzler-Martin Scale scores from the above table. e.g. a 2 cm tumour in noneloquent location without deep venous drainage = Grade I

Prognosis

- 30-d mortality rate 44%, mostly due to cerebral herniation
- rebleed rate 2-6%, higher if HTN poorly controlled

Vascular Malformations

Types

- arteriovenous malformations (AVMs)
- cavernous malformations (= cavernomas, cavernous hemangiomas/angiomas)
- venous angioma
- capillary telangiectasias
- arteriovenous fistula (AVF) (carotid-cavernous fistula, dural AVF, vein of Galen aneurysm)
- “angiographically occult vascular malformations” (any type, 10% of malformations)

Arteriovenous Malformations, Cavernous Malformations, and Dural Fistulas

Table 13. Comparison of Pathoetiology, Clinical Presentation, and Treatment of Arteriovenous Malformations, Cavernous Malformations, and Dural Fistula’s

	Arteriovenous Malformation	Cavernous Malformations	Dural Fistulas
Definition	Tangle of abnormal vessels/arteriovenous shunts, with no intervening capillary beds or brain parenchyma; usually congenital	Benign vascular hamartoma consisting of irregular sinusoidal vascular channels located within the brain without intervening neural tissue or associated large arteries/veins Several genes now described: CCM1, CCM2, CCM3	Fistula’s connecting dural arteries to dural veins or the dural sinus Frequently described to occur at the transverse and cavernous sinuses, but can be found at every cranial dural sinus Hypothesized to be related to venous sinus thrombosis formation, and subsequent microvascular shunt formation within the dura between arteries and veins
Epidemiology	Prevalence ~0.14%, M:F = 2:1, average age at diagnosis = 33 yr 15-20% of patients with hereditary hemor-rhagic telangiectasia (Osler-Weber-Rendu syndrome) will have cerebral AVMs	Prevalence of 0.1-0.2%, both sporadic and hereditary forms described	Unknown true incidence Constitute 10-15% of all intracranial vascular abnormalities
Clinical Features	Hemorrhage (40-60%): small AVMs are more likely to bleed due to direct high pressure AV connections Seizures (50%): more common with larger AVMs Mass effect Focal neurological signs secondary to ischemia (high flow → “steal phenomena”) Localized headache, increased ICP Bruit (especially with dural AVMs) May be asymptomatic (“silent”)	Seizures (60%), progressive neurological deficit (50%), hemorrhage (20%), H/A Often an incidental finding Hemorrhage risk less than AVM, usually minor bleeds	Asymptomatic, pulsatile tinnitus if involving sigmoid or transverse sinuses, bruits, headache. Carotid cavernous involvement classically produces proptosis, chemosis, and bruits. Symptoms of SAH, SDH, or ICH
Investigations	MRI (flow void), MRA Angiography (7% will also have one or more associated aneurysms)	T2WI MRI (non-enhancing) gradient echo sequencing (best for diagnosis)	Non-enhanced CT to r/o hemorrhage MRI; however, this does not demonstrate the arterial supply to the fistula Angiography remains the gold standard
Treatment	Decreases risk of future hemorrhage and seizure Surgical excision is treatment of choice even in Spetzler-Martin Grades I–II with general good health SRS (stereotactic radiosurgery) is preferred for small (<3 cm) or very deep lesions Endovascular embolization (glue, balloon) can be curative (5%) or used as adjuvant to surgery or SRS in larger lesions Conservative (e.g. palliative embolization, seizure control if necessary)	Surgical excision Only appropriate for symptomatic lesions that are surgically accessible (supratentorial lesions are less likely to bleed than infraten-torial lesions)	Approach is dependent on size, location and symptoms, and includes: Conservative treatment Neuroradiological endovascular interventions Radiation therapy Surgery Combination of the above
Prognosis	10% mortality, 30-50% morbidity (serious neurological deficit) per bleed Risk of major bleed in untreated AVMs: 2-4% per year		8.1% annual risk of hemorrhage 6.9% annual risk for non-hemorrhagic neurological deficit 10.4% mortality rate

A. T2 weighted imaging MRI
B. Gradient echo sequencing MRI

Clinical Course Of Untreated Cerebral Cavernous Malformations (CCM)
Lancet Neurol. 2015 Dec 1. pii: S1474-4422(15)00303-8

Summary: (1) mode of clinical presentation and (2) CCM location are independently associated with intracranial hemorrhage (ICH) within 5 years of CCM diagnosis. The risk of recurrent hemorrhage from a CCM is greater than the risk of first event and declines over 5 years.

Methods: collected individual patient data from investigators of published studies on MEDLINE and Embase since inception until April 2015 (7 cohorts from 6 studies, n=1620) on clinical course from CCM diagnosis until first CCM treatment or last available follow-up.

Results: 204 of 1620 experienced ICH during 5187 person-year follow-up (Kaplan-Meier estimated 5-year risk 15.8%, 95% CI 13.7-17.9). ICH within 5 years of CCM was associated with clinical presentation with ICH or focal neurological deficit without brain imaging evidence of recent hemorrhage (vs. other presentations; HR 5.6, 95% CI 3.2-9.7) and with brainstem CCM location (vs. other locations; HR 4.4, 95% CI 2.3-8.6).

Cerebrospinal Fluid Fistulas

Etiology

- cranial or spinal
- traumatic: after head trauma, iatrogenic (post-transsphenoidal surgery, post skull base surgery)
- nontraumatic: high pressure (hydrocephalus, tumour), normal pressure (bone erosion secondary to infection, congenital defect)

Clinical Features

- otorrhea or rhinorrhea (clear fluid)
- low pressure headaches (worse when sitting up)
- confirmatory testing for CSF: β transferrin test, quantitative glucose analysis of fluid, "ring sign", "reservoir sign"

Investigations

- CT (detect pneumocephalus, fractures, skull base defects), water contrast CT cisternography

Treatment

- lower ICP (avoid straining, acetazolamide to reduce CSF production, modest fluid restriction)
- persistent leak: may require continuous lumbar drainage via percutaneous catheter
- surgical indications: traumatic leak lasting >2 wk, spontaneous leaks, delayed onset of leak after trauma or surgery, leaks complicated by meningitis

Suspect CSF fistula in patients with otorrhea or rhinorrhea after head trauma or recurrent meningitis

Ring Sign: If CSF is stringed with blood. Allow CSF to drain onto the surrounding sheets; positive if clear in centre with surrounding blood coloured ring (double ring sign)

Reservoir sign: Gush of CSF leaks out in certain head positions; i.e. teapot sign (not specific or sensitive)

EXTRACRANIAL PATHOLOGY

Approach to Limb/Back Pain

- see [Orthopedics, OR23](#)

Extradural Lesions

Stereotactic Radiosurgery For Cavernous Malformations (CM)
J Neurosurg. 2010 Oct; 113(4):691-9

Summary: stereotactic radiosurgery is a safe intervention for CMs, with advantages of reducing rebleed risks in patients with repeated pretreatment hemorrhage. Treating CMs with single bleed is less clear. However, the morbidity of repeated hemorrhage outweighs any radiosurgery related morbidity and early active management of deep-seated CMs should be considered.

Methods: retrospective analysis of 113 patients with 79 brainstem and 39 thalamic/basal ganglia CMs treated with gamma knife surgery.

Results:

1. Patients with multiple symptomatic hemorrhages before radiosurgery (n=41): rebleed rate decreased from 30.5% per lesion to 15% for the first 2 years after radiosurgery and 2.4% subsequently. Pretreatment multiple bleeds led to permanent deficits in 72% of these patients.
2. Patients with ≤ 1 symptomatic bleed before radiosurgery (n=77): natural history is uncertain due to short period between presenting bleed and treatment (median 1 year). Rate of hemorrhage was 5.1% for the first 2 years and 1.3% subsequently. Pretreatment hemorrhages led to permanent deficits in 43% of these patients (significantly lower than multiple-bleeds group, $p < 0.001$)
3. Permanent adverse radiation effects were rare (7.3%) and minor in both groups.
4. Posttreatment hemorrhages led to persistent deficits in 7.3% of patients.

RED FLAGS for Back Pain
BACK PAIN

Bowel/Bladder (retention or incontinence)

Anesthesia (saddle)

Constitutional symptoms

"K"ronic disease

Parasthesia

Age >50 yr or <20 yr

IV drug use

Neuromotor deficits

Cauda Equina

- Urinary retention or incontinence, fecal incontinence or loss of anal sphincter tone, saddle anesthesia, uni/bilateral, leg weakness/pain

Malignancy

- Age >50 yr, previous Hx of cancer, pain unrelieved by bed rest, constitutional symptoms

Infection

- Increased ESR, IV drug use, immunosuppressed, fever

Compression Fracture

- Age >50 yr, trauma, prolonged steroid use

AXIAL SECTION OF THORACIC SPINE

- Post. circulation
- Ant. circulation

Figure 22. Vascular supply of spinal cord

Root Compression

- radiculopathy is a pain and/or sensorimotor deficit syndrome that involves compression of a nerve root. Nerve compression generally occurs as a result of disc herniation, degenerative disc diseases (spondylosis), instability and rarely, masses
- patients generally present with referred pain, sensory changes (numbness and/or tingling) or weakness. Whereas patients might sometime describe sensory changes in a dermatomal distribution, the referred pain will not be in a dermatomal distribution. The areas of pain and altered sensorium may be incongruent
- muscle innervation has less overlap than sensory innervation and hence is a better predictor of level of pathology

Differential Diagnosis

- herniated disc
- neoplasm (neurofibroma, schwannoma)
- synovial cyst, abscess
- hypertrophic bone/spur

Cervical Disc Syndrome

Etiology

- nucleus pulposus herniates through annulus fibrosus and impinges upon nerve root, most commonly at C6-C7 (C7 root)

Clinical Features

- pain in arm follows nerve root distribution, worse with neck extension, ipsilateral rotation, and lateral flexion (all compress the ipsilateral neural foramen)
- LMN signs and symptoms
- central cervical disc protrusion causes myelopathy as well as nerve root deficits

Investigations

- if red flags: C-spine x-ray, CT, MRI (imaging of choice)
- only consider EMG, nerve conduction studies if diagnosis uncertain and presenting more as peripheral nerve issue

Treatment

- **conservative**
 - no bedrest unless severe radicular symptoms
 - activity modification, patient education (reduce sitting, lifting)
 - physiotherapy, exercise programs focus on strengthening core muscles
 - analgesics, NSAIDs are more efficacious
 - avoid cervical manipulation, like traction
- **surgical indications**
 - anterior cervical discectomy is usual approach
 - intractable pain despite adequate conservative treatment for >3 mo
 - progressive neurological deficit

Prognosis

- 95% improve spontaneously in 4-8 wk

Table 14. Lateral Cervical Disc Syndromes

	C4-5	C5-6	C6-7	C7-T1
Root Involved	C5	C6	C7	C8
Incidence	2%	19%	69%	10%
Sensory	Shoulder	Thumb	Middle finger	Ring finger, 5th finger
Motor	Deltoid, biceps, supraspinatus	Biceps	Triceps	Digital flexors, intrinsic
Reflex	No change	Biceps, brachioradialis	Triceps	Finger jerk (Hoffmann's sign)

Sensory Fibres

Fasciculus gracilis/cuneatus: proprioception, fine touch, vibration
Spinothalamic tract: pain and temperature

Motor Fibres

Corticospinal tract: skilled movements

Disc herniations impinge the nerve root at the level **below** the interspace (i.e. C5-6 disc affects the C6 nerve root)

Cervical Spondylosis

Definition

- progressive degenerative process of cervical spine leading to canal stenosis – congenital spinal stenosis, degeneration of intervertebral discs, hypertrophy of lamina, dura, or ligaments, spondylosis, subluxation, altered mobility, telescoping of the spine due to loss of height of vertebral bodies, alteration of normal lordotic curvature
- resultant syndromes: mechanical neck pain, radiculopathy (root compression), myelopathy (spinal cord compression)

Epidemiology

- typically begins at age 40-50, M>F, most commonly at the C5-C6 > C6-C7 levels

Pathogenesis

- any of: disc degeneration/herniation, osteophyte formation, ossification, and hypertrophy of ligaments
- pathophysiology includes static compression, dynamic compression, and vascular compromise

Clinical Features

- insidious onset of mechanical neck pain exacerbated by excess vertebral motion (particularly rotation and lateral bending with a vertical compressive force – Spurling's test)
- the earliest symptoms are gait disturbance and lower extremity weakness or stiffness
- occipital H/A is common
- radiculopathy may involve 1 or more roots, and symptoms include neck, shoulder and arm pain, paresthesias and numbness
- cervical spondylotic myelopathy (CSM) may present with
 - weakness (upper > lower extremity), lower extremity weakness (corticospinal tracts) is most worrisome complaint
 - decreased dexterity, loss of fine motor control
 - sensory changes
 - UMN findings such as hyperreflexia, clonus, and Babinski reflex
 - funicular pain, characterized by burning and stinging ± Lhermitte's sign (lightning-like sensation down the back with neck flexion)

Investigations

- x-ray of cervical spine ± flexion/extension (alignment, fractures)
- MRI most useful for determination of compression of the neural element
- CT is only used for better determination of bony anatomy (i.e. OPLL)
- EMG/nerve conduction studies reserved for peripheral nerve investigation

Treatment

- nonsurgical: prolonged immobilization with cervical bracing (limit movement to minimize cumulative trauma to spinal cord), bed rest, anti-inflammatory medications
- surgical: anterior approach (anterior cervical discectomy or corpectomy), posterior approach (decompressive cervical laminectomy)
- In multilevel CSM, an anterior approach is associated with better postoperative neural function but has a higher complication and reoperation rate than the posterior group
- surgical indications: myelopathy with motor impairment, progressive neurologic impairment, intractable pain
- complete remission almost never occurs. Surgical decompression may stop progression of disease

Cervical spondylotic myelopathy is the most common cause of spinal cord impairment

Clinical Grading Scores to Assess CSM

- mJOA
- Nurick Grade
- Neck Disability Index

Efficacy and Safety of Surgical Decompression in Patients with Cervical Spondylotic Myelopathy: Results of the AOSpine North America Prospective Multi-centre Study

J Bone Joint Surg Am. 2013 Sep 18;95(18):1651-8

Purpose: Evaluate impact of surgical decompression on functional, QOL, and disability outcomes 1-yr post-surgery in patients with cervical spondylotic myelopathy.

Methods: 278 patients with mild to severe symptomatic cervical spondylotic myelopathy and MRI evidence of spinal cord compression were followed for 1 yr following surgical decompression. Outcomes (mJOA score, Nurick grade, Neck Disability Index, Short Form-36v2) were compared to preoperative values. Treatment-related complication data was collected.

Results: There was significant improvement ($P < 0.05$) from baseline in mJOA score, Nurick grade, NDI score, and all SF-36v2 health dimensions other than general health. 18.7% of patients experienced complications with no significant differences among the severity groups.

Conclusion: Surgical decompression of cervical spondylotic myelopathy is associated with improved function, disability, and QOL outcomes at 1 yr.

Lumbar Disc Syndrome

Etiology

- posteriolaterally herniated disc compressed nerve root exiting BELOW the level of the disc or the traversing nerve root
- far lateral disc herniation compressed nerve root AT the level of the disc or the exiting nerve root
- central herniation causes cauda equina or lumbar stenosis (neurogenic claudication)

Clinical Features

- initially back pain, then leg pain > back pain
- limited back movement (especially forward flexion) due to pain
- motor weakness, dermatomal sensory changes, decreased reflexes
- exacerbation with valsalva; relief with flexing the knee or thigh
- nerve root tension signs
 - straight leg raise (SLR, Lasegue's test) or crossed SLR (pain should occur at less than 60°) suggests L5, S1 root involvement
 - femoral stretch test suggests L2, L3, or L4 root involvement

Figure 23. T2 weighted MRI of lumbar disc herniation

Investigations

- MRI is modality of choice
- x-ray spine (only to rule out other lesions), CT (bony anatomy)
- myelogram and post-myelogram CT (only if MRI is contraindicated)

Treatment

- conservative (same as cervical disc disease)
- surgical indications: same as cervical disc + cauda equina syndrome

Prognosis

- 95% improve spontaneously within 4-8 wk
- those who do not improve with conservative treatment achieve symptom relief quicker with surgery than continuation of conservative management; however, the long-term outcome after surgery is comparable to conservative therapy
- do not follow patients with serial MRIs; clinical status is more important at guiding management

Table 15. Lateral Lumbar Disc Syndromes

	L3-4	L4-5	L5-S1
Root Involved	L4	L5	S1
Incidence	<10%	45%	45%
Pain	Femoral pattern	Sciatic pattern	Sciatic pattern
Sensory	Medial leg	Dorsal foot to hallux	
Lateral leg	Lateral foot		
Motor	Tibialis anterior (dorsiflexion)	Extensor hallucis longus (hallux extension)	Gastrocnemius, soleus (plantar flexion)
Reflex	Patellar	Medial hamstrings	Achilles

Table 16. Differentiating Conus Medullaris Syndrome from Cauda Equina Syndrome

	Conus Medullaris Syndrome	Cauda Equina Syndrome
Onset	Sudden, bilateral	Gradual, unilateral
Spontaneous Pain	Rare, if present usually bilateral, symmetric in perineum or thighs	Severe, radicular type: in perineum, thighs, legs, back, or bladder
Sensory Deficit	Saddle; bilateral and symmetric; sensory dissociation	Saddle; no sensory dissociation; may be unilateral and asymmetric
Motor Deficit	Symmetric; paresis less marked; fasciculations may be present	Asymmetric; paresis more marked; atrophy may be present; fasciculations rare
Reflexes	Only ankle jerk absent (preserved knee jerk)	Knee and ankle jerk may be absent
Autonomic Symptoms (bladder dysfunction, impotence, etc.)	Urinary retention and atonic anal sphincter prominent early; impotence frequent	Sphincter dysfunction presents late; impotence less frequent

Treatment Of Lumbar Disc Herniation: Evidence-Based Practice

Int J Gen Med. 2010; 3: 209-214

Objective: To determine the best treatment for lumbar disc herniations

Results: For patients failing six weeks of conservative care, the current literature supports surgical intervention or prolonged conservative management as appropriate treatment options for lumbar radiculopathy in the setting of disc herniation. Surgical intervention may result in more rapid relief of symptoms and restoration of function.

Conclusions: While surgery appears to provide more rapid relief, many patients will gradually get better with continued non-operative management; thus, patient education and active participation in decision-making is vital.

Magnetic Resonance Imaging in Follow-Up Assessment of Sciatica

NEJM 2013;368:999-1007

Background: Follow-up MRI is a controversial method for monitoring sciatica in patients with known lumbar-disc herniation.

Methods: Participants (n=283) were recruited from a simultaneous, parallel, randomized study comparing surgery and conservative care for sciatica (the Sciatica Trial). MRI and clinical assessment were undertaken pre-treatment and 1 yr post-treatment randomized to visualize disc herniation and evaluate outcome.

Results: At 1 yr, disc herniation was visible in 35% with a favourable outcome (complete, or nearly complete symptom resolution) and in 33% with an unfavourable outcome (p=0.70). A favourable outcome was reported in 85% of patients with disc herniation and 83% without disc herniation (p=0.70).

Conclusions: Anatomical abnormalities visible on repeated MRI 1 yr after treatment for sciatica due to lumbar-disc herniation could not distinguish patients with resolution of their symptoms from patients still experiencing symptoms.

Causes of Cauda Equina Syndrome

- Lumbar disc herniation
- Spinal stenosis
- Spinal tumour
- Epidural abscess
- Hematoma
- Trauma

Cauda Equina Syndrome

Etiology

- compression or irritation of lumbosacral nerve roots below conus medullaris (below L2 level)
- decreased space in the vertebral canal below L2
- common causes: herniated disc ± spinal stenosis, vertebral fracture, and tumour

Clinical Features

- usually acute (develops in less than 24 h); rarely subacute or chronic
- motor (LMN signs)
 - weakness/paraparesis in multiple root distribution
 - reduced deep tendon reflexes (knee or ankle)
- autonomic
 - urinary retention (or overflow incontinence) and/or fecal incontinence due to loss of anal sphincter tone
- sensory
 - low back pain radiating to legs (sciatica) aggravated by Valsalva maneuver and by sitting; relieved by lying down
 - bilateral sensory loss or pain: depends on the level affected
 - saddle area (S2-S5) anesthesia
 - sexual dysfunction (late finding)

Investigations

- urgent MRI to confirm compression of S2-S3-S4 nerve root by a large disc herniation
- post-void residual very helpful to determine if true retention is present; volumes controversial but anything over 250 cc in a healthy individual is cause for concerns

Treatment

- surgical decompression (<48 h) to preserve bowel, bladder, and sexual function, and/or to prevent progression to paraplegia
- Consult radiation oncology for urgent symptomatic management if palliative oncology patient

Prognosis

- markedly improves with surgical decompression
- recovery correlates with function at initial presentation: if patient is ambulatory, likely to continue to be ambulatory; if unable to walk, unlikely to walk after surgery

Lumbar Spinal Stenosis

Etiology

- congenital narrowing of spinal canal combined with degenerative changes (herniated disc, hypertrophied facet joints, and ligamentum flavum)

Clinical Features

- gradually progressive back and leg pain with standing and walking that is relieved by sitting or lying down (neurogenic claudication – 60% sensitive)
- neurologic exam may be normal, including straight leg raise test

Investigations

- MRI is the optimal investigation to confirm and localize the level of stenosis (unlike nerve root compression which can be localized with clinical exam)

Treatment

- conservative: NSAIDs, analgesia
- surgical: laminectomy with root decompression (the role of fusion may need to be considered if the amount of bone removed with the laminectomy results in destabilization)

Neurogenic Claudication

Etiology

- ischemia of lumbosacral nerve roots secondary to vascular compromise and increased demand from exertion, often associated with lumbar stenosis

Clinical Features

- dermatomal pain/paresthesia/weakness of buttock, hip, thigh, or leg initiated by standing or walking
- slow relief with postural changes (sitting >30 min), NOT simply exertion cessation
- induced by variable degrees of exercise or standing
- may be elicited with lumbar extension, but may not have any other neurological findings, no signs of vascular compromise (e.g. ulcers, poor capillary refill, etc.)

Investigations

- bicycle test may help distinguish neurogenic claudication (NC) from vascular claudication (the waist-flexed individuals on the bicycle with NC can last longer)

Treatment

- same as for lumbar spinal stenosis

Surgical vs. Non-Operative Treatment For Lumbar Spinal Stenosis Four-Year Results Of The Spine Outcomes Research Trial (SPORT)

Spine 2010. 35(14): 1329-1338

Objective: To compare 4 year outcomes of surgery to non-operative care for spinal stenosis.

Methods: Surgical candidates from 13 centres in 11 U.S. states with at least 12 weeks of symptoms and confirmatory imaging were enrolled in a randomized cohort (RC) or observational cohort (OC). Treatment was standard decompressive laminectomy or standard non-operative care. Primary outcomes were SF-36 bodily pain (BP) and physical function (PF) scales and the modified Oswestry Disability index (ODI) assessed at 6 weeks, 3 months, 6 months and yearly up to 4 years.

Conclusions: Patients with symptomatic spinal stenosis treated surgically compared to those treated non-operatively maintain substantially greater improvement in pain and function through four years.

Key Features of Neurogenic vs. Vascular Claudication

Neurogenic Claudication: dermatomal distribution with positional relief occurring over minutes

Vascular Claudication: sclerotomal distribution with relief occurring with rest over seconds

Intradural Intramedullary Lesions

Syringomyelia (Syrinx)

Definition

- cystic cavitation of the spinal cord
- presentation is highly variable, usually progresses over months to years
- initially pain, weakness; later atrophy and loss of pain and temperature sensation

Etiology

- 70% are associated with Chiari I malformation, 10% with basilar invagination
- post-traumatic
- tumour
- tethered cord

Clinical Features

- nonspecific features for any intramedullary spinal cord pathology
 - initially pain, weakness, atrophy, then loss of pain and temperature (spinothalamic tract) in upper extremities (central syrinx) with progressive myelopathy over years
 - sensory loss with preserved touch and proprioception (DCML) in a band-like distribution at the level of cervical syrinx
 - dysesthetic pain often occurs in the distribution of the sensory loss
 - LMN arm/hand weakness or wasting
 - painless neuropathic arthropathies (Charcot’s joints), especially in the shoulder and neck due to loss of pain and temperature sensation

Investigations

- MRI is best method, myelogram with delayed CT

Treatment

- treat underlying cause (e.g. posterior fossa decompression for Chiari I, surgical removal of tumour if causing a syrinx)
- rarely does the syrinx need to be shunted, only when progressive and size allows for insertion of tube

Figure 24. T1 weighted MRI of syringomyelia

Spinal Cord Syndromes

Complete Spinal Cord Lesion

- bilateral loss of motor/sensory and autonomic function at ≥4 segments below lesion/injury, with UMN signs
- about 3% of patients with complete injuries will develop some recovery within 24 h, beyond 24 h, no distal function will recover

Incomplete Spinal Cord Lesion

- any residual function at ≥4 segments below lesion
- signs include sensory/motor function in lower limbs and “sacral sparing” (perianal sensation, voluntary rectal sphincter contraction)

Table 17. Comparison Between Incomplete Spinal Cord Lesion Syndromes

Syndrome	Etiology	Motor	Sensory
Brown-Séquard	Hemisecion of cord	Ipsilateral LMN weakness at the lesion Ipsilateral UMN weakness below the lesion	Ipsilateral loss of vibration and proprioception Contralateral loss of pain and temperature Preserved light touch
Anterior Cord	Anterior spinal artery compression or occlusion	Bilateral LMN weakness at the lesion Bilateral UMN weakness below the lesion Urinary retention	Preserved vibration and proprioception Bilateral loss of pain and temperature Preserved light touch
Central Cord (most common)	Syringomyelia, tumours, spinal hyperextension injury	Bilateral motor weakness: Upper limb weakness (LMN lesion) > Lower limb weakness (UMN lesion) Urinary retention	Variable bilateral suspended sensory loss Loss of pain and temperature > loss of vibration and proprioception
Posterior Cord	Posterior spinal artery infarction, trauma	Preserved	Bilateral loss of vibration, proprioception, light touch at and below the lesion Preserved pain and temperature

American Spinal Injury Association Impairment Scale

Grade	Description
A	complete, no motor/sensory below neurological level including S4/5
B	incomplete, sensory but not motor function preserved below neurological level including S4/5
C	incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade <3
D	incomplete, motor function preserved below neurological level, and more than half of the key muscles below neurological level have a muscle grade ≥3
E	normal motor and sensory function

Figure 25. Spinal cord lesion syndromes

Peripheral Nerves

- see [Neurology, N36](#)

Classification

Table 18. Seddon's Classification of Peripheral Nerve Injury

Nerve Injury	Description	Recovery
Neurapraxia (class I)	Axon structurally intact but fails to function	Within hours to months (average 6-8 wk)
Axonotmesis (class II)	Axon and myelin sheath disrupted but endoneurium and supporting structures intact → Wallerian degeneration of axon segment distal to injury	Spontaneous axonal recovery at 1 mm/d, max at 1-2 yr
Neurotmesis (class III)	Nerve completely transected	Need surgical repair for possibility of recovery

Etiology

- ischemia
- nerve entrapment – nerve compressed by nearby anatomic structures, often secondary to localized, repetitive mechanical trauma with additional vascular injury to nerve

Investigations

- clinical exam: power, sensation, reflexes, localization via Tinel's sign (paresthesias elicited by tapping along the course of a nerve)
- electrophysiological studies: EMG, nerve conduction study (assess nerve integrity and monitoring recovery after 2-3 wk post-injury)
- labs: blood work (e.g. CBC, TSH, Vitamin B12), CSF
- imaging: C-spine, chest/bone x-rays, myelogram, CT, magnetic resonance neurography, angiogram if vascular damage is suspected

Treatment

- early neurosurgical consultation if injury is suspected

Table 19. Treatment by Injury Type

Injury	Treatment
Entrapment	Conservative: prevent repeated stress/injury, physiotherapy, NSAIDs, local anesthesia/steroid injection Surgical: nerve decompression ± transposition for progressive deficits, muscle weakness/atrophy, failure of medical management
Stretch/contusion	Follow-up clinically for recovery; exploration if no recovery in 3 mo
Axonotmesis	If no evidence of recovery, resect damaged segment Prompt physical therapy and rehabilitation to increase muscle function, maintain joint ROM, maximize return of useful function Recovery usually incomplete
Neurotmesis	Surgical repair of nerve sheath unless known to be intact (suture nerve sheaths directly if ends approximate or nerve graft (usually sural nerve)) Clean laceration: early exploration and repair Contamination or associated injuries: tag initially with nonabsorbable suture, reapproach within 10 d

Complications

- neuropathic pain: with neuroma formation
- complex regional pain syndrome: with sympathetic nervous system involvement

SPECIALTY TOPICS

Neurotrauma

Trauma Management (see [Emergency Medicine, ER7](#))

Indications for Intubation in Trauma

1. depressed LOC (patient cannot protect airway): usually GCS ≤8
2. need for hyperventilation
3. severe maxillofacial trauma: patency of airway is doubtful
4. need for pharmacologic paralysis for evaluation or management
 - if basal skull fracture suspected, avoid nasotracheal intubation as may inadvertently enter brain
 - note: intubation prevents patient's ability to verbalize for determining GCS

Figure 26. Peripheral nerve structure

Glasgow Coma Scale

Eye Response	Verbal Response	Motor Response
4 spontaneous	5 oriented	6 obeys commands
3 opens eyes to pain	4 confused	5 localizes to pain voice
2 opens eyes to pain	3 inappropriate words	4 withdraws from pain
1 no eye opening	2 incomprehensible sounds	3 flexion to pain (decorticate posturing)
	1 no response	2 extension to pain (decerebrate posturing)
	T intubated	1 no response

Best response for each component recorded individually (e.g. E3V3M5)
 ≥13 is mild injury; 9-12 is moderate injury; ≤8 is severe injury

Trauma Assessment

Initial Management

ABCs of Trauma Management

- see [Emergency Medicine, ER2](#)

NEUROLOGICAL ASSESSMENT

Mini-History

- period of LOC, post-traumatic amnesia, loss of bowel/bladder control, loss of sensation, weakness, type of injury/accident

Neurological Exam

- GCS
- head and neck (lacerations, bruises, basal skull fracture signs, facial fractures, foreign bodies)
- spine (palpable deformity, midline pain/tenderness)
- eyes (pupillary size and reactivity)
- brainstem (breathing pattern, CN palsies)
- cranial nerve exam
- motor exam, sensory exam (only if GCS is 15), reflexes
- sphincter tone, saddle sensation
- record and repeat neurological exam at regular intervals

Investigations

- spinal injury precautions (cervical collar) are continued until C-spine is cleared
- C,T,L-spine x-rays
 - AP, lateral, odontoid views for C-spine (must see from C1 to T1; swimmer's view if necessary) or CT
 - rarely done: oblique views looking for pars interarticularis fracture ("Scottie dog" sign)
- CT head and upper C-spine (whole C-spine if patient unconscious) look for fractures, loss of mastoid or sinus air spaces, blood in cisterns, pneumocephalus
- cross and type, ABG, CBC, drug screen (especially alcohol)
- chest and pelvic x-ray as indicated

TREATMENT

Treatment for Minor Head Injury (GCS 13-15)

- observation over 24-48 h
- wake every hour
- judicious use of sedatives or pain killers during monitoring period
- outpatient: advise patients to undergo stepwise approach to return to play and return to school (include references for these new recommendations)

Treatment for Severe Head Injury (GCS ≤ 8)

- clear airway and ensure breathing (if GCS ≤ 8 , intubate)
- secure C-spine
- maintain adequate BP
- monitor for clinical deterioration
- monitor and manage increased ICP if present (see [Herniation Syndromes, NS7](#))

Admission required if:

- skull fracture (indirect signs of basal skull fracture, see [Head Injury, NS32](#))
- confusion, impaired consciousness, concussion with >5 min amnesia
- focal neurological signs, extreme H/A, vomiting, seizures
- unstable spine
- use of alcohol
- poor social support

- Never do lumbar puncture in head injury unless increased ICP has been ruled out
- All patients with head injury have C-spine injury until proven otherwise
- Suspect hematoma in alcoholic-related injuries
- Low BP after head injury means injury elsewhere
- Must clear spine both radiologically AND clinically

Assessment of Spine CT/X-Ray (Parasagittal View)

ABCDS

Alignment (columns: anterior vertebral line, posterior vertebral line, spinolaminar line, posterior spinous line)

Bone (vertebral bodies, facets, spinous processes)

Cartilage

Disc (disc space and interspinous space)

Soft tissues

Comparative Effectiveness of Using Computed Tomography Alone to Exclude Cervical Spine Injuries in Obtunded or Intubated Patients: Meta-Analysis of 14,327 Patients with Blunt Trauma
J Neurosurg 2011;115:541-549

Purpose: To determine the effectiveness of helical CT alone (vs. CT and adjuvant imaging such as MR) to diagnose acute unstable cervical spine injury following blunt trauma.

Results: 17 studies with 14,327 patients total. Sensitivity and specificity for modern CT were both $>99.9\%$ (95% CI 0.99 -1.00 for both). The negative predictive value of a normal CT scan was 100% (95% CI 0.96-1.00) and accuracy was not affected by the global severity of injury, CT slice thickness, or study quality.

Conclusions: CT alone is sufficient to detect unstable cervical spine injuries in trauma patients and adjuvant imaging is unnecessary with a negative CT scan result. Consequently, if a CT scan is negative for acute injury, the cervical collar may be removed from obtunded or intubated trauma patients.

Head Injury

Epidemiology

- M:F = 2-3:1

Pathogenesis

- acceleration/deceleration: contusions, subdural hematoma, axon and vessel shearing/mesencephalic hematoma
- impact: skull fracture, concussion, epidural hematoma
- penetrating: worse with high velocity and/or high missile mass
 - low velocity: highest damage to structures on entry/exit path
 - high velocity: highest damage away from missile tract

Scalp Injury

- rich blood supply
- considerable blood loss (vessels contract poorly when ruptured)
- minimal risk of infection due to rich vascularity

Skull Fractures

- depressed fractures: double density on skull x-ray (outer table of depressed segment below inner table of skull), CT with bone window is gold standard
- simple fractures (closed injury): no need for antibiotics, no surgery
- compound fractures (open injury): increased risk of infection, surgical debridement within 24 h is necessary
 - internal fractures into sinus may lead to meningitis, pneumocephalus
 - risk of operative bleed may limit treatment to antibiotics
- basal skull fractures: not readily seen on x-ray, rely on clinical signs
 - retroauricular ecchymoses (Battle's sign)
 - periorbital ecchymoses (raccoon eyes)
 - hemotympanum
 - CSF rhinorrhea, otorrhea (suspect CSF if halo or target sign present); suspect with Lefort II/III midface fracture

Cranial Nerve Injury

- most traumatic causes of cranial nerve injury do not warrant surgical intervention
- surgical intervention
 - CN II: local eye/orbit injury
 - CN III, IV, VI: if herniation secondary to mass
 - CN VIII: repair of ossicles
- CN injuries that improve
 - CN I: recovery may occur in a few months; most do not improve
 - CN III, IV, VI: majority recover
 - CN VII: recovery with delayed lesions
 - CN VIII: vestibular symptoms improve over weeks, deafness usually permanent (except when resulting from hemotympanum)

Arterial Injury

- e.g. carotid-cavernous (C-C) fistula, carotid/vertebral artery dissection

Intracranial Bleeding

- see *Blood*, NS16 and *Cerebrovascular Disease*, NS18

Brain Injury

Primary Impact Injury

- mechanism of injury determines pathology: penetrating injuries, direct impact
 - low velocity: local damage
 - high velocity: distant damage possible (due to wave of compression), concussion
- concussion: a trauma-induced alteration in mental status
 - American Academy of Neurology (AAN) Classification
 - no parenchymal abnormalities on CT
- coup (damage at site of blow) and contrecoup (damage at opposite site of blow) (Figure 27)
 - acute decompression causes cavitation followed by a wave of acute compression
- contusion (hemorrhagic)
 - high density areas on CT ± mass effect
 - commonly occurs with brain impact on bony prominences (inferior frontal lobe, pole of temporal lobe)
- diffuse axonal injury/shearing
 - wide variety of damage results
 - may tear blood vessels (hemorrhagic foci)
 - often the cause of decreased LOC if no space-occupying lesion on CT

The Canadian CT Head Rule for Patients with Minor Head Injury

Lancet 2001;357:1391-1396

CT Head is only required for patients with minor head injuries with any one of the following:

High Risk (for neurological intervention)

- GCS score <15 at 2 h after injury.
- Suspected open or depressed skull fracture.
- Any sign of basal skull fracture (hemotympanum, "raccoon" eyes, cerebrospinal fluid otorrhea/rhinorrhoea, Battle's sign).
- Vomiting ≥2 episodes.
- Age ≥65 yr.

Medium Risk (for brain injury on CT)

- Amnesia after impact >30 min.
- Dangerous mechanism (pedestrian struck by motor vehicle, occupant ejected from motor vehicle, fall from height >3 feet or five stairs).

Minor Head Injury is defined as witnessed loss of consciousness, definite amnesia, or witnessed disorientation in a patient with a GCS score of 13-15.

Figure 27. CT showing coup-contrecoup injury

AAN Classification

- Grade 1: altered mental status <15 min
- Grade 2: altered mental status >15 min
- Grade 3: any loss of consciousness

SIADH → hyponatremia
DI → hypernatremia

Secondary Pathologic Processes

- same subsequent biochemical pathways for each traumatic etiology
- delayed and progressive injury to the brain due to
 - high glutamate release → NMDA receptor activation → cytotoxic cascade
 - cerebral edema
 - intracranial hemorrhages
 - ischemia/infarction
 - raised ICP, intracranial HTN
 - hydrocephalus

Extracranial Conditions

- hypoxemia
 - due to trauma to the chest, upper airway, brainstem
 - extremely damaging to vulnerable brain cells
 - leads to ischemia, raised ICP
- hypercarbia
 - leads to raised ICP (secondary to vasodilation)
 - systemic hypotension
 - caused by blood loss (e.g. ruptured spleen)
 - loss of cerebral autoregulation leads to decreased CPP, ischemia
- hyperpyrexia
 - leads to increased brain metabolic demands → ischemia
- fluid and electrolyte imbalance
 - iatrogenic (most common)
 - SIADH caused by head injury
 - diabetes insipidus (DI)
 - may lead to cerebral edema and raised ICP
- coagulopathy

Intracranial Conditions

- raised ICP due to traumatic cerebral edema OR traumatic intracranial hemorrhage

Brain Injury Outcomes

- mildly traumatic (GCS 13-15): post-concussive symptoms: H/A, fatigue, dizziness
- nausea, blurred vision, diplopia, memory impairment, tinnitus, irritability, low concentration; 50% at 6 wk, 14% at 1 yr
- moderately traumatic (GCS 9-12): proportional to age (>40) and CT findings; 60% good recovery, 26% moderately disabled, 7% severely disabled, 7% vegetative/dead
- severe (GCS ≤8): difficult to predict, correlates with post-resuscitation GCS (especially motor) and age

Late Complications of Head/Brain Injury

- seizures: 5% of head injury patients develop seizures
 - incidence related to severity and location of injury (increased with local brain damage or intracranial hemorrhage)
 - post-traumatic seizure may be immediate, early, or late
 - presence of early (within first wk) post-traumatic seizure raises incidence of late seizures
- meningitis: associated with CSF leak from nose or ear
- hydrocephalus: acute hydrocephalus or delayed normal pressure hydrocephalus (NPH)
- Post-Concussion Syndrome (PCS)/neuro-psychiatric effects

Spinal Cord Injury

- see [Orthopedics](#), [OR22](#) and [Emergency Medicine](#), [ER9](#)

NEUROGENIC AND SPINAL SHOCK

1. neurogenic shock: hypotension that follows SCI (sBP usually ≤80 mmHg) caused by
 - interruption of sympathetics (unopposed parasympathetics) below the level of injury
 - loss of muscle tone due to skeletal muscle paralysis below level of injury → venous pooling (relative hypovolemia)
 - blood loss from associated wounds (true hypovolemia)
2. spinal shock: transient loss of all neurologic function below the level of the spinal cord injury, causing flaccid paralysis and areflexia for variable periods

Whiplash-Associated Disorders

- definition: traumatic injury to the soft tissue structures in the region of the cervical spine due to hyperflexion, hyperextension, or rotational injury to the neck

Concussion Grades

AAN Grade	Management Options
1	Examine 15 min for amnesia and other symptoms Return to normal activity if symptoms clear within 15 min
2	Remove from activity for 1 d, then re-examine CT or MRI if H/A or other symptoms worsen or last >1 wk Return to normal activity after 1 wk without symptoms
3	Emergent neurological exam + imaging; if initial exam is normal, may go home with close follow-up Admit if any signs of pathology or persistent abnormal mental status CT or MRI if H/A or other symptoms If brief loss of consciousness (<1 min), return to normal activity after 1 wk without symptoms If prolonged loss of consciousness (>1 min), return to normal activity only after 2 wk without symptoms

A Trial of Intracranial-Pressure Monitoring in Traumatic Brain Injury

NEJM 2012;367:2471-2481

Background: ICP monitoring is frequently used to monitor severe traumatic brain injury, but controversy exists over whether it is beneficial.

Methods: Study sample (n=324 patients, ≥13 yr) consisted of those who had severe traumatic brain injury and were being treated in ICU in Bolivia or Ecuador. Patients were randomly assigned to one management group:

1. ICP-monitoring based management.
 2. Management based on imaging and clinical examination.
- Primary outcome was a composite of survival time, impaired consciousness, functional status (at 3, 6 mo), and neuropsychological status (at 6 mo).

Results: No significant difference between management groups based on primary outcome, 6-mo mortality, median length of ICU stay, or occurrence of serious adverse events. However, duration of brain-specific treatments (e.g. use of hyperosmolar fluids or hyperventilation) higher in the imaging-clinical examination group (4.8 d vs. 3.4 d, p=0.002).

Conclusion: Maintaining monitored ICP at 20 mmHg or less is not superior to care based on imaging and clinical examination.

Resolution of spinal shock is indicated by the return of reflexes (most commonly the bulbocavernosus reflex)

Initial Management of SCI

- major causes of death in SCI are aspiration and shock
- the following patients should be treated as having a SCI until proven otherwise:
- all victims of significant trauma
- minor trauma patients with decreased LOC or complaints of neck or back pain, weakness, abdominal breathing, numbness/tingling, or priapism

Stabilization and Initial Evaluation in the Hospital

1. ABCs, immobilization (backboard/head strap), oxygenation, Foley catheter to urometer, temperature regulation
2. hypotension: maintain sBP >90 mmHg with pressors (dopamine), hydration, and atropine
 - DVT prophylaxis
3. monitor CBC/electrolytes
4. focused history (see *Trauma Assessment, NS29*)
5. spine palpation: point tenderness or deformity
6. motor level assessment (including rectal exam for voluntary anal sphincter contraction)
7. sensory level assessment: pinprick, light touch, and proprioception
8. evaluation of reflexes
9. signs of autonomic dysfunction: altered level of perspiration, bowel or bladder incontinence, priapism
10. radiographic evaluation
 - 3 views C-spine x-rays (AP, lateral, and odontoid) to adequately visualize C1 to C7-T1 junction
 - flexion-extension views to disclose occult instability
 - CT scan (bony injuries) typically most trauma centres use CT as the modality of choice for looking at fractures, very sensitive with the high resolution scanners
 - MRI mandatory if neurological deficits (soft tissue injuries)

Medical Management Specific to SCI

- option: methylprednisolone (given within 8 h of injury) this is controversial and you need to confer with Neurosurgery service
- ± decompression in acute, non-penetrating SCI

Pharmacological Therapy for Acute Spinal Cord Injury: Congress of Neurological Surgeons (CNS) and American Association of Neurological Surgeons (AANS) Guidelines

Neurosurgery 2013;72(Suppl 2):93-105

Level I Recommendations

- No Class I or Class II medical evidence supports the use of methylprednisone in the treatment of acute SCI. Several Class II and Class III studies have been published stating inconsistent effects of methylprednisone likely related to random chance or selection bias.
- Administration of GM-1 ganglioside (Sygen) for the treatment of acute SCI is not recommended.

Early vs. Delayed Decompression for Traumatic Cervical Spinal Cord Injury: Results of the Surgical Timing in Acute Spinal Cord Injury Study (STASCIS)

PLoS ONE 2012;7:e32037. doi:10.1371/journal.pone.0032037

Introduction: This study sought to determine the relative effectiveness of early (<24 h after injury) versus late (≥24 h after injury) decompressive surgery following a traumatic cervical spinal cord injury (SCI).

Methods/Population: A prospective cohort study completed in 2002-2009 involving 6 North American institutions. Participants were 16-80 yr with a cervical SCI. Outcomes evaluated were changes in American Spinal Injury Association Impairment Scale (AIS) grade at 6 mo follow-up, complications, and mortality.

Results: Of 313 participants enrolled, 182 underwent early surgery and 131 underwent late surgery. 222 participants were available for follow-up at 6 mo. The odds of at least 2 grade AIS improvement were greater for those who had early surgery compared to those with late surgery (OR = 2.83, 95% CI 1.10, 7.28). Mortality was observed for each group during the first 30 d post injury. No statistically significant differences were observed for complications (p=0.21).

Conclusion: Early decompression surgery following a SCI is safe and associated with higher AIS improvement at 6 mo following injury.

Fractures of the Spine

FRACTURES AND FRACTURE-DISLOCATIONS OF THE THORACIC AND LUMBAR SPINE

- assess ligamentous instability using flexion/extension x-ray views of ± MRI
- thoracolumbar spine unstable if 4/6 segments disrupted (3 columns divided into left and right)
 - anterior column: anterior half of vertebral body, disc, and anterior longitudinal ligament
 - middle column: posterior half of vertebral body, disc, and posterior longitudinal ligament
 - posterior column: posterior arch, facet joints, pedicle, lamina and supraspinous, interspinous, and ligamentum ligaments

Types of Injury

Table 20. Denis Classification of Spinal Trauma

Fracture Type	Description
Compression Fracture (58%)	Produced by flexion Posterior ligament complex (supraspinous and interspinous ligaments, ligamentum flavum, and intervertebral joint capsules) remain intact Fractures are stable but lead to kyphotic deformity
Burst Fracture (17%)	Stable: anterior and middle columns parted with bone retropulsed nearby Hallmark is pedicle widening on AP x-ray Spinal cord (seen on x-ray and CT); posterior column is uninjured Unstable: same as the stable but with posterior column disruption (usually ligamentous)
Flexion Distraction Injury (6%)	Hyperflexion and distraction of posterior elements Middle and posterior columns fail in distraction Classic: Chance = horizontal fracture through posterior arch, pedicles, posterior vertebral body Can be purely ligamentous, i.e. through PLL and disc
Fracture-Dislocation (6%)	Anterior and cranial dislocation of superior vertebral body → 3 column failure Three types: (1) flexion-rotation, (2) flexion-distraction, (3) shear/hyperextension (rare)

Management of Thoracolumbar Injury

- severity and management based on TLICS classification

FRACTURES OF THE CERVICAL SPINE

Types of Injury

Table 21. Fracture Patterns of the Cervical Spine

Fracture Type	Description
C1 Vertebral Fracture (Jefferson fracture)	Vertical compression forces the occipital condyles of the skull down on the C1 vertebra (atlas), pushing the lateral masses of the atlas outward and disrupting the ring of the atlas Also can cause an occipital condylar fracture
Odontoid Fracture	Causes C1 and odontoid of C2 to move independently of C2 body This occurs because Normally C1 vertebra and odontoid of C2 are a single functional unit Alar and transverse ligaments on posterior aspect of odontoid usually remain intact after injury Patients often report a feeling of instability and present holding their head with their hands Type II fracture the most common
C2 Vertebral Fracture (hangman fracture)	Bilateral fracture through the pars interarticularis of C2 with subluxation of C2 on C3 (spondylolisthesis of axis) Usually neurologically intact
Clay-Shoveler Fracture	Avulsion of spinous process, usually C6 or C7

Imaging

- AP spine x-ray (open-mouth and lateral view), CT

Treatment

- immobilization in cervical collar or halo vest until healing occurs (usually 2-3 mo)
- Type II and III odontoid fractures
- consider surgical fixation for comminution, displacement, or inability to maintain alignment with external immobilization
- confirm stability after recovery with flexion-extension x-rays

Neurologically Determined Death

Definition

- irreversible and diffuse brain injury resulting in absence of clinical brain function
- cardiovascular activity may persist for up to 2 wk

Criteria of Diagnosis

- prerequisites: no CNS depressant drugs/neuromuscular blocking agents, no drug intoxication/poisoning, temperature $>32^{\circ}\text{C}$, no electrolyte/acid-base/endocrine disturbance
- absent brainstem reflexes: pupillary light reflex, corneal reflexes, oculocephalic response, caloric responses (e.g. no deviation of eyes to irrigation of each ear with 50 cc of ice water – allow 1 min after injection, 5 min between sides), pharyngeal and tracheal reflexes, cough with tracheal suctioning, absent respiratory drive at $\text{PaCO}_2 >60$ mmHg or >20 mmHg above baseline (apnea test)
- 2 evaluations separated by time, usually performed by two specialists (e.g. anesthetist, neurologist, neurosurgeon)
- confirmatory testing: flat EEG, absent perfusion assessed with cerebral angiogram

Coma

Definition

- an unrousable state in which patients show no meaningful response to environmental stimuli

Pathophysiology

- lesions affecting the cerebral cortex bilaterally, the reticular activating system (RAS) or their connecting fibres
- focal supratentorial lesions do not alter consciousness except by herniation (compression on the brainstem or on the contralateral hemisphere) or by precipitating seizures

Classification

- structural lesions (tumour, pus, blood, infarction, CSF): 1/3 of comas
 - supratentorial mass lesion: leads to herniation
 - infratentorial lesion: compression of or direct damage to the RAS or its projections
- metabolic disorders/diffuse hemispheric damage: 2/3 of comas
 - deficiency of essential substrates (e.g. oxygen, glucose, vitamin B12)
 - exogenous toxins (e.g. drugs, heavy metals, solvents)
 - endogenous toxins/systemic metabolic diseases (e.g. uremia, hepatic encephalopathy, electrolyte imbalances, thyroid storm)
 - infections (meningitis, encephalitis)
 - trauma (concussion, diffuse shear axonal damage)

Figure 28. Odontoid fracture classification

TLICS Scoring

Parameter	Points
Morphology	
Compression fracture	1
Burst fracture	2
Translational/rotational fracture	3
Distraction	4
Neurologic Status	
Intact	0
Nerve root injury	2
Spinal Cord Status	
Incomplete	3
Complete	2
Cauda equine	3
Posterior Ligamentous Complex	
Intact	0
Injury suspected/indeterminate	2
Injured	3

• TLICS scoring based on morphology of injury, status of posterior ligamentous complex, and neurological status

• Non-operative management if TLICS = 0-3, operative management if TLICS = 5+, either operative or non-operative if TLICS = 4

Investigations and Management

- ABCs
- labs: electrolytes, extended electrolytes, TSH, LFTs, Cr, BUN, toxin screen, glucose
- CT/MRI, LP, EEG

Persistent Vegetative State

Definition

- a condition of complete unawareness of the self and the environment accompanied by sleep-wake cycles with either complete or partial preservation of hypothalamic and brainstem autonomic function
- “awake but not aware”
- follows comatose state

Etiology/Prognosis

- most commonly caused by cardiac arrest or head injury
- due to irreversible loss of cerebral cortical function but intact brainstem function
- average life expectancy is 2-5 yr

Pediatric Neurosurgery

Spinal Dysraphism

- spinal dysraphism refers to a spectrum of congenital anomalies resulting in a defective neural arch through which CNS elements are herniated
- the spectrum is divided largely into aperta (visible lesion; no skin covering) and occulta (no visible lesion; skin covering)

Table 22. Summary of Spinal Dysraphic Anomalies

	SPINA BIFIDA OCCULTA	MENINGOCELE (SPINA BIFIDA APERTA)	MYELOMENINGOCELE (SPINA BIFIDA APERTA)
Definition	Congenital absence of a spinous process and a variable amount of lamina No visible exposure of meninges or neural tissue	Herniation of meningeal tissue and CSF through a defect in the spine, without associated herniation of neural tissue	Herniation of meningeal and CNS tissue through a defect in the spine
Epidemiology	15-20% of the general population; most common at L5 or S1	0.1-0.2% of live births	0.1-0.2% of live births
Etiology		Failure of fusion of posterior neural arch	Primary failure of neural tube closure
Clinical Features	No obvious clinical signs Presence of lumbosacral cutaneous abnormalities (dimple, sinus, port-wine stain, or hair tuft) should increase suspicion of an underlying anomaly (lipoma, dermoid, diastematomyelia)	Most common in lumbosacral area Usually no disability, low incidence of associated anomalies, and hydrocephalus	Sensory and motor changes distal to anatomic level producing varying degrees of weakness Urinary and fecal incontinence Hydrocephalus (65-85% of patients) Most have Type II Chiari malformation (see <i>Chiari Malformations, NS38</i>)
Investigations	Plain film: absence of the spinous process and minor amounts of the neural arch U/S, MRI to exclude spinal anomalies	Plain films, CT, MRI, U/S, echo, GU investigations	Plain films, CT, MRI, U/S, echo, GU investigations
Treatment	Requires no treatment	Surgical excision and tissue repair	Surgical closure to preserve neurologic status and prevent CNS infections Closure <i>in utero</i> shown to decrease hydrocephalus and improve post natal motor scores
Prognosis	Generally good prognosis	Good prognosis with surgical treatment	Operative mortality close to 0%, 95% 2-yr survival 80% have IQ > 80 (but most are 80-95), 40-85% ambulatory, 3-10% have normal urinary continence Early mortality: usually due to Chiari malformation complications (respiratory arrest, aspiration), late mortality: due to shunt malfunction

Figure 29. Spina bifida Occulta, Meningocele, Myelomeningocele

Intraventricular Hemorrhage

- see [Pediatrics, P63](#)

Hydrocephalus in Pediatrics

Etiology

- congenital
 - aqueductal anomalies, primary aqueductal stenosis in infancy
 - secondary gliosis due to intrauterine viral infections (mumps, varicella, TORCH)
 - Dandy-Walker malformation (2-4%)
 - Chiari malformation, especially Type II
 - myelomeningocele
- acquired
 - post meningitis
 - post hemorrhage (SAH, IVH)
 - masses (vascular malformation, neoplastic)

Clinical Features

- symptoms and signs of hydrocephalus are age related in pediatrics
- increased head circumference (HC), bulging anterior fontanelle, widened cranial sutures
- irritability, lethargy, poor feeding, and vomiting
- “cracked pot” sound on cranial percussion
- scalp vein dilation (increased collateral venous drainage)
- sunset sign – forced downward deviation of eyes
- episodic bradycardia and apnea

Investigations

- skull x-ray, U/S, CT, MRI, ICP monitoring

Treatment

- similar to adults ([see Hydrocephalus Treatment, NS9](#))

Dandy-Walker Malformation

Definition

- atresia of foramina of Magendie and Luschka, resulting in:
 - complete or incomplete agenesis of the cerebellar vermis with widely separated, hypoplastic cerebellar hemispheres
 - can be detected *in utero*
 - posterior fossa cyst, enlarged posterior fossa
 - dilatation of 4th ventricle (also 3rd and lateral ventricles)
- associated anomalies
 - hydrocephalus (90%)
 - agenesis of corpus callosum (17%)
 - occipital encephalocele (7%)

Epidemiology

- 2-4% of pediatric hydrocephalus

Clinical Features

- 20% are asymptomatic, seizures occur in 15%
- symptoms and signs of hydrocephalus combined with a prominent occiput in infancy
- ataxia, spasticity, poor fine motor control common in childhood

Investigations

- ultrasound, CT, MRI

Treatment

- asymptomatic patients require no treatment
- associated hydrocephalus requires surgical treatment
- e.g. ventriculoperitoneal (VP) shunt, cystoperitoneal (CP) shunt, lumboperitoneal (LP) shunt, ventriculoatrial (VA) shunt, lumbar drain

Prognosis

- 75-100% survival, 50% have normal IQ

Chiari Malformations

Definition

- malformations at the medullary-spinal junction

Etiology

- unclear, likely maldevelopment/dysgenesis during fetal life

Categories

Table 23. Categories of Chiari Malformations

	Type I	Type II
Definition	Cerebellar tonsils lie below the level of the foramen magnum	Part of cerebellar vermis, medulla, and 4th ventricle extend through the foramen magnum often to midcervical region
Epidemiology	Average age at presentation 15 yr	Present in infancy
Clinical Features	Many are asymptomatic Pain (69%), weakness (56%), numbness (52%), loss of temperature sensation (40%) Central cord syndrome (65%) Foramen magnum compression syndrome (22%), Cerebellar syndrome (11%), Syringomyelia (50%), Hydrocephalus (10%)	Findings due to brainstem and lower cranial nerve dysfunction Neurogenic dysphagia (69%), apnea (58%), stridor (56%), aspiration (40%), arm weakness (27%), downbeat nystagmus Respiratory arrest is the most common cause of mortality Usually associated with myelomeningocele and hydrocephalus
Investigations	MRI	MRI
Treatment	Symptomatic patients (early surgery recommended; <2 yr post symptom onset) → suboccipital craniectomy, duraplasty	Preserved When symptomatic, check the shunt first. Then consider surgical decompression (which does not reverse intrinsic brainstem abnormalities) → cervical laminectomy, duraplasty

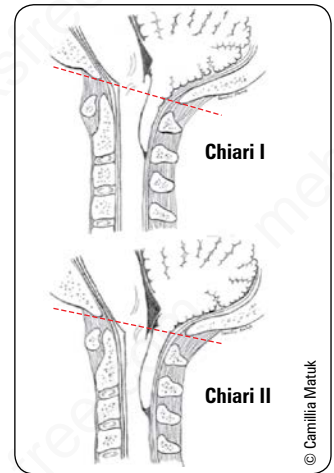

Figure 30. Chiari malformations

© Camilla Maruk

Craniosynostosis

Definition

- premature closure of the cranial suture(s)

Classification

- sagittal (most common): long narrow head with ridging sagittal suture (scaphocephaly)
- coronal: expansion in superior and lateral direction (brachiocephaly)
- metopic (trigonocephaly)
- lambdoid: least common

Epidemiology

- 0.6/1,000 live births, most cases are sporadic; familial incidence is 2% of sagittal and 8% of coronal synostosis

Clinical Features

- skull deformity, raised ICP ± hydrocephalus
- ophthalmologic problems due to increased ICP or bony abnormalities of the orbit
- must differentiate between positional plagiocephaly (secondary to back sleeping)

Investigations

- plain radiographs, CT scan

Treatment

- parental counselling about nature of deformity, associated neurological symptoms
- surgery for cosmetic purposes, except in cases of elevated ICP (≥2 sutures involved)

Pediatric Brain Tumours

• see *Tumours, NS11*

Epidemiology

- 20% of all pediatric cancers (second only to leukemia)
- 60% of pediatric brain tumours are infratentorial
- pediatric brain tumours arise from various cellular lineages
 - glia: low-grade astrocytoma (supra- or infratentorial), anaplastic astrocytoma, glioblastoma multiforme (largely supratentorial) (see Astrocytoma, NS12)
 - primitive nerve cells: supratentorial PNET
 - 90% of neonatal brain tumours, infratentorial (medulloblastoma), pineal gland (pineoblastoma)
 - non-neuronal cells: germ cell tumour, craniopharyngioma, dermoid, meningioma, neurinoma (schwannoma), pituitary adenoma, others

Most Common Pediatric Brain Tumours
 Astrocytoma, low grade
 Supratentorial
 Infratentorial
 Medulloblastoma
 Ependymoma
 Glioblastoma

Clinical Features

- vomiting, seizure, macrocrania, hydrocephalus
- developmental delay, poor feeding, failure to thrive
- often initially escapes diagnosis due to expansile cranium and neural plasticity in children

Table 24. Overview of Childhood Primary Brain Tumours*

Pilocytic (low grade) Astrocytoma	Usually in posterior fossa Well circumscribed Benign, good prognosis
Medulloblastoma	A primitive neuroectodermal tumour (PNET) In cerebellum → compresses 4th ventricle → hydrocephalus Highly malignant
Ependymoma	In 4th ventricle → hydrocephalus Poor prognosis
Hemangioblastoma	Often cerebellar Associated with von Hippel-Lindau syndrome with retinal angiomas Can produce EPO → secondary polycythemia
Craniopharyngioma	Causes bitemporal hemianopsia (thus often confused with pituitary adenoma) Most common supratentorial childhood tumour Benign

Functional Neurosurgery

Movement Disorders

• see *Neurology, Tremor, N31, Parkinson's Disease, N32, Dystonia, N33, and Multiple Sclerosis, N52*

Table 25. Surgical Targets for Movement Disorders

Disorder	Indications	Procedures	Outcomes	Morbidity
Parkinson's Disease	Intractable contralateral bradykinesia/tremor Failure of medical management (advanced disease) Drug-induced dyskinesias (see dystonia, below)	Simultaneous, bilateral surgery/stimulation is most common Preferred target: anterodorsal subthalamic nucleus (STN) Other targets: stereotactic ablation (pallidotomy)/stimulation of posteroventral globus pallidus pars interna (GPI) Caudal zona incerta Parkinsonian tremor: stereotactic ablation (thalamotomy)/stimulation of ventral intermediate (Vim) nucleus of thalamus	39-48% improvement in Unified Parkinson's Disease Rating Scale (UPDRS) scores Reduced dosage of medications (STN) More effective than medical management in advanced PD Early intervention may reduce severity, course, and progression of disease Of little benefit for patients with atypical presentations	Intracerebral hemorrhage, infection, seizure (1%-4%) Paresthesias Involuntary movements Cognitive functioning: decreased lexical fluency, impaired executive function (STN > GPI) Psychiatric: depression, mania, anxiety, apathy (STN > GPI)
Dystonia	Contralateral primary (generalized) dystonias; cervical and tardive dystonias (GPI) Contralateral secondary dyskinesia (i.e. drug-induced: L-dopa, neuroleptics; STN)	Preferred target (primary dystonia): stereotactic ablation (pallidotomy)/stimulation of posteroventral GPI Secondary dystonia: stimulation of anterodorsal STN Stimulation of ventral posterior lateral (VPL) thalamic nucleus	Primary dystonia: 51% reduction in Burke-Fahn-Marsden Dystonia Scale (BFMDS) score Secondary dystonia: 62-89% improvement in dystonias Delayed effects: weeks to months	Intracerebral hemorrhage, infection, seizure (1%-4%) Minor effects on cognitive functioning (especially decreased lexical fluency; STN > GPI)
Tremor	Contralateral appendicular ET (first disorder to be treated by DBS; DBS is viable alternative to Rx) Intention tremor (IT) resulting from demyelination of cerebellar outflow tracts (e.g. in multiple sclerosis) Brainstem tremor (Holmes tremor)	Preferred target: stereotactic ablation (thalamotomy)/stimulation of Vim nucleus of thalamus Other targets: stimulation of caudal zona incerta Parkinsonian tremor: stimulation of anterodorsal STN	Durable reductions in essential tremor rating scale (ETRS) scores Reduced dosage of medications Conflicting data on vocal/facial tremor	Intracerebral hemorrhage, infection, seizure (1%-4%) Paresthesias/pain Dysarthria Ataxia Minor effects on cognitive functioning (especially decreased lexical fluency) Tolerance may develop over time

Neuropsychiatric Disorders

- see [Neurology, N20](#) and [Psychiatry](#) for *Tourette's Syndrome, Obsessive Compulsive Disorder and Depression*

Table 26. Surgical Targets for Neuropsychiatric Disorders

Disorder	Indications	Procedures	Outcomes	Morbidity
Obsessive Compulsive Disorder (OCD)	Severe symptoms refractory to medical management	Anterior capsulotomy/stimulation of the anterior limb of the internal capsule (IC)	Currently under investigation Reportedly 25-75% response rate	Intracerebral hemorrhages (1-2%) Mild effects on cognitive functioning Anxiety ± panic disorder (case report)
Tourette's Syndrome	Severe symptoms refractory to medical management	Stimulation of midline intralaminar nuclei of the thalamus Stimulation of motor and limbic portions of GPI Stimulation of the anterior limb of the IC	Currently under investigation Reportedly >70% reduction in vocal or motor tics + urge	Intracerebral hemorrhages (1-2%) Mild sexual dysfunction
Major Depressive Disorder (MDD)	Severe depression refractory to medical management and ECT	Stimulation of the subgenual cingulate cortex	Currently under investigation Reportedly 60% response rate; 35% remission rate	Intracerebral hemorrhages (1-2%) Pain, H/A Worsening mood, irritability

Chronic Pain

Table 27. Surgical Targets for Chronic Pain

Disorder	Indications	Procedures	Outcomes	Morbidity
Neuropathic Pain	Severe, intractable, organic neuropathic pain (e.g. post-stroke pain, phantom limb pain, trigeminal neuralgia, chronic low-back pain, post-operative neuropathic pain) complex regional pain syndrome)	Preferred target: stimulation of the contralateral VPL VPM thalamic nuclei ± periventricular/periaqueductal grey matter (PVG/PAG) Other targets: stimulation of the contralateral IC Stimulation of the contralateral motor cortex For post-operative neuropathic pain, surgical procedure may be aimed at correcting any identifiable residual deformity from prior spine surgery. Surgery is not primary modality if no structurally correctable radiologic findings	47% improvement in perception of pain intensity Less favourable results in central pain syndromes and poorly localized pain	Intracerebral hemorrhages (1-2%) Paresthesia Anxiety ± panic disorder
Nociceptive Pain	Severe, intractable, organic nociceptive pain	Bilateral (most common) stimulation of the PVG/PAG	Reportedly 63% improvement in perception of pain intensity	Intracerebral hemorrhages (1-2%) Paresthesia Anxiety ± panic disorder

Surgical Management of Epilepsy

- see [Neurology, N19](#) for the medical treatment of epilepsy

Indications

- medically refractory seizures, usually defined as seizures resistant to two first line anti-seizure medications used in succession
- identification of a distinct epileptogenic region through clinical history, EEG, MRI, and neuropsychological testing; other localizing investigations include magnetoencephalography, SPECT, and PET
- if a distinct epileptogenic region cannot be identified, the patient may be a candidate for a palliative procedure such as corpus callosotomy

Procedure

- adults: resection of the hippocampus and parahippocampal gyrus for mesial temporal lobe epilepsy arising from mesial temporal sclerosis
- children: resection of an epileptogenic space-occupying lesion
- hemispherectomy and corpus callosotomy are less common

Outcomes

- 41-79% of adult patients are seizure free for 5 yr after temporal lobe resection
- 58-78% of children are seizure free after surgery
- surgery is associated with improvements in preexisting psychiatric conditions such as depression and anxiety, as well as improvement in quality of life measures

Morbidity

- 0.4-4% of surgical patients will have partial hemianopsia, aphasia, motor deficit, sensory deficit, or cranial nerve palsy following anteromedial temporal lobectomies
- most patients will have some decline in verbal memory following dominant temporal lobectomy and in visuospatial memory in non-dominant temporal resection
- the degree of memory decline stabilizes after 1-2 yr

Predictors

- positive predictive factors for seizure freedom following anteromedial temporal lobectomy
 - hippocampal sclerosis (unilateral)
 - focal localization of interictal epileptiform discharges
 - absence of pre-operative generalized seizures
 - tumoural cause
 - complete resection of the lesion

Surgical Management for Trigeminal Neuralgia

- reserved for cases refractory to medical management; see [Neurology, N42](#) for medical management

Surgical Options

- trigeminal nerve branch procedures
 - local blocks (phenol, alcohol)
 - neurectomy of the trigeminal branch
 - nerve branches
 - V1 block at the supraorbital, supratrochlear nerves
 - V2 block at the foramen rotundum or infraorbital nerves
 - V3 block at the foramen ovale
- percutaneous trigeminal rhizotomy
 - glycerol injection
 - mechanotrauma via catheter balloon
- radiofrequency thermocoagulation
- Gamma Knife® radiosurgery
- microvascular decompression
 - posterior fossa craniotomy with microsurgical exploration of the root entry zone, displacement of the vessel impinging on the nerve with placement of non-absorbable Teflon® felt

Basic Anatomy Review

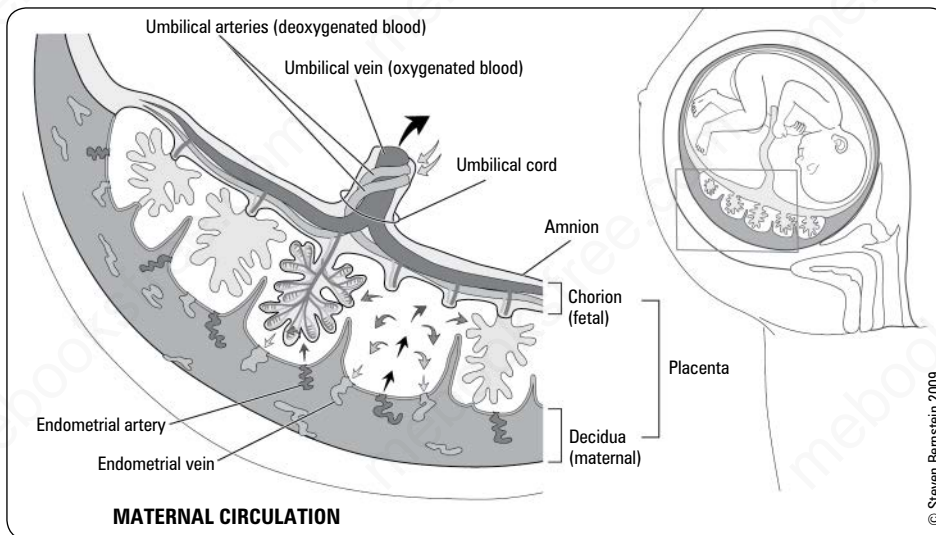

Figure 1. Placental blood flow

Placenta

- site of fetal nutritive, respiratory, and excretory function
- discoid mass composed of fetal (chorion frondosum) and maternal (decidua basalis) tissues divided by fissures into cotyledons (lobules) on the uterine side
- produces hormones such as progesterone, placental lactogen, estrogen, relaxin, β -hCG, and IGFs
- poor implantation can lead to spontaneous abortion
- abnormal location, implantation, or detachment can lead to antepartum hemorrhage (*see Obstetrical Hemorrhage, OB13*)

Pregnancy

Diagnosis of Pregnancy

History

- symptoms: amenorrhea, nausea and/or vomiting, breast tenderness, urinary frequency, and fatigue
- obstetrical and gynecological history
- obtain the year, location, mode of delivery, duration of labour, sex, gestational age, birth weight, and complications of every pregnancy; organize into GTPAL format
 - Gravidity (G)
 - ♦ G: total number of pregnancies of any gestation (multiple gestation=one pregnancy)
 - ♦ includes current pregnancy, abortions, ectopic pregnancies, and hydatidiform moles

- Parity (TPAL)
 - ♦ T: number of term infants delivered (>37 wk)
 - ♦ P: number of premature infants delivered (20-36+6 wk)
 - ♦ A: number of abortions (loss of intrauterine pregnancy prior to viability of fetus <20 wk and/or <500 g fetal weight)
 - induced (therapeutic) and spontaneous (miscarriage)
 - ♦ L: number of living children

Physical Signs

- Goodell's sign: softening of the cervix (4-6 wk)
- Chadwick's sign: bluish discoloration of the cervix and vagina due to pelvic vasculature engorgement (6 wk)
- Hegar's sign: softening of the cervical isthmus (6-8 wk)
- uterine enlargement
- breast engorgement, areolae darkening, and prominent vascular patterns

Investigations

- β -hCG: peptide hormone composed of α and β subunits produced by placental trophoblastic cells – maintains the corpus luteum during pregnancy
 - positive in serum 9 d post-conception, positive in urine 28 d after first day of LMP
 - plasma levels usually double every 1.4-2.0 d, peak at 8-10 wk, then fall to a plateau until delivery
 - ♦ levels less than expected suggest: ectopic pregnancy, abortion, inaccurate dates, and some normal pregnancies
 - ♦ levels greater than expected suggest: multiple gestation, molar pregnancy, Trisomy 21, or inaccurate dates
- U/S:
 - transvaginal
 - ♦ 5 wk amenorrhea: gestational sac visible
 - ♦ 6 wk: fetal pole visible
 - ♦ 7-8 wk: fetal heart activity visible
 - transabdominal
 - ♦ 6-8 wk: intrauterine pregnancy visible

β -hCG Rule of 10s

10 IU at time of missed menses
100,000 IU at 10 wk (peak)
10,000 IU at term

Trimesters

- T1 (first trimester): 1-14 wk
- T2 (second trimester): 14-28 wk
- T3 (third trimester): 28-42 wk
- Normal pregnancy term: 37-42 wk

Maternal Physiologic Adaptations to Pregnancy

Table 1. Physiologic Changes During Pregnancy

Skin	Increased pigmentation of perineum and areola, chloasma (pigmentation changes under eyes and on bridge of nose), linea nigra (midline abdominal pigmentation), spider angiomas, palmar erythema due to increased estrogen, striae gravidarum due to connective tissue changes
Cardiovascular	Hyper-dynamic circulation Increased CO, H, and blood volume Decreased blood pressure: decreased PVR and decreased venous return from enlarging uterus compressing IVC and pelvic veins Increased venous pressure leads to risk of varicose veins, hemorrhoids, leg edema
Hematologic	Hemodilution causes physiologic anemia and apparent decrease in hemoglobin and hematocrit Increased leukocyte count but impaired function leads to improvement in autoimmune diseases Gestational thrombocytopenia: mild (platelets >70,000/ μ L) and asymptomatic, normalizes within 2-12 wk following delivery Hypercoagulable state: increased risk of DVT and PE but also decreased bleeding at delivery
Respiratory	Increased incidence of nasal congestion Increased O ₂ consumption to meet increased metabolic requirements Elevated diaphragm (i.e. patient appears more "barrel-chested") Increased minute ventilation leads to decreased CO ₂ ; resulting in mild respiratory alkalosis that helps CO ₂ diffuse across the placenta from fetal to maternal circulation Decreased TLC, FRC, and RV No change in VC and FEV ₁
Gastrointestinal	GERD due to increased intra-abdominal pressure and progesterone (causing decreased sphincter tone and delayed gastric emptying) Increased gallstones due to progesterone causing increased gallbladder stasis Constipation due to progesterone causing decreased GI motility and hemorrhoids as a result of constipation and increased intra-abdominal pressure
Genitourinary	Increased urinary frequency due to increased total urinary output Increased incidence of UTI and pyelonephritis due to urinary stasis (see <i>Urinary Tract Infection, OB28</i>) Glycosuria that can be physiologic especially in the 3rd trimester; consider testing for GDM if noted in first 2 trimesters Ureters and renal pelvis dilation (R>L) due to progesterone-induced smooth muscle relaxation and uterine enlargement Increased CO and thus increased GFR leads to decreased creatinine (normal in pregnancy 35-44 mmol/L), uric acid, and BUN
Neurologic	Increased incidence of carpal tunnel syndrome and Bell's palsy
Endocrine	Thyroid: moderate enlargement (not clinically detectable) and increased basal metabolic rate Increased total thyroxine and thyroxine binding globulin (TBG) Free thyroxine index and TSH levels are normal Adrenal: maternal cortisol rises throughout pregnancy (total and free) Calcium: decreased total maternal Ca ²⁺ due to decreased albumin Free ionized Ca ²⁺ (i.e. active) proportion remains the same due to parathyroid hormone (PTH), results in increased bone resorption and gut absorption, increased bone turnover (but no loss of bone density due to estrogen inhibition)

Antepartum Care

- can be provided by obstetrician, family physician, midwife, or multidisciplinary team (based on patient preference and risk factors)

Family doctors and midwives to consider OB consultation if:

- Insulin-dependent GDM
- VBAC
- HTN
- Multiple gestation
- Malpresentation
- Active antepartum hemorrhage
- PTL/PPROM
- Failure to progress/descend
- Induction/augmentation if high risk
- Tears: 3rd or 4th degree
- Retained placenta

Note: Guidelines vary by institution and by provincial midwifery colleges

Advise all women capable of becoming pregnant to supplement their diet with 0.4 mg/d of folic acid (CTFPHC Grade II-2-A Evidence)

Prenatal and genetic screening are voluntary and require proper counselling and informed consent before proceeding
HIV is done automatically in some provinces as opt-out testing; need to inform patient of this

In history of previous pregnancies, **ALWAYS**

ask:
GTPAL
Year
Sex
Weight
Gestational age (GA)
Mode of delivery
Length of labour
Complications

Ask every woman about abuse – not just those whose situations raise suspicion of abuse **AND** ask as early as possible in pregnancy

Preconception Counselling

- 3-8 wk GA is a critical period of organogenesis, so early preparation is vital
- **past medical history:** optimize illnesses and medications prior to pregnancy (see *Medical Complications of Pregnancy, OB25, and Medications, OB10*)
- **supplementation**
 - folic acid: encourage diet rich in folic acid and supplementation 8-12 wks pre-conception until end of T1 to prevent NTDs
 - ♦ 0.4-1 mg daily in all women; 5 mg if previous NTD, antiepileptic medications, DM, or BMI >35 kg/m²
- iron supplementation, prenatal vitamins
- **risk modification**
 - lifestyle: balanced nutrition and physical fitness
 - medications: discuss teratogenicity of medications so they may be adjusted or stopped if necessary
 - infection screening: rubella, HBsAg, VDRL, Pap smear, gonorrhea/chlamydia, HIV, TB testing based on travel and health care worker, history of varicella or vaccination, parvovirus immunity if exposed to small children, cytomegalovirus immunity if health care worker, toxoplasmosis serology if cats or gardening, last pertussis vaccine
 - genetic testing as appropriate for high risk groups (see *Prenatal Screening, Table 2*); consider genetics referral in known carriers, recurrent pregnancy loss/stillbirth, family members with developmental delay, birth anomalies, genetic diseases, consanguinity
 - social: smoking, alcohol, drug use, domestic violence (see *Family Medicine, FM11, FM12, FM26*)

Initial Prenatal Visit

- usually within 8-12 wk of the first day of LMP or earlier if <20 or >35 yr old, bleeding, very nauseous, or other risk factors present

History

- gestational age by dates from the first day of the LMP
 - Naegle's rule: 1st day of LMP + 1 year + 7 days – 3 months
 - e.g. LMP = 1 Apr 2014, EDC = 8 Jan 2015 (modify if cycle >28 d by adding number of d >28)
- if LMP unreliable, get a dating ultrasound which could coincide with nuchal translucency at ~12 wk
- dates should change if T1 U/S is greater than 5 days in difference from LMP due date
- history of present pregnancy (e.g. bleeding, N/V) and all previous pregnancies
- past medical, surgical, and gynecological history
- prescription and non-prescription medications
- family history: genetic diseases, birth defects, multiple gestation, consanguinity
- social history: smoking, alcohol, drug use, domestic violence (see *Family Medicine, FM11, FM12, FM26*)

Physical Exam

- complete physical exam to obtain baseline patient information – BP and weight important for interpreting subsequent changes

Investigations

- blood work
 - CBC, blood group and Rh status, antibody screen, infection screening as per preconception counselling
- urine R&M, midstream urine C&S
 - screen for bacteriuria and proteinuria
- pelvic exam
 - pap smear (only if required according to patient history and provincial screening guidelines), cervical or urine PCR for *N. gonorrhoeae* (GC) and *C. trachomatis*

Nausea and Vomiting

Epidemiology

- affects 50-90% of pregnant women
- often limited to T1 but may persist beyond this

Management

- rule out other causes of N/V
- weigh frequently, assess level of hydration, test urine for ketones
- **non-pharmacological**
 - avoid mixing fluids and solids, frequent small meals (bland, dry, salty are better tolerated)
 - electrolyte oral solutions (Pedialyte®, Gatorade®)
 - stop prenatal vitamins
 - increase sleep/rest
 - ginger (maximum 1,000 mg/d)
 - acupuncture, acupressure
- **pharmacological**
 - first line: Diclectin® (10 mg doxylamine succinate with vitamin B6) 4 tablets PO daily (1 q am, 1 q lunch and 2 qhs) up to maximum of 8 tablets/day
 - if no improvement, try dimenhydrinate (50-100 mg q4-6h PO), followed by hydroxyzine, pyridoxine, phenothiazine, or metoclopramide
 - vitamin B6 lollipops
 - if patient dehydrated, assess fluid replacement needs and resuscitate accordingly
- **severe/refractory**
 - consider homecare with IV fluids and parenteral anti-emetics, hospitalization

Hyperemesis Gravidarum

Definition

- intractable N/V, usually presents in T1 then diminishes; occasionally persists throughout pregnancy
- affects ~1% of pregnancies

Etiology

- multifactorial with hormonal, immunologic, and psychological components
- rapidly rising β -hCG \pm estrogen levels may be implicated

Investigations

- rule out systemic causes: GI inflammation, pyelonephritis, thyrotoxicosis
- rule out other obstetrical causes: multiple gestation, GTN, HELLP syndrome
- CBC, electrolytes, BUN, creatinine, LFTs, urinalysis
- ultrasound

Management

- thiamine supplementation may be indicated
- non-pharmacological (*see Nausea and Vomiting*)
- pharmacological options
 - Diclectin® (for dosage, *see Nausea and Vomiting*)
 - Dimenhydrinate can be safely used as an adjunct to Diclectin® (1 suppository bid or 25 mg PO qid)
 - other adjuncts: hydroxyzine, pyridoxine, phenothiazine, metoclopramide
 - also consider: ondansetron or methylprednisolone
 - if severe: admit to hospital, NPO initially then small frequent meals; correct hypovolemia, electrolyte disturbance, and ketosis; TPN (if very severe) to reverse catabolic state

Complications

- maternal
 - dehydration, electrolyte and acid-base disturbances
 - Mallory-Weiss tear
 - Wernicke's encephalopathy, if protracted course
 - death
- fetal: usually none, IUGR is 15x more common in women losing >5% of pre-pregnancy weight

Subsequent Prenatal Visits

Timing

- for uncomplicated pregnancies, SOGC recommends q4-6 wk until 30 wk, q2-3 wk from 30 wk, and q1-2 wk from 36 wk until delivery

Assess at Every Visit

- estimated GA
- history: fetal movements, uterine bleeding, leaking, cramping, questions, concerns
- physical exam: BP, weight gain, SFH, Leopold's maneuvers (T3) for lie, position, and presentation of fetus
- investigations: urinalysis for glucosuria and proteinuria in high risk women; fetal heart rate starting at 10-12 wk using Doppler U/S

Symphysis Fundal Height

SFH < Dates

- Date miscalculation
- IUGR
- Fetal demise
- Oligohydramnios
- Early engagement

SFH > Dates

- Date miscalculation
- Multiple gestation
- Polyhydramnios
- LGA (familial, DM)
- Fibroids

Leopold's Maneuvers

- performed after 30-32 wk gestation
- first maneuver: to determine which fetal part is lying furthest away from the pelvic inlet
- second maneuver: to determine the location of the fetal back
- third maneuver: to determine which fetal part is lying above the pelvic inlet
- fourth maneuver: to locate the fetal brow

Figure 2. Leopold's maneuvers (T3)

Reprinted with permission from Essentials of Clinical Examination Handbook, 6th ed. Lincoln, McSheffrey, Tran, Wong

Prenatal Screening and Diagnostic Tests

Screening Tests

- testing should only occur following counselling and with informed consent from the patient

Table 2. High-Risk Population Screening Tests

Disease (Inheritance)	Population(s) at Risk	Screening Test(s)
Thalassemia (AR)	Mediterranean, South East Asian, Western Pacific, African, Middle Eastern, Caribbean, South American	CBC (MCV and MCH), Hb electrophoresis, or HPLC
Sickle Cell (AR)	African, Caribbean, Mediterranean, Middle Eastern, Indian, South American	CBC (MCV and MCH), Hb electrophoresis, or HPLC
Cystic Fibrosis (CF) (AR)	Family history of CF in patient or partner or medical condition linked to CF like male infertility	CFTR gene DNA analysis
Tay Sachs Disease (AR)	Ashkenazi Jewish*, French Canadians, Cajun	Enzyme assay HEXA, or DNA analysis HEXA gene
Fragile X Syndrome (X-linked)	Family history – confirmed or suspected	DNA analysis: FMR-1 gene

AR = autosomal recessive; HEXA = hexosaminidase A; HPLC = high performance liquid chromatography

*If both partners are Ashkenazi Jewish, test for Canavan disease and Familial Dysautonomia (FD); if family history of a specific condition, look for carrier status: e.g. Gaucher, CF, Bloom syndrome, Niemann-Pick disease, etc. In all cases, if both partners are positive, refer for genetic counselling.

Table 3. Gestation-Dependent Screening Investigations

Gestational Age (wk)	Investigations	Details
8-12	Dating U/S, possible Pap smear, chlamydia/gonorrhea testing, urine C&S, HIV, VDRL, HepBSAg, Rubella IgG, Parvovirus IgM or IgG if high risk (small child at home or daycare worker/primary teacher), Varicella IgG if no history of disease/immunization, CBC, blood group and screen, urine cultures to detect asymptomatic bacteriuria	
>10	NIPT	Measures cell free fetal DNA in maternal circulation
10-12	CVS	
11-14	Enhanced FTS IPS Part 1	Measures 1. Nuchal translucency on U/S 2. β -hCG 3. PAPP-A 4. PIGF (enhanced FTS only) 5. AFP (enhanced FTS only)
11-14	Nuchal translucency U/S	
15-16 to term	Amniocentesis	
15-20	IPS Part 2	Measures 1. MSAFP 2. β -hCG 3. Unconjugated estrogen (estriol or μ E3) 4. Inhibin A

Routine T2 U/S at 18-22 wk Helps Determine

- Number of fetuses
- GA (if no prior U/S)
- Location of placenta
- Fetal anomalies

Table 3. Gestation-Dependent Screening Investigations (continued)

Gestational Age (wk)	Investigations	Details
15-20	MSS	Measures 1. MSAFP 2. β -hCG 3. Unconjugated estrogen (estriol or μ E3) 4. Inhibin A
18-20 to term	Fetal movements (quickening)	
18-20	U/S for dates, fetal growth, and anatomy assessment	
24-28	Gestational Diabetes Screen 50 g OGCT	See <i>Diabetes Mellitus</i> , OB26
28	Repeat CBC RhIG for all Rh negative women	
35-37	GBS screen	See <i>Group B Streptococcus</i> , OB27
6 wk postpartum	Discuss contraception, menses, breastfeeding, depression, mental health, support Physical exam: breast exam, pelvic exam including Pap smear (only if due as per provincial screening)	

Maternal serum screen is also referred to as Triple Screen; if Inhibin A is also tested, it is referred to as Quadruple Screen

ULTRASOUND SCREENING

- 8-12 wk GA: dating ultrasound (most accurate form of pregnancy dating)
- measurement of crown-rump length (margin of error: \pm 5 d)
- change EDC to U/S date if $>$ 5 d discrepancy from EDC based on LMP
- 11-14 wk GA: NTUS
- measures the amount of fluid behind the neck of the fetus
- early screen for Trisomy 21 (may also detect cardiac and other aneuploidies like Turner's syndrome)
- NT measurement is necessary for the FTS and IPS Part 1
- 18-20 wk GA: growth and anatomy U/S (margin of error: \pm 10 d)
- earlier or subsequent ultrasounds performed when medically indicated

NON-INVASIVE PRENATAL TESTING (NIPT)

- analyses maternal blood for circulating cell free fetal DNA (ccffDNA) at 10 wk GA onwards. Requires dating ultrasound for accuracy

Advantage

- in high risk women ($>$ age 35) highly sensitive for Trisomy 21 ($>$ 99.5%), specificity ($>$ 99.8%) - can also look for trisomy 18, 13 and some X and Y disorders as well as common microdeletions
- not harmful to the pregnancy, results available in 7-10 day

Disadvantages

- does not screen for ONTD
- high cost to patient (only covered in some provinces in certain cases)
- unclear how accurate yet in low risk women ($<$ 35)
- need to confirm with invasive testing
- does not test for all aneuploidy

Table 4. Comparison of FTS, MSS, and IPS

FTS	MSS	IPS
11-14 wk	15-20 wk	11-13 wk U/S-Nuchal Translucency 11-14 wk: FTS blood 15-20 wk : MSS blood including inhibin
<p>Risk estimate for</p> <ol style="list-style-type: none"> Down syndrome (Trisomy 21): increased NT, increased β-hCG, decreased PAPP-A Trisomy 18 : increased NT, decreased PAPP-A, decreased β-hCG <p>Note: does not measure risk of open neural tube defect (ONTD) and should be combined with MSAFP at 15-20 wk Useful where patient wants results within the first trimester More accurate estimate of Down syndrome risk than MSS, sensitivity \sim85% (when combined with age) 5% false positive rate Patients with positive screen should be offered CVS, amniocentesis, or NIPT (covered in some provinces, self-pay in others)</p>	<p>Risk estimate for</p> <ol style="list-style-type: none"> ONTD: increased MSAFP (sensitivity 80-90%) Trisomy 21: decreased MSAFP, increased β-hCG, decreased μE3 (sensitivity 65%) Trisomy 18: decreased MSAFP, decreased β-hCG, decreased μE3, decreased inhibin (sensitivity 80%) <p>Only offered alone if patient missed the time window for IPS or FTS 8% baseline false positive rate for Trisomy 21, lower for NTD and Trisomy 18 Patients with positive screen should be offered U/S, amniocentesis, or NIPT (covered in some provinces, self-pay in others)</p>	<p>Risk estimate for ONTD, Trisomy 21, Trisomy 18</p> <p>Sensitivity \sim85-90%</p> <p>2% false positive rate</p> <p>Patients with positive screen should be offered U/S and/or amniocentesis or NIPT (covered in some provinces, self-pay in others)</p>

Note: In twins, FTS, MSS, and IPS are not applicable; screen with NT, NIPT for chromosomal abnormalities and MSAFP for ONTDs

DDx of Increased MSAFP

- Incorrect GA
- $>$ 1 fetus (e.g. twins)
- Fetal demise
- ONTD
- Abdominal wall defects (e.g. omphalocele)

Symphysis Fundal Height (SFH)

- | | |
|-------|---|
| 12 wk | Uterine fundus at pubic symphysis |
| 20 wk | Fundus at umbilicus, SFH should be within 2 cm of GA between 20-36 wk |

Diagnostic Tests

Indications

- age >35 yr (increased risk of chromosomal anomalies)
 - risk factors in current pregnancy
 - abnormal U/S
- abnormal prenatal screen (IPS, FTS, or MSS)
- past history/family history of
 - chromosomal anomaly or genetic disease
 - either parent a known carrier of a genetic disorder or balanced translocation
 - consanguinity
 - >3 spontaneous abortions

AMNIOCENTESIS

- U/S-guided transabdominal extraction of amniotic fluid

Indications

- identification of genetic anomalies (15-16 wk gestation) as per indications above
- confirmation of positive NIPT testing
- positive FTS/IPS
- assessment of fetal lung maturity (T3) via the L/S ratio (lecithin:sphingomyelin)
 - if >2:1, RDS is less likely to occur

Advantages

- also screens for ONTD (acetylcholinesterase and amniotic AFP) – 96% accurate
- in women >35 yr, the risk of chromosomal anomaly (1/180) is greater than the risk of miscarriage from the procedure
- more accurate genetic testing than CVS

Disadvantages

- 1/200 risk of procedure related pregnancy loss, 1/100 for multiple gestations
- results take 14-28 d; QF-PCR or FISH can be done on chromosomes X, Y, 21, 22, 13, 18 to give preliminary results in 48 h

CHORIONIC VILLUS SAMPLING

- biopsy of fetal-derived chorion using a transabdominal needle or transcervical catheter at 10-12 wk

Advantages

- enables pregnancy to be terminated earlier than with amniocentesis
- rapid karyotyping and biochemical assay within 48 h, including FISH analysis
- high sensitivity and specificity

Disadvantages

- 1-2% risk of procedure related pregnancy loss
- does not screen for ONTD
- 1-2% incidence of genetic mosaicism “false negative” results

ISOIMMUNIZATION SCREENING

Definition

- isoimmunization: antibodies (Ab) produced against a specific RBC antigen (Ag) as a result of antigenic stimulation with RBC of another individual

Etiology

- maternal-fetal circulation normally separated by placental barrier, but sensitization can occur and can affect the current pregnancy, or more commonly, future pregnancies
- anti-Rh Ab produced by a sensitized Rh-negative mother can lead to fetal hemolytic anemia
- risk of isoimmunization of an Rh-negative mother with an Rh-positive ABO-compatible infant is 16%
- sensitization routes
- incompatible blood transfusions
- previous fetal-maternal transplacental hemorrhage (e.g. ectopic pregnancy, abruption)
- invasive procedures in pregnancy (e.g. prenatal diagnosis, cerclage, D&C)
- any type of abortion
- labour and delivery

Investigations

- screening with indirect Coombs test at first visit for blood group, Rh status, and antibodies
- Kleihauer-Betke test used to determine extent of fetomaternal hemorrhage by estimating volume of fetal blood volume that entered maternal circulation
- detailed U/S for hydrops fetalis

Compared to CVS, amniocentesis has a higher accuracy of prenatal cytogenetic diagnosis (99.8% vs. 97.5%) and lower risk of spontaneous abortion (0.5% vs. 1-2%)

Risk Factors for Neural Tube Defects

GRIMM

Genetics: family history of NTD (risk of having second child with NTD is increased to 2-5%), consanguinity, chromosomal (characteristic of Trisomy 13, 18, and 21)

Race: European Caucasians > African Americans, 3-fold higher in Hispanics
 Insufficient vitamins: zinc and folate
 Maternal chronic disease (e.g. DM)
 Maternal use of antiepileptic drugs

General population risk for NTD is 0.1%

Rh Antibody Titre

A positive titre ($\geq 1:16$) indicates an increased risk of fetal hemolytic anemia

- MCA dopplers are done to assess degree of fetal anemia; if not available, bilirubin is measured by serial amniocentesis to assess the severity of hemolysis
- cordocentesis for fetal Hb should be used cautiously (not first-line)

Prophylaxis

- exogenous Rh IgG (Rhogam® or WinRho®) binds to Rh antigens of fetal cells and prevents them from contacting maternal immune system
- Rhogam® (300 µg) given to all Rh negative and antibody screen negative women in the following scenarios:
 - routinely at 28 wk GA (provides protection for ~12 wk)
 - within 72 h of the birth of an Rh positive fetus
 - with any invasive procedure in pregnancy (CVS, amniocentesis)
 - in ectopic pregnancy
 - with miscarriage or therapeutic abortion
 - with an antepartum hemorrhage
 - with trauma
- a Kleihauer-Betke test or Flow cytometry can be used to determine whether more than 300 µg of RhIg is required (>30 ml fetal blood)
- if Rh negative and Ab screen positive, follow mother with serial monthly Ab titres throughout pregnancy + ultrasounds ± serial amniocentesis as needed (Rhogam® has no benefit)

Treatment

- falling biliary pigment warrants no intervention (usually indicative of either unaffected or mildly affected fetus)
- intrauterine transfusion of O-negative pRBCs may be required for severely affected fetus or early delivery of the fetus for exchange transfusion

Complications

- anti-Rh IgG can cross the placenta and cause fetal RBC hemolysis resulting in fetal anemia, CHF, edema, ascites
- severe cases can lead to fetal hydrops (edema in at least two fetal compartments due to fetal heart failure secondary to anemia) or erythroblastosis fetalis (moderate to severe immune-mediated hemolytic anemia)

Standard dose of 300 µg of Rhogam® sufficient for 30 mL of fetal blood. Give additional 10 µg of Rhogam® for every mL of fetal blood over 30 mL

Counselling of the Pregnant Woman

Nutrition

- Canada's Food Guide to Healthy Eating suggests
 - 3-4 servings of milk products daily (greater if multiple gestation)
 - a daily caloric increase of ~100 cal/d in the 1st trimester, ~300 cal/d in the second and third trimesters and ~450 cal/d during lactation
 - daily multivitamin should be continued in the 2nd trimester for women who do not consume an adequate diet; otherwise, routine vitamin supplementation is not necessary (avoid excess vitamin A)
- nutrients important during pregnancy
 - folate: 0.4 mg/d for first 12 wk (5 mg/d if high risk)
 - ♦ supports increase in blood volume, growth of maternal and fetal tissue, decreases incidence of NTD
 - ♦ foods rich in folic acid include: spinach, lentils, chick peas, asparagus, broccoli, peas, brussels sprouts, corn, and oranges
 - calcium: 1200-1500 mg/d
 - ♦ maintains integrity of maternal bones, skeletal development of fetus, breast milk production
 - vitamin D: 1,000 IU
 - ♦ promotes calcium absorption
 - iron: 0.8 mg/d in T1, 4-5 mg/d in T2, and >6 mg/d in T3
 - ♦ supports maternal increase in blood cell mass, supports fetal and placental tissue
 - ♦ required amounts exceed normal body stores and typical intake, and therefore need supplemental iron
 - ♦ iron is the only known nutrient for which requirements during pregnancy cannot be met by diet alone (*see Iron Deficiency Anemia, OB25*)
 - essential fatty acids – supports fetal neural and visual development
 - ♦ contained in vegetable oils, margarines, peanuts, fatty fish

Caffeine

- diuretic and stimulant that readily crosses placenta
- less than 300 mg/d is not thought to contribute to miscarriage or preterm birth (ACOG)
- relationship between caffeine and IUGR is unknown (ACOG)
- SOGC states 1-2 cups/d are safe during pregnancy

Herbal Teas and Preparations

- not enough scientific information about safety of various herbs and herbal products to recommend their use during pregnancy
- some herbal teas can have toxic or pharmacological effects on the mother or fetus
- chamomiles have been reported to exhibit adverse effects on the uterus
- raspberry leaf tea often used at term to promote labour

Sources of Caffeine

- 5 oz cup coffee: 40-180 mg
- 5 oz brewed tea: 20-90 mg
- 12 oz cola: 46 mg
- Red Bull®: 67 mg
- Dark chocolate bar: 10 mg
- 8 oz hot chocolate: 5 mg

Herbal Teas Considered Safe in Moderation (2-3 cups/d)

- Citrus peel
- Ginger
- Lemon balm
- Linden flower – not with prior cardiac condition
- Orange peel
- Rose hip

Foodborne Illnesses

- microbiological contamination of food may occur through cross-contamination and/or improper food handling
 - listeriosis (*Listeria monocytogenes*) and toxoplasmosis (*Toxoplasma gondii*) are of concern during pregnancy
 - avoid consumption of raw meats, fish, shellfish, poultry, hotdogs, raw eggs, and unpasteurized dairy products
 - avoid unpasteurized soft cheeses, deli meats, smoked salmon, and pates as they may be sources of *Listeria*
- chemical contamination of food
 - current guideline for mercury of 0.5 ppm in fish is not considered harmful for the general population, including pregnant women
 - Health Canada advises pregnant women to limit consumption of top predator fish such as shark, swordfish, king mackerel, tilefish

Lifestyle

- exercise under physician guidance; “talk test” = should be able to speak while exercising; avoid supine position after 20 weeks GA
 - absolute contraindications
 - ruptured membranes, preterm labour, hypertensive disorders of pregnancy, incompetent cervix, IUGR, multiple gestations (>3), placenta previa after 28th wk, persistent 2nd or 3rd trimester bleeding, uncontrolled type 1 DM, uncontrolled thyroid disease, or other serious cardiovascular, respiratory, or systemic disorder
 - relative contraindications
 - previous preterm birth, mild/moderate cardiovascular or respiratory disorder, anemia (Hb \leq 100 g/L), malnutrition or eating disorder, twin pregnancy after 28th wk, other significant medical conditions
- weight gain: optimal gain depends on pre-pregnancy BMI (varies from 6.8-18.2 kg)
- work: strenuous work, extended hours and shift work during pregnancy may be associated with greater risk of low birth weight, prematurity, and spontaneous abortion
- air travel is acceptable in second trimester; airline cut off for travel is 36-38 wk gestation depending on the airline, to avoid giving birth on the plane
- sexual intercourse: may continue, except in patients at risk for: abortion, preterm labour, or placenta previa; breast stimulation may induce uterine activity and is discouraged in high-risk patients near term
- smoking: assist/encourage to reduce or quit smoking
 - increased risk of decreased birth weight, placenta previa/abruption, spontaneous abortion, preterm labour, stillbirth
- alcohol: no amount of alcohol is safe in pregnancy; encourage abstinence from alcohol during pregnancy; alcohol increases incidence of abortion, stillbirth, and congenital anomalies
 - fetal alcohol syndrome (see [Pediatrics, P24](#))
- cocaine: microcephaly, growth retardation, prematurity, abruptio placentae
- biopsychosocial considerations: discuss birth plan, offer community maternal resources

Expected Weight Gain	
BMI (kg/m ²)	Weight (kg)
<19	12.7-18.2
19-25	11.3-15.9
>25	6.8-11.3

General Rule: 1-3.5 kg/wk during T1, then 0.45 kg/wk until delivery

Drug Resources During Pregnancy and Breastfeeding

- Motherisk at the Hospital for Sick Children in Toronto: www.motherisk.org
- Hale T. Medications and mothers' milk, 11th ed. Pharmasoft Publishing, 2004
- Lactmed: <https://toxnet.nlm.nih.gov/newtoxnet/lactmed.htm>

Medications

- most drugs cross the placenta to some extent
- very few drugs are teratogenic, but very few drugs have proven safety in pregnancy
- use any drug with caution and only if necessary
- analgesics: acetaminophen preferable to ASA or ibuprofen

Table 5. Documented Adverse Effects, Contraindicated

Contraindicated Medication	Adverse Effect
ACEI	Fetal renal defects, IUGR, oligohydramnios
Tetracycline	Stains infant's teeth, may affect long bone development
Retinoids (e.g. Accutane®)	CNS, craniofacial, cardiac, and thymic anomalies
Misoprostol	Mobius syndrome (congenital facial paralysis with or without limb defects), spontaneous abortion, preterm labour

Table 6. Documented Adverse Effects, Weigh Benefits vs. Risks, and Consider Medication Change

Medication	Adverse Effect
Phenytoin	Fetal hydantoin syndrome in 5-10% (IUGR, mental retardation, facial dysmorphogenesis, congenital anomalies)
Valproate	ONTD in 1%
Carbamazepine	ONTD in 1-2%
Lithium	Ebstein's cardiac anomaly, goitre, hyponatremia
Warfarin	Increased incidence of spontaneous abortion, stillbirth, prematurity, IUGR, fetal warfarin syndrome (nasal hypoplasia, epiphyseal stippling, optic atrophy, mental retardation, intracranial hemorrhage)
Erythromycin	Maternal liver damage (acute fatty liver)
Sulpha drugs	Anti-folate properties, therefore theoretical risk in T1; risk of kernicterus in T3
Chloramphenicol	Grey baby syndrome (fetal circulatory collapse 2° to toxic accumulation)

Immunizations

Intrapartum

- administration is dependent on the risk of infection vs. risk of immunization complications
- safe: tetanus toxoid, diphtheria, influenza, hepatitis B, pertussis
- avoid live vaccines (risk of placental and fetal infection): polio, measles/mumps/rubella, varicella
- contraindicated: oral typhoid
- the Public Health Agency of Canada recommends:
 - all pregnant women receive the influenza vaccine
 - all pregnant women at 26 weeks of pregnancy or later, who have not received a dose of pertussis-containing vaccine in adulthood, should receive Tdap vaccination in pregnancy

Postpartum

- rubella vaccine for all non-immune mothers. If they've had an adult booster and remain non-immune, they should not be revaccinated
- hepatitis B vaccine should be given to infant within 12 h of birth if maternal status unknown or positive – follow-up doses at 1 and 6 mo
- any vaccine required/recommended is generally safe postpartum

Radiation

- ionizing radiation exposure is considered teratogenic at high doses
 - if indicated for maternal health, should be done
- imaging not involving direct abdominal/pelvic high dosage radiation is not associated with adverse effects
 - higher dosage to fetus: plain x-ray of lumbar spine/abdomen/pelvis, barium enema, CT abdomen, pelvis, lumbar spine
- most investigations involve minimal radiation exposure
- radioactive isotopes of iodine are contraindicated
- no known adverse effects from U/S or MRI (long-term effects of gadolinium unknown, avoid if possible)

Table 7. Approximate Fetal Doses from Common Diagnostic Procedures

Examination	Estimated Fetal Dose (rad)	Number of Exams Safe in Pregnancy
Plain Film		
Abdomen	0-14	35
Pelvis	0-11	45
Lumbar spine	0-17	29
Thoracic spine	0.009	555
Chest (2 views)	<0.001	5000
CT		
Abdomen	0-8	6
Pelvis	2-5	2
Lumbar spine	0-24	20
Chest	0.006	833

Adapted from: Cohen-Kerem, et al. 2005 and Valentin 2000

Radiation in Pregnancy

- Necessary amount to cause miscarriage: > 5 rads
- Necessary amount to cause malformations: > 20-30 rads

Antenatal Fetal Surveillance

Fetal Movements

- patients will generally first notice fetal movement ("quickening") at 18-20 wk in primigravidas; can occur 1-2 wk earlier in multigravidas; can occur 1-2 wk later if placenta is implanted on the anterior wall of uterus
- if the patient is concerned about decreased fetal movement, she is counselled to choose a time when the fetus is normally active to count movements (usually recommended after 26 wk)
- all high risk women should be told to do FM counts
 - if there is a subjective decrease in fetal movement, try drinking juice, eating, changing position, or moving to a quiet room and count for 2 h; ≥ 6 movements in 2 h expected
 - if there are < 6 movement counts in 2 h, patient should present to labour and delivery triage

DDx of Decreased Fetal Movements

DASH
 Death of fetus
 Amniotic fluid decreased
 Sleep cycle of fetus
 Hunger/Thirst

Normal NST: 2 accels, > 15 bpm from baseline, lasting > 15 s in 20 min

NON-STRESS TEST

Definition

- FHR tracing ≥ 20 min using an external Doppler to assess FHR and its relationship to fetal movement (see *Fetal Monitoring in Labour, OB33*)

Indication

- any suggestion of uteroplacental insufficiency or suspected compromise in fetal well-being

Table 8. Classification of Antepartum Non-Stress Test

Parameter	Normal NST (Previously "Reactive")	Atypical NST (Previously "Non-Reactive")	Abnormal NST (Previously "Non-Reactive")
Baseline	110-160 bpm	100-110 bpm or > 160 bpm for < 30 min Rising baseline	Bradycardia < 100 bpm Tachycardia > 160 for > 30 min Erratic baseline
Variability	6-25 bpm (moderate) ≤ 5 (absent or minimal) for < 40 min	5 (absent or minimal) for 40-80 min	≤ 5 for 80 min Sinusoidal 25 bpm for > 10 min
Decelerations	None or occasional variable < 30 s	Variable decelerations 30-60 s duration	Variable decelerations > 60 s Late deceleration(s)
Accelerations in Term Fetus	2 accelerations with acme of ≥ 15 bpm, lasting 15 s over < 40 min of testing	2 accelerations with acme of ≥ 15 bpm, lasting 15 s in 40-80 min	< 2 accelerations with acme of ≥ 15 bpm, lasting 15 s in > 80 min
Accelerations in Preterm Fetus (< 32 wk)	> 2 accelerations with acme of > 10 bpm, lasting 10 s in < 40 min	< 2 accelerations with acme of > 10 bpm, lasting 10 s in 40-80 min	< 2 accelerations with acme of > 10 bpm, lasting 10 s in > 80 min
Action	FURTHER ASSESSMENT OPTIONAL, based on total clinical picture	FURTHER ASSESSMENT REQUIRED	URGENT ACTION REQUIRED An overall assessment of the situation and further investigation with U/S or BPP is required; some situations will require delivery

Adapted from: SOGC, Fetal Health Surveillance: Antepartum and Intrapartum Consensus Guideline, September 2007

Operating Characteristics

- false positive rate depends on duration; false negative rate = 0.2-0.3%

Interpretation

- normal: at least 2 accelerations of FHR > 15 bpm from the baseline lasting > 15 s in 20 min
- abnormal: < 2 accelerations of FHR in 40 min
- if no observed accelerations or fetal movement in the first 20 min, stimulate fetus (fundal pressure, acoustic/vibratory stimulation) and continue monitoring for 30 min

BIOPHYSICAL PROFILE

Definition

- U/S assessment of the fetus \pm NST

Indications

- post-term pregnancy
- decreased fetal movement
- IUGR
- any other suggestion of fetal distress or uteroplacental insufficiency

Operating Characteristics

- false positive rate $\leq 30\%$, false negative rate = 0.1%

Table 9. Scoring of the BPP

Parameter	Reassuring (2 points)
Tone (limb extension then flexion)	
At least one episode of limb extension followed by flexion	
Movement	Three discrete movements
Breathing	At least one episode of breathing lasting at least 30 s
AFV*	Fluid pocket of 2 cm in 2 axes

*AFV is a marker of chronic hypoxia, all other parameters indicate acute hypoxia

Interpretation

- 8: perinatal mortality rate 1:1,000; repeat BPP as clinically indicated
- 6: perinatal mortality 31:1,000; repeat BPP in 24 h
- 0-4: perinatal mortality rate 200:1,000; deliver fetus if benefits of delivery outweigh risks

Reassuring BPP (8/8)

LAMB

- Limb extension + flexion
- AFV 2 cm x 2 cm
- Movement (3 discrete)
- Breathing (one episode x 30 s)

Obstetrical Hemorrhage

Definition

- vaginal bleeding from 20 wk to term

Differential Diagnosis

- bloody show (shedding of cervical mucous plug) – most common etiology in T3
- placenta previa
- abruptio placentae – most common pathological etiology in T3
- vasa previa
- cervical lesion (cervicitis, polyp, ectropion, cervical cancer)
- uterine rupture
- other: bleeding from bowel or bladder, abnormal coagulation

Table 10. Comparison of Placenta Previa and Abruptio Placentae

	Placenta Previa	Abruptio Placentae
Definition	Abnormal location of the placenta near, partially, or completely over the internal cervical os	Premature separation of a normally implanted placenta after 20 wk GA
Etiology	Idiopathic	Idiopathic
Epidemiology	0.5-0.8% of all pregnancies	1-2% of all pregnancies
Risk Factors	History of placenta previa (4-8% recurrence risk) Multiparity Increased maternal age Multiple gestation Uterine tumour (e.g. fibroids) or other uterine anomalies Uterine scar due to previous abortion, C/S, D&C, myomectomy	Previous abruption (recurrence rate 5-16%) Maternal HTN (chronic or gestational HTN in 50% of abruptions) or vascular disease Cigarette smoking (> 1 pack/d), excessive alcohol consumption, cocaine Multiparity and/or maternal age > 35 yr PPROM Rapid decompression of a distended uterus (polyhydramnios, multiple gestation) Uterine anomaly, fibroids Trauma (e.g. motor vehicle collision, maternal battery)
Bleeding	PAINLESS	Usually PAINFUL

Placenta Previa

Definition

- placenta implanted in the lower segment of the uterus, presenting ahead of the leading pole of the fetus
- placental position is described in relation to the internal os as “mm away” or “mm of overlap”

Clinical Features

- PAINLESS bright red vaginal bleeding (recurrent), may be minimized and cease spontaneously but can become catastrophic
- mean onset of bleeding is 30 wk GA, but onset depends on degree of previa
- physical exam**
 - do not perform pelvic exam until ruling out placenta previa
 - uterus soft and non-tender
 - presenting fetal part high or displaced
 - FHR usually normal
 - shock/anemia correspond to degree of apparent blood loss

Greater than 20 mm of overlap over the internal os in the third trimester of pregnancy is highly predictive of the need for a C/S. Any degree of overlap after 35 wk is an indication for a C/S

• complications

- fetal
 - ♦ perinatal mortality low but still higher than with a normal pregnancy
 - ♦ prematurity (bleeding often dictates early C/S)
 - ♦ intrauterine hypoxia (acute or IUGR)
 - ♦ fetal malpresentation
 - ♦ PPRM
 - ♦ risk of fetal blood loss from placenta, especially if incised during C/S
- maternal
 - ♦ <1% maternal mortality
 - ♦ hemorrhage and hypovolemic shock, anemia, acute renal failure, pituitary necrosis (Sheehan syndrome)
 - ♦ placenta accreta – especially if previous uterine surgery, anterior placenta previa
 - ♦ hysterectomy

Investigations

- transvaginal U/S is more accurate than transabdominal U/S at diagnosing placenta previa at any gestational age
- if the placenta lies between 20 mm of overlap and 20 mm away from the internal os after 20 wk, transvaginal ultrasounds should be repeated in the third trimester as continued change in the placental location is likely

Do NOT perform a vaginal exam until placenta previa has been ruled out by U/S

Management

- goal: keep pregnancy intrauterine until the risk of delivery < risk of continuing pregnancy
- stabilize and monitor
 - maternal stabilization: large bore IV with hydration, O₂ for hypotensive patients
 - maternal monitoring: vitals, urine output, blood loss, blood work (hematocrit, CBC, INR/PTT, platelets, fibrinogen, FDP, type and cross match)
 - electronic fetal monitoring
 - U/S assessment: when fetal and maternal condition permit, determine fetal viability, gestational age, and placental status/position
- Rhogam® if mother is Rh negative
- determine extent of fetomaternal transfusion so that appropriate dose of Rhogam® can be given
- GA <37 wk and minimal bleeding: expectant management
 - admit to hospital
 - limited physical activity, no douches, enemas, or sexual intercourse
 - consider corticosteroids for fetal lung maturity
 - delivery when fetus is mature or hemorrhage dictates due to maternal or fetal compromise
- GA ≥37 wk, profuse bleeding, or L/S ratio is >2:1 – deliver by C/S

Abruptio Placentae

Definition

- premature partial or total placental detachment caused by bleeding at the decidual-placental interface
- occurring >20 wk gestation

Clinical Features

- classification
 - total (fetal death inevitable) vs. partial
 - external/revealed/apparent: blood dissects downward toward cervix
 - internal/concealed/occult (20%): blood dissects upward toward fetus
 - most are mixed
- presentation
 - usually PAINFUL (80%) vaginal bleeding (bleeding not always present if abruption is concealed), uterine tenderness, uterine contractions/hypertonus
 - pain: sudden onset, constant, localized to lower back and uterus
 - shock/anemia out of proportion to apparent blood loss
 - ± fetal distress, fetal demise (15% present with demise), bloody amniotic fluid (fetal presentation typically normal)
 - ± coagulopathy

Abruptio placentae is the most common cause of DIC in pregnancy

Complications

- fetal complications: perinatal mortality 25-60%, prematurity, intrauterine hypoxia
- maternal complications: <1% maternal mortality, DIC (in 20% of abruptions), acute renal failure, anemia, hemorrhagic shock, pituitary necrosis (Sheehan syndrome), amniotic fluid embolus

Investigations

- clinical diagnosis, U/S not sensitive for diagnosing abruption (sensitivity = 15%)

Management

- maternal stabilization: large bore IV with hydration, O₂ for hypotensive patients
- maternal monitoring: vitals, urine output, blood loss, bloodwork (hematocrit, CBC, PTT/PT, platelets, fibrinogen, FDP, type and cross match)

- EFM
- blood products on hand (red cells, platelets, cryoprecipitate) because of DIC risk
- Rhogam® if Rh negative
 - Kleihauer-Betke test may confirm abruption
- mild abruption
 - GA <37 wk: use serial Hct to assess concealed bleeding, deliver when fetus is mature or when hemorrhage dictates
 - GA ≥37 wk: stabilize and deliver
- moderate to severe abruption
 - hydrate and restore blood loss and correct coagulation defect if present
 - vaginal delivery if no contraindication and no evidence of fetal or maternal distress or fetal demise
 - C/S if live fetus and fetal or maternal distress develops with fluid/blood replacement, labour fails to progress, or if vaginal delivery otherwise contraindicated

Kleihauer-Betke Test
Quantifies fetal cells in the maternal circulation

Vasa Previa

Definition

- unprotected fetal vessels pass over the cervical os; associated with velamentous insertion of cord into membranes of placenta or succenturiate (accessory) lobe

Epidemiology

- 1 in 5,000 deliveries – higher in twin pregnancies

Clinical Features

- PAINLESS vaginal bleeding and fetal distress (tachy-to-bradyarrhythmia in a sinusoidal pattern)
- if undiagnosed, 50% perinatal mortality, increasing to 75% if membranes rupture (most infants die of exsanguination)
- if diagnosed antenatally on ultrasound without labour or symptoms, then 97% survival

Investigations

- Apt test (NaOH mixed with the blood) can be done immediately to determine if the source of bleeding is fetal (supernatant turns pink) or maternal (supernatant turns yellow)
- Wright stain on blood smear and look for nucleated red blood cells (in cord, not maternal blood)

Management

- emergency C/S (since bleeding is from fetus, a small amount of blood loss can have catastrophic consequences)

Figure 3. Vasa previa

Obstetrical Complications

Preterm Labour

Definition

- labour between 20 and 37 wk gestation

Etiology

- idiopathic (most common)
- maternal: infection (recurrent pyelonephritis, untreated bacteriuria, chorioamnionitis), HTN, DM, chronic illness, mechanical factors; previous obstetric, gynecological, and abdominal surgeries; socio-environmental (poor nutrition, smoking, drugs, alcohol, stress)
- maternal-fetal: PPRM (common), polyhydramnios, placenta previa, placental abruption, or placental insufficiency
- fetal: multiple gestation, congenital abnormalities of fetus, fetal hydrops, stress
- uterine: excessive enlargement (hydramnios, multiple gestation), malformations (intracavitary leiomyomas, septate uterus, mullerian duct abnormalities)

Epidemiology

- preterm labour complicates about 10% of pregnancies

Risk Factors

- prior history of spontaneous PTL is the most important risk factor
- prior history of large or multiple cervical excisions (cone biopsy) or mechanical dilatation (D&C)
- cervical length: measured by transvaginal U/S (cervical length >30 mm has high negative predictive value for PTL before 34 wk)
- identification of bacterial vaginosis and ureaplasma urealyticum infections; routine screening not supported by current data, but it is reasonable to screen high-risk women
- family history of preterm birth
- smoking
- late maternal age
- multiple gestation

Preterm labour is the most common cause of neonatal mortality in the US

Predicting PTL

- fetal fibronectin: a glycoprotein in amniotic fluid and placental tissue
 - positive if >50 ng/mL; NPV $>$ PPV
 - in symptomatic women (i.e. preterm contractions), fetal fibronectin is most effectively combined with U/S detecting cervical length
 - if cervical length is not short and fetal fibronectin is negative, preterm labour is highly unlikely

Clinical Features

- regular contractions (2 in 10 min, $>6/h$)
- cervix >1 cm dilated, $>80\%$ effaced, or length <2.5 cm

Management

A. Initial

- transfer to appropriate facility if stable
- hydration (NS at 150 mL/h)
- bed rest in LDDP
- sedation (morphine)
- avoid repeated pelvic exams (increased infection risk)
- U/S examination of fetus (GA, BPP, position, placenta location, estimated fetal weight)
- prophylactic antibiotics; (for GBS) important to consider if PPRM (e.g. erythromycin controversial, but may help to delay delivery)

B. Suppression of Labour – Tocolysis

- does not inhibit preterm labour completely, but may delay delivery (used for <48 h) to allow for betamethasone valerate (Celestone[®]) and/or transfer to appropriate centre for care of the premature infant
- requirements (all must be satisfied)
 - preterm labour
 - live, immature fetus, intact membranes, cervical dilatation of <4 cm
 - absence of maternal or fetal contraindications
- contraindications
 - maternal: bleeding (placenta previa or abruption), maternal disease (HTN, DM, heart disease), preeclampsia or eclampsia, chorioamnionitis
 - fetal: erythroblastosis fetalis, severe congenital anomalies, fetal distress/demise, IUGR, multiple gestation (relative)
- agents
 - calcium channel blockers: nifedipine
 - 20 mg PO loading dose followed by 20 mg PO 90 min later
 - 20 mg can be continued q3-8h for 72 h or to a max of 180 mg
 - 10 mg PO q20min x 4 doses
 - contraindications: nifedipine allergy, hypotension, hepatic dysfunction, concurrent beta-mimetics or $MgSO_4$ use, transdermal nitrates, or other antihypertensive medications
 - prostaglandin synthesis inhibitors: indomethacin
 - 1st line for early preterm labour (<30 wk GA) or polyhydramnios
 - 50-100 mg PR loading dose followed by 50 mg q6h x 8 doses for 48 hours
 - magnesium sulphate
 - was previously used for tocolysis; currently, only indicated for prevention of eclampsia or for neuroprotection if preterm delivery is inevitable between 24 and 31+6 wks GA for neuroprotection
 - 4 g IV loading dose followed by 1g q1h maintenance until birth

C. Enhancement of Fetal Pulmonary Maturity

- betamethasone valerate (Celestone[®]) 12 mg IM q24h x 2 doses or dexamethasone 6 mg IM q12h x 4 doses
 - 28-36+6 wk GA: reduces incidence of RDS
 - 24-28 wk GA: reduces severity of RDS, overall mortality and rate of IVH
 - specific maternal contraindications: active TB

D. Cervical Cerclage

- definition: placement of cervical sutures at the level of the internal os, usually at the end of the first trimester or in the second trimester and removed in the third trimester
- indications: cervical incompetence (i.e. cervical dilation and effacement in the absence of increased uterine contractility)
 - emerging evidence indicates that progesterone suppositories are superior to cerclage in preventing preterm labour of singletons not due to cervical incompetence
- diagnosis of cervical incompetence
 - obstetrical Hx: silent cervical dilation, 2nd trimester losses, procedures on cervix
 - ability of cervix to hold an inflated Foley catheter during a hysterosonogram
- proven benefit in the prevention of PTL in women with primary structural abnormality of the cervix (e.g. conization of the cervix, connective tissue disorders)

Positive fetal fibronectin in cervicovaginal fluid (>50 ng/mL) at 24 wk gestation predicted spontaneous PTL at <34 wk with sensitivity of 23%, specificity of 97%, PPV of 25%, NPV of 96%

Tocolytics for Preterm Premature Rupture of Membranes

Cochrane DB Syst Rev 2014;2:CD007062

Purpose: To assess the potential benefits and harms of tocolysis in women with PPRM.

Selection Criteria: Pregnant women with singleton pregnancies and PPRM (23-36 wk and 6 d GA).

Results: 8 studies with 408 women total.

Prophylactic tocolysis with PPRM was associated with increased overall latency, without additional benefits for maternal/neonatal outcomes. For women with PPRM before 34 wk, there was a significantly increased risk of chorioamnionitis in women who received tocolysis. Neonatal outcomes were not significantly different.

Conclusion: Although there are limitations to the studies, there is currently insufficient evidence to support tocolytic therapy for women with PPRM, as there was an increase in maternal chorioamnionitis without significant benefits to the infant.

Cerclage for Short Cervix on Ultrasonography in Women With Singleton Gestations and Previous Preterm Birth

Obstet Gynecol 2011;117:663-671

Purpose: To determine if cerclage prevents preterm birth (<35 wk gestation) and perinatal mortality and morbidity among women with previous spontaneous preterm birth, asymptomatic singleton gestation, and short cervical length (<25 mm before 24 wk gestation) on transvaginal ultrasonography.

Methods: Meta-analysis of randomized trials identified using searches on MEDLINE, PUBMED, EMBASE, and the Cochrane Library.

Results: 5 trials included. Preterm birth was significantly lower among women receiving cerclage vs. those not receiving (RR = 0.70, 95% CI 0.55-0.89). Cerclage also significantly reduced preterm birth before 24, 28, 32, and 37 wk gestation. Perinatal mortality and morbidity were significantly lower in the cerclage group (RR = 0.64, 95% CI 0.45-0.91).

Conclusions: Cerclage significantly prevents preterm birth and perinatal mortality and morbidity in this specific group of women.

Antenatal Betamethasone for Women at Risk for Late Preterm Delivery

N Engl J Med 2016 Apr; 374:1311-20.

Purpose: This was a randomized trial comparing betamethasone (n = 1429) to placebo (n = 1402) in the treatment of women with a singleton pregnancy between 34 to 36 + 5/7 wk that were at high risk of delivery. Composite endpoints assessing the need for respiratory support within 72 h of birth were used to measure treatment effectiveness. Specifically, these endpoints included: supplemental oxygen, extracorporeal membrane oxygenation (ECMO), mechanical ventilation, and CPAP or high-flow nasal cannula.

Results: The primary outcome occurred less frequently in those who received betamethasone (11.6% vs. 14.4%, RR 0.8, p = 0.02). Treatment with betamethasone also significantly reduced additional respiratory complications, bronchopulmonary dysplasia, transient tachypnea of the newborn, and surfactant use.

Conclusion: Treating women (GA 34 to 36 + 5/7 wk) who are at risk of delivery with betamethasone reduces the risk of neonatal complications.

Prognosis

- prematurity is the leading cause of perinatal morbidity and mortality
- 30 wk or 1,500 g (3.3 lb) = 90% survival
- 33 wk or 2,000 g (4.4 lb) = 99% survival
- morbidity due to asphyxia, hypoxia, sepsis, RDS, intraventricular cerebral hemorrhage, thermal instability, retinopathy of prematurity, bronchopulmonary dysplasia, necrotizing enterocolitis

Prevention of Preterm Labour

- currently there are no agents approved by Health Canada to arrest preterm labour
- preventative measures: good prenatal care, identify pregnancies at risk, treat silent vaginal infection or UTIs, patient education
- transvaginal ultrasound of cervical length is recommended only for high-risk pregnancies and only before 30 weeks GA

Premature Rupture of Membranes

Definitions

- PROM: pre-labour rupture of membranes at any GA
- prolonged ROM: >24 h elapsed between rupture of membranes and onset of labour
- preterm ROM: ROM occurring before 37 wk gestation
- PPRM: preterm (before 37 wk) AND pre-labour rupture of membranes

Risk Factors

- maternal: multiparity, cervical incompetence, infection (cervicitis, vaginitis, STI, UTI), family history of PROM, low socioeconomic class/poor nutrition
- fetal: congenital anomaly, multiple gestation
- other risk factors associated with PTL

Clinical Features

- history of fluid gush or continued leakage

Investigations

- sterile speculum exam (avoid introduction of infection)
 - pooling of fluid in the posterior fornix
 - may observe fluid leaking out of cervix on cough/Valsalva (“cascade”)
- nitrazine (basic amniotic fluid turns nitrazine paper blue)
 - low specificity as it can also be positive with blood, urine, or semen
- ferning (high salt in amniotic fluid evaporates, looks like ferns under microscope)
- U/S to rule out fetal anomalies; assess GA, presentation, and BPP

Management

- admit for expectant management and monitor vitals q4h, daily BPP and WBC count
- avoid introducing infection by minimizing examinations
 - consider administration of betamethasone valerate (Celestone®) to accelerate maturity if <34 wk and up to 36+6 weeks if no evidence of infection
 - consider tocolysis for 48 h to permit administration of steroids if PPRM induces labour
- screen women for UTIs, STIs, GBS infection and treat with appropriate antibiotics if positive (treat GBS at time of labour)
- if not in labour or labour not indicated, consider antibiotics: penicillins or macrolide antibiotics are the antibiotics of choice
- deliver urgently if evidence of fetal distress and/or chorioamnionitis

Table 11. PROM Management

Degree of Prematurity	Management
<24 wk	Consider termination (poor outcome due to pulmonary hypoplasia)
24-25 wk	Individual consideration with counselling of parents regarding risks to preterm infants
26-34 wk	Expectant management as prematurity complications are significant
34-36 wk	“Grey zone” where risk of death from RDS and neonatal sepsis is the same
≥37 wk	Induction of labour since the risk of death from sepsis is greater than RDS

Prognosis

- varies with gestational age
- 90% of women with PROM at 28-34 wk GA go into spontaneous labour within 1 wk
- 50% of women with PROM at <26 wk GA go into spontaneous labour within 1 wk
- complications: cord prolapse, intrauterine infection (chorioamnionitis), premature delivery, limb contracture

Membrane status determined by

- Pooling of fluid on speculum exam
- Increased pH of vaginal fluid (nitrazine test)
- Ferning of fluid under light microscopy
- Decreased AFV on U/S

Antibiotic Therapy in Preterm Premature Rupture of the Membranes

J Obstet Gynaecol Can 2009;31(9):863-7.

Study: A review of recent systematic reviews, randomized control trials/controlled trials, and observational studies assessing the use of antibiotics in PPRM.

Recommendations:

1. Following PPRM at ≤32 wk gestation, antibiotics should be administered to women who are not in labour in order to prolong pregnancy and to decrease maternal and neonatal morbidity. (I-A)
2. The use of antibiotics should be gestational-age dependent. The evidence for benefit is greater at earlier gestational ages (< 32 wk). (I-A)
3. For women with PPRM at >32 wk gestation, administration of antibiotics to prolong pregnancy is recommended if fetal lung maturity cannot be proven and/or delivery is not planned. (I-A)
4. Antibiotic regimens may consist of an initial parenteral phase followed by an oral phase, or may consist of only an oral phase. (I-A)
5. Antibiotics of choice are penicillins or macrolide antibiotics (erythromycin) in parenteral and/or oral forms. (I-A) In patients allergic to penicillin, macrolide antibiotics should be used alone. (III-B)
6. The following two regimens may be used (the two regimens were used in the largest PPRM randomized controlled trials that showed a decrease in both maternal and neonatal morbidity): (1) ampicillin 2 g IV every 6 h and erythromycin 250 mg IV every 6 h for 48 h, followed by amoxicillin 250 mg PO every 8 h and erythromycin 333 mg PO every 8 h for 5 days (I-A); (2) erythromycin 250 mg PO every 6 h for 10 d (I-A)
7. Amoxicillin/clavulanic acid should not be used because of an increased risk of necrotizing enterocolitis in neonates exposed to this antibiotic. Amoxicillin without clavulanic acid is safe. (I-A)
8. Women presenting with PPRM should be screened for urinary tract infections, sexually transmitted infections, and group B *Streptococcus* carriage, and treated with appropriate antibiotics if positive. (II-2B)

*Evidence was approved by the Maternal Fetal Medicine Committee and Infectious Disease Committee of the Society of Obstetricians and Gynecologists of Canada

Postterm Pregnancy

Definition

- pregnancy >42 wk GA

Epidemiology

- 41 wk GA: up to 27%
- >42 wk GA: 5.5%

Etiology

- most cases idiopathic
- anencephalic fetus with no pituitary gland
- placental sulfatase deficiency (X-linked recessive condition in 1/2,000-1/6,000 infants) – rare

Clinical Features

- postmaturity syndrome (10-20% of post-term pregnancies): fetal weight loss, reduced subcutaneous fat, scaling, dry skin from placental insufficiency, long thin body, open-eyed, alert and worried look, long nails, palms and soles wrinkled
- with increasing GA, higher rates of: intrauterine infection, asphyxia, meconium aspiration syndrome, placental insufficiency, placental aging and infarction, macrosomia, dystocia, fetal distress, operative deliveries, pneumonia, seizures, and requirement of NICU admission, stillbirth

Management

- GA 39 wk with advanced maternal age (>40yo): consideration should be given to IOL due to increased risk of stillbirth
- GA 40-41 wk: expectant management
 - no evidence to support IOL or C/S unless other risk factors for morbidity are present (see prognosis)
- GA >41 wk: offer IOL if vaginal delivery is not contraindicated
 - IOL shown to decrease C/S, fetal heart rate changes, meconium staining, macrosomia, and death when compared with expectant management
- GA >41 wk and expectant management elected: serial fetal surveillance
 - fetal movement count by the mother
 - BPP q3-4d
- if AFI is decreased, labour should be induced

Prognosis

- if >42 wk, perinatal mortality 2-3x higher (due to progressive uteroplacental insufficiency)
- morbidity increased with HTN in pregnancy, DM, abruption, IUGR, and multiple gestation

Intrauterine Fetal Death (Demise)

Definition

- fetal death in utero after 20 wk GA (before 20 wk GA called spontaneous abortion)

Epidemiology

- occurring in 1% of pregnancies

Etiology

- 50% idiopathic
- 50% secondary to HTN, DM, erythroblastosis fetalis, congenital anomalies, umbilical cord or placental complications, intrauterine infection, APS

Clinical Features

- decreased perception of fetal movement by mother
- SFH and maternal weight not increasing
- absent fetal heart tones on Doppler (not diagnostic)
- high MSAFP
- on U/S: no fetal heart rate. Depending on timing of death, may see skull collapse, brain tissue retraction, empty fetal bladder, non-filled aorta, poor visualization of midline flux

Management

- diagnosis: absent cardiac activity and fetal movement on U/S required for diagnosis
- determine secondary cause
 - maternal: HbA1c, fasting glucose, TSH, Kleihauer-Betke, VDRL, ANA, CBC, anticardiolipins, antibody screens, INR/PTT, serum/urine toxicology screens, cervical and vaginal cultures, TORCH screen
 - fetal: karyotype, cord blood, skin biopsy, genetics evaluation, autopsy, amniotic fluid culture for CMV, parvovirus B19, herpes
 - placenta: pathology, bacterial cultures

DIC: Generalized Coagulation and Fibrinolysis Leading to Depletion of Coagulation Factors

Obstetrical Causes

- Abruption
- Gestational HTN
- Fetal demise
- PPH

DIC-specific Blood Work

- Platelets
- aPTT and PT
- FDP
- Fibrinogen

Treatment

- Treat underlying cause
- Supportive
- Fluids
- Blood products
- FFP, platelets, cryoprecipitate
- Consider anti-coagulation as VTE prophylaxis

Treatment

- <12 wk: dilation and curettage
- 13-20 wk: dilation and evacuation or sometimes IOL
- >20 wk: induction of labour
- monitor for maternal coagulopathy (10% risk of DIC)
- parental psychological care/bereavement support as per hospital protocol
- comprehensive discussion within 3 mo about final investigation and post-mortem results, help make plans for future pregnancies

Intrauterine Growth Restriction**Definition**

- infant weight <10th percentile for GA or <2,500 g at term

Etiology/Risk Factors

- 50% unknown
- maternal causes
 - malnutrition, smoking, drug abuse, alcoholism, cyanotic heart disease, type 1 DM, SLE, pulmonary insufficiency, previous IUGR (25% risk, most important risk factor), chronic HTN
- maternal-fetal
 - any disease causing placental insufficiency
 - includes gestational HTN, chronic renal insufficiency, gross placental morphological abnormalities (infarction, hemangiomas, placenta previa, abnormal cord insertion), prolonged gestation
- fetal causes
 - TORCH infections, multiple gestation, congenital anomalies/chromosomal abnormalities (10%)

Clinical Features

- symmetric/type I (25-30%): occurs early in pregnancy
 - reduced growth of both head and abdomen
 - head:abdomen ratio may be normal (>1 up to 32 wk; =1 at 32-34 wk; <1 after 34 wk GA)
 - usually associated with congenital anomalies or TORCH infections
- asymmetric/type II (70%): occurs late in pregnancy
 - fetal abdomen is disproportionately smaller than fetal head
 - brain is spared, therefore head:abdomen ratio increased
 - usually associated with placental insufficiency
 - more favourable prognosis than type I
- complications
 - prone to meconium aspiration, asphyxia, polycythemia, hypoglycemia, hypocalcemia, hypophosphatemia hyponatremia, and mental retardation
 - greater risk of perinatal morbidity and mortality

Investigations

- SFH measurements at every antepartum visit
- if mother at high risk or SFH lags >2 cm behind GA
 - U/S for biparietal diameter, head and abdominal circumference ratio, femur length, fetal weight, and AFV (decrease associated with IUGR), decrease in the rate of growth
 - \pm BPP
 - Doppler analysis of umbilical cord blood flow

Management

- prevention via risk modification prior to pregnancy is ideal
- modify controllable factors: smoking, alcohol, nutrition, and treat maternal illness
- bed rest in LLDLP
- serial BPP (monitor fetal growth) and determine cause of IUGR, if possible
- delivery when extrauterine existence is less dangerous than continued intrauterine existence (abnormal function tests, absent growth, severe oligohydramnios) especially if GA >34 wk
- liberal use of C/S since IUGR fetus withstands labour poorly

Macrosomia**Definition**

- infant weight >90th percentile for a particular GA or >4,000 g

Etiology/Risk Factors

- maternal obesity, GDM, past history of macrosomic infant, prolonged gestation, multiparity

Clinical Features

- increased risk of perinatal mortality
- CPD and birth injuries (shoulder dystocia, fetal bone fracture) more common
- complications of DM in labour (see Table 15, OB27)

**TORCH**

Toxoplasmosis

Others: e.g. syphilis

Rubella

CMV

HSV

- See Table 12, OB20

**Differential Diagnosis of****Incorrect Uterine Size for Dates**

- Inaccurate dates
- Early descent of presenting part (engagement)
- Maternal: DM
- Maternal-fetal: polyhydramnios, oligohydramnios
- Fetal: abnormal karyotype, IUGR, macrosomia, fetal anomaly, abnormal lie, multiple gestation

Investigations

- serial SFH
- further investigations if mother at high risk or SFH >2 cm ahead of GA
- U/S predictors
 - polyhydramnios
 - third trimester AC >1.5 cm/wk
 - HC/AC ratio <10th percentile
 - FL/AC ratio <20th percentile

Management

- prophylactic C/S is a reasonable option where EFW >5,000 g in non-diabetic woman and EFW >4,500 g in diabetic woman
 - no evidence that prophylactic C/S improves outcomes
- risks and benefits of early induction (risk of C/S vs. risk of dystocia) must be weighed in diabetic mothers, as current research is unclear

Polyhydramnios/Oligohydramnios

Table 12. Polyhydramnios and Oligohydramnios

	Polyhydramnios	Oligohydramnios
Definition	AFI >25 cm U/S: single deepest pocket >8 cm	AFI <5 cm U/S: single deepest pocket ≤2 cm
Etiology	Idiopathic most common Maternal Type 1 DM: abnormalities of transchorionic flow Maternal-fetal Chorioangiomas Multiple gestation Fetal hydrops (increased erythroblastosis) Fetal Chromosomal anomaly (up to 2/3 of fetuses have severe polyhydramnios) Respiratory: cystic adenomatoid malformed lung CNS: anencephaly, hydrocephalus, meningocele GI: tracheoesophageal fistula, duodenal atresia, facial clefts (interfere with swallowing)	Idiopathic most common Maternal Uteroplacental insufficiency (preeclampsia, nephropathy) Medications (ACEI) Fetal Congenital urinary tract anomalies (renal agenesis, obstruction, posterior urethral valves) Demise/chronic hypoxemia (blood shunt away from kidneys to perfuse brain) IUGR Ruptured membranes: prolonged amniotic fluid leak Amniotic fluid normally decreases after 35 wk
Epidemiology	Occur in 0.2-1.6% of all pregnancies	Occur in ~4.5% of all pregnancies Severe form in <0.7% Common in pregnancies >41 wk (~12%)
Clinical Features and Complications	Uterus large for dates, difficulty palpating fetal parts and hearing FHR Maternal complications Pressure symptoms from overdistended uterus (dyspnea, edema, hydronephrosis) Obstetrical complications Cord prolapse, placental abruption, malpresentation, preterm labour, uterine dysfunction, and PPH	Uterus small for dates Fetal complications 15-25% have fetal anomalies Amniotic fluid bands (T1) can lead to Potter's facies, limb deformities, abdominal wall defects Obstetrical complications Cord compression Increased risk of adverse fetal outcomes Pulmonary hypoplasia (late-onset) Marker for infants who may not tolerate labour well
Management	Determine underlying cause Screen for maternal disease/infection Complete fetal U/S evaluation Depends on severity Mild to moderate cases require no treatment If severe, hospitalize and consider therapeutic amniocentesis	Always warrants admission and investigation Rule out ROM Fetal monitoring (NST, BPP) U/S Doppler studies (umbilical cord and uterine artery) Maternal hydration with oral or IV fluids to help increase amniotic fluid Injection of fluid via amniocentesis will improve condition for ~1 wk – may be most helpful for visualizing any associated fetal anomalies Consider delivery if term Amnio-infusion may be considered during labour via intrauterine catheter
Prognosis	2-5 fold increase in risk of perinatal mortality	Poorer with early onset High mortality related to congenital malformations and pulmonary hypoplasia when diagnosed during T2

Multi-Fetal Gestation and Malpresentation

Epidemiology

- incidence of twins is 1/80 and triplets 1/6,400 in North America
- 2/3 of twins are dizygotic (fraternal)
 - risk factors for dizygotic twins: IVF, increased maternal age, newly discontinued OCP, ethnicity (e.g. certain African regions)
- monozygous twinning occurs at a constant rate worldwide (1/250)
- determine zygosity by number of placentas, thickness of membranes, sex, blood type

Clinical Features

Table 13. Complications Associated with Multiple Gestation

Maternal	Uteroplacental	Fetal
Hyperemesis gravidarum	Increased PROM/PTL	Prematurity*
GDM	Polyhydramnios	IUGR
Gestational HTN	Placenta previa	Malpresentation
Anemia	Placental abruption	Congenital anomalies
Increased physiological stress on all systems	PPH (uterine atony)	Twin-twin transfusion
Increased compressive symptoms	Umbilical cord prolapse	Increased perinatal morbidity and mortality
C/S	Cord anomalies (velamentous insertion, 2 vessel cord)	Twin interlocking (twin A breech, twin B vertex)
		Single fetal demise

The Ps of Multiple Gestation Complications

- Increased rates of**
- Puking
 - Pallor (anemia)
 - Preeclampsia/PIH
 - Pressure (compressive symptoms)
 - PTL/PROM/PPROM
 - Polyhydramnios
 - Placenta previa/abruptio
 - PPH/APH
 - Prolonged labour
 - Cord prolapse
 - Prematurity
 - Malpresentation
 - Perinatal morbidity and mortality
 - Parental distress
 - Postpartum depression

Management

- U/S determination of chorionicity must be done within first trimester (ideally 8-12 wk GA)
- increased antenatal surveillance
 - serial U/S q 2-3wk from 24 wk GA to assess growth (uncomplicated diamniotic dichorionic)
 - increased frequency of ultrasounds in monochorionic diamniotic and monochorionic monoamniotic twins
 - Doppler flow studies weekly if discordant fetal growth (>30%)
 - BPP as needed
- may attempt vaginal delivery if twin A presents as vertex, otherwise C/S (40-50% of all twin deliveries, 15% of cases have twin A delivered vaginally and twin B delivered by C/S)
- mode of delivery depends on fetal weights, GA, presentation

Figure 4. Classification of twin pregnancies

*Indicates time of cleavage

© Qing Huang 2004

Twin-Twin Transfusion Syndrome

Definition

- formation of placental intertwin vascular anastomoses causes arterial blood from donor twin to pass into veins of the recipient twin

Epidemiology

- 10% of monochorionic twins
- concern if >30% discordance in estimated fetal weight

Clinical Features

- donor twin: IUGR, hypovolemia, hypotension, anemia, oligohydramnios
- recipient twin: hypervolemia, HTN, CHF, polycythemia, edema, polyhydramnios, kernicterus in neonatal period

Investigations

- detected by U/S screening, Doppler flow analysis

Management

- therapeutic serial amniocentesis to decompress polyhydramnios of recipient twin and decrease pressure in cavity and on placenta
- intrauterine blood transfusion to donor twin if necessary
- laparoscopic occlusion of placental vessels
- fetoscopic laser ablation of placental vascular anastomoses when indicated and if available

Breech Presentation

Definition

- fetal buttocks or lower extremity is the presenting part as determined on U/S
- complete (10%): hips and knees both flexed
- frank (60%): hips flexed, knees extended, buttocks present at cervix
 - most common type of breech presentation
 - most common breech presentation to be delivered vaginally
- incomplete (30%): both or one hip flexed and both or one knee present below the buttocks, feet or knees present first (footling breech, kneeling breech)

Epidemiology

- occurs in 3-4% of pregnancies at term (25% <28 wk)

Risk Factors

- maternal: pelvis (contracted), uterus (shape abnormalities, intrauterine tumours, fibroids, previous breech), pelvic tumours causing compression, grand multiparity
- maternal-fetal: placenta (previa), amniotic fluid (poly-/oligohydramnios)
- fetal: prematurity, multiple gestation, congenital malformations (found in 6% of breeches; 2-3% if in vertex presentations), abnormalities in fetal tone and movement, aneuploidy, hydrocephalus, anencephalus

Management

- ECV: repositioning of singleton fetus within uterus under U/S guidance
 - overall success rate of 65%
 - criteria: >36 wk GA, singleton, unengaged presenting part, reactive NST, not in labour
 - contraindications: previous T3 bleed, prior classical C/S, previous myomectomy, oligohydramnios, PROM, placenta previa, abnormal U/S, suspected IUGR, HTN, uteroplacental insufficiency, nuchal cord
 - risks: abruption, cord compression, cord accident, ROM, labour, fetal bradycardia requiring C/S (<1% risk), alloimmunization, fetal death (1:5,000)
 - method: tocometry, followed by U/S guided transabdominal manipulation of fetus with constant fetal heart monitoring
 - if patient Rh negative, give Rhogam® prior to procedure
 - better prognosis if multiparous, good fluid volume, small baby, skilled obstetrician, posterior placenta
 - ♦ pre- or early-labour ultrasound to assess type of breech presentation, fetal growth, estimated weight, placenta position, attitude of fetal head (flexed is preferable); if ultrasound unavailable, recommend C/S
- ECV and elective C/S should be presented as options with the risks and benefits outlined; obtain informed consent

Figure 5. Types of breech presentation

Criteria for Vaginal Breech Delivery

- Frank or complete breech, GA >36 wk
- EFW 2,500-3,800 g based on clinical and U/S assessment (5.5-8.5 lb)
- Fetal head flexed
- Continuous fetal monitoring
- 2 experienced obstetricians, assistant, and anesthetist present
- Ability to perform emergency C/S within 30 min if required

- method for vaginal breech delivery
 - encourage effective maternal pushing efforts
 - at delivery of head (after feet), assistant must apply suprapubic pressure to flex and engage fetal head
 - delivery can be spontaneous or assisted; avoid fetal traction
 - apply fetal manipulation only after spontaneous delivery to level of umbilicus
- C/S recommended if: the breech has not descended to the perineum in the second stage of labour after 2 h, in the absence of active pushing, or if vaginal delivery is not imminent after 1 h of active pushing
- contraindications to vaginal breech delivery
 - cord presentation
 - clinically inadequate maternal pelvis
 - fetal factors incompatible with vaginal delivery (e.g. hydrocephalus, macrosomia, fetal growth restriction)

Prognosis

- regardless of route of delivery, breech infants have lower birth weights and higher rates of perinatal mortality, congenital anomalies, abruption, and cord prolapse

Hypertensive Disorders of Pregnancy

Hypertension in Pregnancy

- hypertensive disorders of pregnancy are classified as either pre-existing or gestational HTN

PRE-EXISTING HYPERTENSION

Definition

- BP >140/90 prior to 20 wk GA, persisting >7 wk postpartum
- essential HTN is associated with an increased risk of gestational HTN, abruptio placentae, IUGR, and IUFD

GESTATIONAL HTN

Definition

- sBP >140 or dBP >90 developing after 20th wk GA in the absence of proteinuria in a woman known to be normotensive before pregnancy

Risk Factors

- maternal factors
 - primigravida (80-90% of gestational HTN), first conception with a new partner, PMHx or FHx of gestational HTN
 - DM, chronic HTN, or renal insufficiency
 - obesity
 - antiphospholipid syndrome
 - extremes of maternal age (<18 or >35 yr)
 - previous stillbirth or IUFD
- fetal factors
 - IUGR or oligohydramnios
 - GTN
 - multiple gestation
 - fetal hydrops “mirror syndrome”

Clinical Evaluation of HTN in Pregnancy

- in general, clinical evaluation should include the mother and fetus
- evaluation of mother
 - body weight
 - central nervous system
 - ◆ presence and severity of headache
 - ◆ visual disturbances – blurring, scotomata
 - ◆ tremulousness, irritability, somnolence
 - ◆ hyperreflexia
 - hematologic
 - ◆ bleeding, petechiae
 - hepatic
 - ◆ RUQ or epigastric pain
 - ◆ severe N/V
 - renal
 - ◆ urine output and colour
 - non-dependent edema (i.e. hands and face)

Vaginal Delivery of Breech Presentation

SOGC Clinical Practice Guidelines 2009;226:557-566.

Objective: To discuss risks and benefits of trial of labour versus planned C/S, with selection criteria, management, and delivery techniques for trial of vaginal breech birth.

Evidence: Randomized trials, prospective cohort studies and select cohort studies from Medline search for long-term outcomes and epidemiology of vaginal breech delivery.

Summary: Higher risk of perinatal mortality and short-term neonatal morbidity can be associated with vaginal breech birth as compared to elective C/S. However, careful case selection (including term singleton breech fetuses and clinically adequate maternal pelvis) and labour management may achieve a similar safety level as elective C/S (~2 per 1,000 births perinatal mortality, ~2% short-term neonatal morbidity). Specific protocols for vaginal breech delivery should be followed: continuous fetal heart monitoring, assessment for adequate progress in labour, no induction of labour recommended, emergency C/S available if required, and health care providers with requisite skills and experience. Informed consent for the preferred delivery method should be obtained.

Ominous Symptoms of HTN in Pregnancy

RUQ pain, headache, and visual disturbances

Hypertension in Pregnancy

Adverse Maternal Conditions

- sBP >160 mmHg
- dBP >100 mmHg
- HELLP
- Cerebral hemorrhage
- Renal dysfunction: oliguria <500 mL/d
- Left ventricular failure, pulmonary edema
- Placental abruption, DIC
- Symptoms
- Abdominal pain, N/V
- Headaches, visual problems
- SOB, chest pain
- Eclampsia: convulsions

Adverse Fetal Conditions

- IUGR
- Oligohydramnios
- Absent/reversed umbilical artery end diastolic flow
- Can result in:
 - Fetal disability and/or death

- **evaluation of fetus**
 - fetal movement
 - fetal heart rate tracing – NST
 - ultrasound for growth
 - BPP
 - Doppler flow studies

Laboratory Evaluation of Gestational Hypertension

- CBC
- PTT, INR, fibrinogen – if abnormal LFTs or bleeding
- ALT, AST
- creatinine, uric acid
- 24 h urine collection for protein or albumin:creatinine ratio

Complications

- maternal
 - liver and renal dysfunction
 - seizure “eclampsia”
 - abruptio placentae
 - left ventricular failure/pulmonary edema
 - DIC (release of placental thromboplastin consumptive coagulopathy)
 - HELLP syndrome
 - hemorrhagic stroke (50% of deaths)
- fetal (2° to placental insufficiency)
 - IUGR, prematurity, abruptio placentae, IUFD

Management

- for non-severe HTN (149-159/90-105) target a BP of 130-155/80-105 in women without comorbidities or <140/90 in women with comorbidities
- for both pre-existing and gestational HTN, labetalol 100-400 mg PO bid-tid, nifedipine XL preparation 20-60 mg PO od, or α -methyldopa 250-500 mg PO bid-qid
- for severe HTN (BP>160/110), give one of:
 - labetalol 20 mg IV then 20-80 mg IV q30min (max 300 mg) (then switch to oral)
 - nifedipine 5-10 mg capsule q30min
 - ♦ hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5 to 10 mg/hr IV, to a maximum of 20 mg IV (or 30 mg IM)
- no ACEI, ARBs, diuretics, prazosin, or atenolol
- pre-existing HTN and gestational HTN without any deterioration can be followed until 37 wk, then decide to induce shortly thereafter

PREECLAMPSIA

Definition

- pre-existing or gestational HTN with new onset proteinuria or adverse conditions

Risk Factors

- nulliparity
- preeclampsia in a previous pregnancy
- age >40 yr or <18 yr
- FHx of preeclampsia
- chronic HTN
- chronic renal disease
- antiphospholipid antibody syndrome or inherited thrombophilia
- vascular or connective tissue disease
- DM (pre-gestational and gestational)
- obesity
- hydrops fetalis “mirror syndrome”
- unexplained fetal growth restriction
- abruptio placentae
- there is a potential for further deterioration to severe preeclampsia as defined above

Management

- depends on GA, possible threat of seizures
- if stable and no adverse factors, may admit and follow, \pm decide to deliver as approaching 34-36 wk (must weigh risks of fetal prematurity vs. risks of developing severe preeclampsia/eclampsia)
- for severe preeclampsia, stabilize and deliver
- if severe preeclampsia during labour, increase maternal monitoring: hourly input and output, urine dip q12h, hourly neurological vitals, and increase fetal monitoring (continuous FHR monitoring)
- antihypertensive therapy
 - labetalol 20 mg IV, then 20-80 mg IV q30min (max 300 mg) (then switch to oral)
 - nifedipine 5-10 mg capsule q30min
 - ♦ hydralazine 5 mg IV, repeat 5-10 mg IV q30min or 0.5 to 10 mg/hr IV, to a maximum of 20 mg IV (or 30 mg IM)

I-A Evidence-Recommendation Highlights of SOGC Clinical Practice Guidelines Diagnosis, Evaluation, and Management of the Hypertensive Disorders of Pregnancy

J Obstet Gynaecol Can 2014;36(5):416-438

- For BP measurement, Korotkoff phase V should be used to designate the dBp.
- Calcium supplementation (of at least 1 g/d, orally) is recommended for women with low dietary intake of calcium (<600 mg/d). (I-A)
- For preeclampsia prevention among increased risk women, low-dose Aspirin® (75-100 mg/d) is recommended until delivery.
- Umbilical artery Doppler velocimetry should be part of the antenatal fetal surveillance in preeclampsia.
- Initial antihypertensive therapy for severe HTN (sBP >160 or dBp \geq 110) should be with labetalol, nifedipine, or hydralazine.
- Initial antihypertensive therapy for non-severe HTN (BP 140-159/90-109 mmHg) should be with methyldopa, β -blockers, or calcium channel blockers.
- Antenatal corticosteroids for fetal lung maturation should be considered for all women with preeclampsia before 34 wk gestation.
- In a planned vaginal delivery with an unfavourable cervix, cervical ripening should be used.
- Oxytocin 5 units IV or 10 units IM should be used as part of the management during the third stage of labour, particularly in the presence of thrombocytopenia or coagulopathy.
- MgSO₄ is the recommended first-line treatment for eclampsia.
- MgSO₄ is the recommended eclampsia prophylaxis in severe preeclampsia.

Preeclampsia Investigations

- CBC
- AST, ALT
- INR and aPTT (if abn LFTs or bleeding)
- Cr
- Urine (24 h protein collection or albumin/creatinine ratio)
- Uric acid

- seizure prevention
 - MgSO₄
 - postpartum management
 - risk of seizure highest in first 24 h postpartum – continue MgSO₄ for 12-24 h after delivery
 - vitals q1h
 - consider HELLP syndrome
 - most return to a normotensive BP within 2 wk

ECLAMPSIA

Definition

- the occurrence of one or more generalized convulsions and/or coma in the setting of preeclampsia and in the absence of other neurologic conditions

Epidemiology

- an eclamptic seizure occurs in approximately 0.5% of mildly preeclamptic women and 2-3% of severely preeclamptic women

Risk Factors

- same as risk factors for preeclampsia

Clinical Manifestations

- eclampsia is a clinical diagnosis
- typically tonic-clonic and lasting 60-75 s
- symptoms that may occur before the seizure include persistent frontal or occipital headache, blurred vision, photophobia, right upper quadrant or epigastric pain, and altered mental status
- in up to one third of cases, there is no proteinuria or blood pressure <140/90 mmHg prior to the seizure
- in general, women with typical eclamptic seizures who do not have focal neurologic deficits or prolonged coma do not require diagnostic evaluation including imaging

Management

- ABCs
- roll patient into LLDP
- supplemental O₂ via face mask to treat hypoxemia due to hypoventilation during convulsive episode
- aggressive antihypertensive therapy for sustained diastolic pressures ≥105 mmHg or systolic blood pressures ≥160 mmHg with hydralazine or labetalol
- prevention of recurrent convulsions: to prevent further seizures and the possible complications of repeated seizure activity (e.g. rhabdomyolysis, metabolic acidosis, aspiration pneumonitis, etc.)
- MgSO₄ is now the drug of choice, with previously used agents including diazepam and phenytoin
- the definitive treatment of eclampsia is DELIVERY, irrespective of gestational age, to reduce the risk of maternal morbidity and mortality from complications of the disease
- mode of delivery is dependent on clinical situation and fetal-maternal condition

HELLP Syndrome

Hemolysis
Elevated Liver enzymes
Low Platelets

Note

Eclampsia prior to 20 wk of gestation is rare and should raise the possibility of an underlying molar pregnancy or antiphospholipid syndrome

Differential Diagnosis of Cause for Seizure in a Pregnant Woman

- Stroke
- Hypertensive disease (hypertensive encephalopathy, pheochromocytoma)
- Space-occupying lesion of the CNS
- Metabolic disorders (hypoglycemia, SIADH)
- Infection (meningitis, encephalitis)
- Thrombotic thrombocytopenic purpura or thrombophilia
- Idiopathic epilepsy
- Use of illicit drugs
- Cerebral vasculitis

Medical Complications of Pregnancy

Iron and Folate Deficiency Anemia

Table 14. Iron Deficiency and Folate Deficiency Anemia

	Iron Deficiency Anemia	Folate Deficiency Anemia
Etiology	See Hematology, H15	See Hematology, H25
Epidemiology	Responsible for 80% of causes of non-physiologic anemia during pregnancy	Incidence varies from 0.5-25% depending on region, population, diet
Clinical Features	See Hematology, H15	See Hematology, H25
Investigations	See Hematology, H15	See Hematology, H25
Management	Prevention (non-anemic): 30 mg elemental iron/d (met by most prenatal vitamins) Treatment (anemic): 30-120 mg elemental iron/d 325 mg ferrous fumarate = 106 mg elemental Fe ²⁺ ; 325 mg ferrous sulfate = 65 mg elemental Fe ²⁺ ; 325 mg ferrous gluconate = 36 mg elemental Fe ²⁺ Polysaccharide-Iron Complex = 150 mg elemental Fe/capsule	Prevention: 0.4-1 mg folic acid PO daily for 1-3 mo preconceptually and throughout T1, or 5 mg folic acid per day with past history of ONTD, DM, or antiepileptic medication use
Complications	Maternal: angina, CHF, infection, slower recuperation, preterm labour Fetal: decreased oxygen carrying capacity leading to fetal distress, IUGR, and low birth weight	Maternal: decreased blood volume, N/V, anorexia Fetal: neural tube defects in T1, low birth weight, prematurity
Notes	Mother needs 1 g of elemental iron per fetus; this amount exceeds normal stores + dietary intake Iron requirements increase during pregnancy due to fetal/placental growth (500 mg), increased maternal RBC mass (500 mg), and losses (200 mg) – more needed for multiple gestations	Minimum daily requirement is 0.4 mg Most often associated with iron deficiency anemia Folic acid is necessary for closure of neural tube during early fetal development (by day 28 of gestation)

Diabetes Mellitus

Epidemiology

- 2-4% of pregnancies are complicated by DM

Classification of Diabetes Mellitus

- type 1 and type 2 DM (see [Endocrinology, E7](#))
- GDM: onset of DM during pregnancy (usually tested for around 24-28 wk GA)

Etiology

- type 1 and type 2 DM
- GDM: anti-insulin factors produced by placenta and high maternal cortisol levels create increased peripheral insulin resistance → leading to GDM and/or exacerbating pre-existing DM

MANAGEMENT

A. TYPE 1 and TYPE 2 DM

Preconception

- pre-plan and refer to high-risk clinic
- optimize glycemic control
- counsel patient on potential risks and complications
- evaluate for diabetic retinopathy, neuropathy, CAD

Pregnancy

- if already on oral medication, generally switch to insulin therapy
 - continuing glyburide or metformin controversial
 - teratogenicity unknown for other oral anti-hyperglycemics
- tight glycemic control
 - insulin dosage may need to be adjusted in T2 due to increased demand and increased insulin resistance
- monitor as for normal pregnancy, plus initial 24 h urine protein and creatinine clearance, retinal exam, HbA1c
 - HbA1c: >140% of pre-pregnancy value associated with increased risk of spontaneous abortion and congenital malformations
- increased fetal surveillance (BPP, NST), consider fetal ECHO (if high Hgb A1c in first trimester or just prior to pregnancy) to look for cardiac abnormalities

Labour

- timing of delivery depends on fetal and maternal health and risk factors (i.e. must consider size of baby, lung maturity, maternal blood glucose, and blood pressure control)
- can wait for spontaneous labour if blood glucose well-controlled and BPP normal
- induce by 38-39 wk
- type of delivery
 - increased risk of cephalopelvic disproportion (CPD) and shoulder dystocia with babies >4,000 g (8.8 lbs)
 - consider elective C/S for predicted birthweight >4,500 g (9.9 lbs) (controversial)
- monitoring
 - during labour, monitor blood glucose q1h with patient on insulin and dextrose drip
 - aim for blood glucose between 3.5-6.5 mmol/L to reduce the risk of neonatal hypoglycemia

Postpartum

- insulin requirements dramatically drop with expulsion of placenta (source of insulin antagonists)
- no insulin is required for 48-72 h postpartum in most type 1 DM
- monitor glucose q6h, restart insulin at two-thirds of pre-pregnancy dosage when glucose >8 mmol/L

B. GESTATIONAL DM

Screening and Diagnosis

- all pregnant women between 24-28 wk GA (or at any stage if high risk)
- 2 screening options
 - 1-step screening with fasting 75 g OGTT; GDM if ≥ 1 of:
 - ♦ FPG ≥ 5.1 mmol/L
 - ♦ 1h PG ≥ 10.0 mmol/L
 - ♦ 2h PG ≥ 8.5 mmol/L
 - 2-step screening (recommended by the Canadian Diabetes Association)
 - ♦ Step 1: Perform a random non-fasting 50 g OGCT
 - 1h PG < 7.8 mmol/L is normal
 - 1h PG ≥ 11.1 mmol/L is GDM
 - if 1h PG 7.8-11.0 mmol/L, proceed to Step 2
 - ♦ Step 2: Perform a fasting 75 g OGTT, GDM if ≥ 1 of:
 - FPG ≥ 5.3 mmol/L
 - 1h PG ≥ 10.6 mmol/L
 - 2h PG ≥ 9.0 mmol/L

Monitoring Glucose Levels

- Frequent measurements of blood glucose during pregnancy are advised for women with type 1 or 2 DM to help prevent or treat both hypoglycemia and hyperglycemia, and also improves neonatal outcome
- Aim for:
 - FPG ≤ 5.3 mmol/L (95 mg/dL)
 - 1 h post prandial PG ≤ 7.8 mmol/L (140 mg/dL), 2 h post prandial PG ≤ 6.7 mmol/L (120 mg/dL)
- Most women can be followed with monthly HbA1c determinations

Post-prandial blood glucose values seem to be the most effective at determining the likelihood of macrosomia or other adverse pregnancy outcomes

Risk Factors for GDM

- Age >25 yr
- Obesity
- Ethnicity (Aboriginal, Hispanic, Asian, African)
- FHx of DM
- Previous history of GDM
- Previous child with birthweight >4.0 kg
- Polycystic ovarian syndrome
- Current use of glucocorticoids
- Essential HTN or pregnancy-related HTN

Management

- first line is management through diet modification and increased physical activity
- initiate insulin therapy if glycemic targets not achieved within 2 wk of lifestyle modification alone
- glycemic targets: FPG <5.3 mmol/L, 1h PG <7.8 mmol/L, 2h PG <6.7 mmol/L
- oral agents can be used in pregnancy but is off-label and should be discussed with patient
- stop insulin and diabetic diet postpartum
- follow-up with 75 g OGTT by 3 months postpartum, counsel about lifestyle modifications, and perform glucose challenge test q3yr

Prognosis

- most maternal and fetal complications are related to hyperglycemia and its effects

Long-Term Maternal Complications

- type 1 and type 2 DM: risk of progressive retinopathy and nephropathy
- GDM: 50% risk of developing type 2 DM in next 20 yr

Table 15. Complications of DM in Pregnancy

Maternal	Fetal
<p>Obstetric HTN/preeclampsia (especially if pre-existing nephropathy/proteinuria): insulin resistance is implicated in etiology of HTN Polyhydramnios: maternal hyperglycemia leads to fetal hyperglycemia, which leads to fetal polyuria (a major source of amniotic fluid)</p>	<p>Growth Abnormalities Macrosomia: maternal hyperglycemia leads to fetal hyperinsulinism resulting in accelerated anabolism IUGR: due to placental vascular insufficiency</p>
<p>Diabetic Emergencies Hypoglycemia Ketoacidosis Diabetic coma</p>	<p>Delayed Organ Maturity Fetal lung immaturity: hyperglycemia interferes with surfactant synthesis (respiratory distress syndrome)</p>
<p>End-Organ Involvement or Deterioration (occur in type 1 DM and type 2 DM, not in GDM) Retinopathy Nephropathy</p>	<p>Congenital Anomalies (occur in type 1 DM and type 2 DM, not in GDM) 2-7x increased risk of cardiac (VSD), NTD, GU (cystic kidneys), GI (anal atresia), and MSK (sacral agenesis) anomalies due to hyperglycemia Note: Pregnancies complicated by GDM do not manifest an increased risk of congenital anomalies because GDM develops after the critical period of organogenesis (in T1)</p>
<p>Other Pyelonephritis/UTI: glucosuria provides a culture medium for <i>E. coli</i> and other bacteria Increased incidence of spontaneous abortion (in type 1 DM and type 2 DM, not in GDM): related to pre-conception glycemic control</p>	<p>Labour and Delivery Preterm labour/prematurity: most commonly in patients with HTN/preeclampsia Preterm labour is associated with poor glycemic control but the exact mechanism is unknown Increased incidence of stillbirth Birth trauma: due to macrosomia, can lead to difficult vaginal delivery and shoulder dystocia</p>
	<p>Neonatal Hypoglycemia: due to pancreatic hyperplasia and excess insulin secretion in the neonate Hyperbilirubinemia and jaundice: due to prematurity and polycythemia Hypocalcemia: exact pathophysiology not understood, may be related to functional hypoparathyroidism Polycythemia: hyperglycemia stimulates fetal erythropoietin production</p>

Group B Streptococcus

Epidemiology

- 15-40% vaginal carrier rate

Risk Factors (for neonatal disease)

- GBS bacteriuria during current pregnancy, even if treated
- previous infant with invasive GBS infection
- preterm labour <37 wk
- ruptured membranes >18 h before delivery
- intrapartum maternal temperature $\geq 38^{\circ}\text{C}$
- positive GBS screen between 35-37 weeks GA in current pregnancy

Clinical Features

- not harmful to mother
- risk of vertical transmission (neonatal sepsis, meningitis or pneumonia, and death)

Indications for Intrapartum Antibiotic GBS Prophylaxis

- Centres for Disease Control and Prevention. Prevention of Perinatal Group B Streptococcal Disease. *MMWR* 2010;59(RR-10):14
- Previous infant with invasive GBS disease.
 - GBS bacteriuria during any trimester of the current pregnancy.
 - Positive GBS vaginal-rectal screening culture in late gestation during current pregnancy.
 - Unknown GBS status at the onset of labour (culture not done, incomplete, or results unknown) and any of the following:
 - Delivery at <37 wk gestation
 - Amniotic membrane rupture ≥ 18 h
 - Intrapartum temperature $\geq 38.0^{\circ}\text{C}$ ($\geq 100.4^{\circ}\text{F}$)
 - Intrapartum nucleic-acid amplification test positive for GBS

Investigations

- offer screening to all women at 35-37 wk with vaginal and anorectal swabs for GBS culture

Treatment

- treatment of maternal GBS at delivery decreases neonatal morbidity and mortality
- indications for antibiotic prophylaxis: positive GBS screen, GBS in urine, or previous infant with GBS disease or GBS status unknown and one of the other risk factors
- antibiotics for GBS prophylaxis
 - penicillin G 5 million units IV, then 2.5 million units IV q4h until delivery
 - penicillin allergic but not at risk for anaphylaxis: cefazolin 2 g IV then 1 g q8h
 - penicillin allergic and at risk for anaphylaxis: vancomycin 1 g IV q12h until delivery
- if fever, broad spectrum antibiotic coverage is advised

Urinary Tract Infection

Treat asymptomatic bacteriuria in pregnancy because of increased risk of progression to cystitis, pyelonephritis, and probable increased risk of preterm labour

Epidemiology

- most common medical complication of pregnancy
- asymptomatic bacteriuria in 2-7% of pregnant women, more frequently in multiparous women
- note: asymptomatic bacteriuria should be treated in pregnancy due to increased risk of pyelonephritis and preterm labour

Etiology

- increased urinary stasis from mechanical and hormonal (progesterone) factors
- organisms include GBS as well as those that occur in non-pregnant women

Clinical Features

- may be asymptomatic
- dysuria, urgency, and frequency in cystitis
- fever, flank pain, and costovertebral angle tenderness in pyelonephritis

Investigations

- urinalysis, urine C&S
- cystoscopy and renal function tests in recurrent infections

Management

- uncomplicated UTI
 - first line: amoxicillin (250-500 mg PO q8h x 7 d)
 - alternatives: nitrofurantoin (100 mg PO bid x 7 d)
 - follow with monthly urine cultures
- pyelonephritis
 - hospitalization and IV antibiotics

Prognosis

- complications if untreated: acute cystitis, pyelonephritis, and possible preterm labour
- recurrence is common

Infections During Pregnancy

Table 16. Infections During Pregnancy

Infection	Agent	Source of Transmission	Greatest Transmission Risk to Fetus	Effects on Fetus	Effects on Mother	Diagnosis	Management
Chicken Pox	Varicella zoster virus (herpes family)	To mom: direct, respiratory To baby: transplacental	13-30 wk GA, and 5 d pre- to 2 d post-delivery	Congenital varicella syndrome (limb aplasia, chorioretinitis, cataracts, cutaneous scars, cortical atrophy, IUGR, hydrops), preterm labour	Fever, malaise, vesicular pruritic lesions	Clinical, ± vesicle fluid culture, ± serology	VZIG for mother if exposed, decreases congenital varicella syndrome Note: do not administer vaccine during pregnancy (live attenuated vaccine)
*CMV	DNA virus (herpes family)	To mom: blood/organ transfusion, sexual contact To baby: transplacental, during delivery, breast milk	T1-T3	5-10% develop CNS involvement (mental retardation, cerebral calcification, hydrocephalus, microcephaly, deafness, chorioretinitis)	Asymptomatic or flu-like	Serologic screen; isolate virus from urine or secretion culture	No specific treatment; maintain good hygiene and avoid high risk situations
Erythema Infectiosum (Fifth Disease)	Parvovirus B19	To mom: respiratory, infected blood products To baby: transplacental	10-20 wk GA	Spontaneous abortion (SA), stillbirth, hydrops <i>in utero</i>	Flu-like, rash, arthritis; often asymptomatic	Serology, viral PCR, maternal AFP; if IgM present, follow fetus with U/S for hydrops	If hydrops occurs, consider fetal transfusion
Hepatitis B	DNA virus	To mom: blood, saliva, semen, vaginal secretions To baby: transplacental, breast milk	T3 10% vertical transmission if asymptomatic and HBsAg +ve; 85-90% if HBsAg and HBeAg +ve	Prematurity, low birth weight, neonatal death	Fever, N/V, fatigue, jaundice, elevated liver enzymes	Serologic screening for all pregnancies	Rx neonate with HBIG and vaccine (at birth, 1, 6 mo); 90% effective
*Herpes Simplex Virus	DNA virus	To mom: intimate mucocutaneous contact To baby: transplacental, during delivery	Delivery (if genital lesions present); less commonly <i>in utero</i>	Disseminated herpes (20%); CNS sequelae (35%); self-limited infection	Painful vesicular lesions	Clinical diagnosis	Acyclovir for symptomatic women, suppressive therapy at 36 wk controversial Suggested C/S if active genital lesions, even if remote from vulva
HIV	RNA retrovirus	To mom: blood, semen, vaginal secretions To baby: in utero, during delivery, breast milk	1/3 <i>in utero</i> , 1/3 at delivery, 1/3 breastfeeding	IUGR, preterm labour, PROM	See Infectious Diseases, ID27	Serology, viral PCR All pregnant women are offered screening	Triple anti-retroviral therapy decreases transmission to <1% Elective C/S: no previous antiviral Rx or monotherapy only, viral load unknown or >500 RNA copies/mL, unknown prenatal care, patient request
*Rubella	ssRNA togavirus	To mom: respiratory droplets (highly contagious) To baby: transplacental	T1	SA or congenital rubella syndrome (hearing loss, cataracts, CV lesions, MR, IUGR, hepatitis, CNS defects, osseous changes)	Rash (50%), fever, posterior auricular or occipital lymphadenopathy, arthralgia	Serologic testing; all pregnant women screened (immune if titre >1:16); infection if IgM present or >4x increase in IgG	No specific treatment; offer vaccine following pregnancy Do not administer during pregnancy (live attenuated)
Syphilis	Spirochete (<i>Treponema pallidum</i>)	To mom: sexual contact To baby: transplacental	T1-T3	Risk of preterm labour, multisystem involvement, fetal death	See Infectious Diseases, ID25	VDRL screening for all pregnancies; if positive, requires confirmatory testing	Pen G 2.4 million U IM x 1 dose if early syphilis, 3 doses if late syphilis, monitor VDRL monthly If Pen G allergic: Clindamycin 900 mg IV q8h
*Toxoplasmosis	Protozoa (<i>Toxoplasma gondii</i>)	To mom: raw meat, unpasteurized goat's milk, cat feces/urine To baby: transplacental	T3 (but most severe if infected in T1); only concern if primary infection during pregnancy	Congenital toxoplasmosis (chorioretinitis, hydrocephaly, intracranial calcification, MR, microcephaly) NB: 75% initially asymptomatic at birth	Majority subclinical; may have flu-like symptoms	IgM and IgG serology; PCR of amniotic fluid	Self-limiting in mother; spiramycin decreases fetal morbidity but not rate of transmission

* Indicates TORCH infection

Venous Thromboembolism

Epidemiology

- incidence of 12.1/10,000 (DVT), and 5.4/10,000 (PE)
- increased risk of VTE throughout pregnancy with highest risk of DVT in third trimester and post-partum period; highest risk of PE post-partum (first 6 weeks)

Risk Factors

- previous VTE, age >35, obesity, infection, bedrest/immobility, shock/dehydration, thrombophilias (see [Hematology, H35](#))

Table 17. Risk Factors for VTE Specific to Pregnancy

Hypercoagulability	Stasis	Endothelial
II, V, VII, VIII, IX, X, XII, fibrinogen Increased platelet aggregation Decreased protein S, tPA, factors XI, XIII	Increased Factors Increased resistance to activated protein C Antithrombin can be normal or reduced Increased venous distensibility Decreased venous tone 50% decrease in venous flow in lower extremity by T3 Uterus is mechanical impediment to venous return	Vascular damage at delivery (C/S or SVD) Uterine instrumentation Peripartum pelvic surgery

Clinical Features

- most DVTs occur in the iliofemoral or calf veins with a predilection for the left leg
- signs of a pulmonary embolism are non-specific (as in non-pregnant women)
- unexplained spontaneous fetal loss

Investigations

- duplex venous Doppler sonography for DVT
- CXR and V/Q scan or spiral CT for PE

Management

- before initiating treatment, obtain a baseline CBC including platelets and aPTT
- warfarin is contraindicated during pregnancy due to its potential teratogenic effects
- unfractionated heparin
 - bolus of 5,000 IU followed by an infusion of ~30,000 IU/24h
 - measure aPTT 6 h after the bolus
 - maintain aPTT at a therapeutic level (1.5-2x normal)
 - repeat q24h once therapeutic
 - heparin-induced thrombocytopenia (HIT) uncommon (3%), but serious complication
 - LMWH can also be used in pregnancy
- compression stockings
- poor evidence to support a recommendation for or against avoidance of prolonged sitting
- VTE prophylaxis
 - women on long-term anticoagulation: full therapeutic anticoagulation throughout pregnancy and for 6-12 wk postpartum
 - women with a non-active PMHx of VTE: unfractionated heparin regimens suggested
 - insufficient evidence in pregnancy to recommend routine use of LMWH for all patients
 - current prophylaxis regimens for acquired thrombophilias (e.g. APS syndrome) include low dose Aspirin® in conjunction with prophylactic heparin

Virchow's Triad for VTE

- Hypercoagulable state
- Stasis
- Endothelial damage

Normal Labour and Delivery

Definition of Labour

- true labour: regular, painful contractions of increasing intensity associated with progressive dilatation and effacement of cervix and descent of presenting part, or progression of station
 - preterm (>20 to <36+6 wk GA)
 - term (37-41+6 wk GA)
 - postterm (>42 wk GA)
- false labour (Braxton-Hicks contractions): irregular contractions, with unchanged intensity and long intervals, occur throughout pregnancy and not associated with any cervical dilatation, effacement, or descent
 - often relieved by rest or sedation

The Cervix

- dilatation: latent phase (0-4 cm, variable time); active phase (4-10 cm)
- effacement: thinning of the cervix by percentage or length of cervix (cm)
- consistency: firm vs. soft
- position: posterior, mid, or anterior
- application: contact between the cervix and presenting part (i.e. well or poorly applied)
- see Bishop Score (Table 22, OB36)

The Fetus

- **fetal lie:** orientation of the long axis of the fetus with respect to the long axis of the uterus (longitudinal, transverse, oblique)
- **fetal presentation:** fetal body part closest to the birth canal
 - breech (complete, frank, incomplete) (see Figure 5, OB22)
 - cephalic (vertex/occiput, face, asynclitic, brow)
 - transverse (shoulder)
 - compound (fetal extremity prolapses along with presenting part)
 - all except vertex are considered malpresentations (see Obstetrical Complications, OB15)
- **fetal position:** position of presenting part of the fetus relative to the maternal pelvis
 - OA: most common presentation ("normal") – left OA most common
 - OP: most rotate spontaneously to OA; may cause prolonged second stage of labour
 - OT: leads to arrest of dilatation
 - ♦ normally, fetal head enters maternal pelvis and engages in OT position
 - ♦ subsequently rotates to OA position (or OP in a small percentage of cases)
- **attitude:** flexion/extension of fetal head relative to shoulders
 - brow presentation: head partially extended (requires C/S)
 - face presentation: head fully extended
 - ♦ mentum posterior always requires C/S, mentum anterior can deliver vaginally
- **station:** position of presenting bony part relative to ischial spines – determined by vaginal exam
 - at ischial spines = station 0 = engaged
 - -5 to -1 cm above ischial spines or
 - +1 to +5 cm below ischial spines

Maternal Triage Assessment

ID: Age, GPA, EDC, GA, GBS, Rh, Ser

CC

HPI: 4 key questions:

- Contractions: Since when, how close (q x min), how long (x s), how painful
- Bleeding: Since when, how much (pads), colour (pink mucous=show vs. brownish vs. bright red ± clots), pain?, last U/S, trauma/intercourse?
- Fluid (ROM): Since when, large gush vs. trickle, soaked pants?, clear vs. green vs. red?, continuous?
- FM: As much as usual?, When last movement?, Kick counts (lie still for 1-2 h, cold juice, feel FM – should have 6 movements in 2 h)

PregHx: Any complications (HTN, GDM, infections), IPS/FTS screening, last U/S (BPP score, growth/estimated fetal weight, position), last vaginal exam

POBHx: Every previous pregnancy and outcome: Year, SVD/CS/miscarriage/abortion, baby size, length of labour, use of vacuum or forceps, complications

PMHx, Meds, Allergies, SHx

O/E: Maternal vitals, fetal heart tracing (baseline, variability, presence of accelerations/decelerations), Leopold's, vaginal exam, U/S

Reference Point for Describing Fetal Position

- Occiput for cephalic presentation
- Sacrum for breech presentation
- Mentum for face presentation

Figure 6. Fetal positions

Four Stages of Labour

First Stage of Labour (0 – 10 cm cervical dilation)

- latent phase
 - uterine contractions typically infrequent and irregular
 - slow cervical dilatation (usually to 4 cm) and effacement
- active phase
 - rapid cervical dilatation to full dilatation (nulliparous ≥ 1.0 cm/h, multiparous ≥ 1.2 cm/h)
 - phase of maximum slope on cervical dilatation curve
 - painful, regular contractions q2-3min, lasting 45-60 s
 - contractions strongest at fundus

Second Stage of Labour (10 cm dilation – delivery of the baby)

- from full dilatation to delivery of the baby; duration varies based on parity, contraction quality, and type of analgesia
- mother feels a desire to bear down and push with each contraction
- women may choose a comfortable position that enhances pushing efforts and delivery
 - upright (semi-sitting, squatting) and LLDP are supported in the literature
- progress measured by descent

Third Stage of Labour (delivery of the baby – delivery of the placenta)

- from baby's birth to separation and expulsion of the placenta
- can last up to 30 min before intervention is indicated
- demonstrated by gush of fresh blood, umbilical cord lengthening, uterine fundus changing shape (firm and globular) and rising upward
- active management: start oxytocin IV drip, or give 10 U IM or 5 mg IV push after delivery of anterior shoulder in anticipation of placental delivery, otherwise give after delivery of placenta
- routine oxytocin administration in third stage of labour can reduce the risk of PPH by $>40\%$

Fourth Stage of Labour

- first postpartum hour
- monitor vital signs and bleeding, repair lacerations
- ensure uterus is contracted (palpate uterus and monitor uterine bleeding)
- inspect placenta for completeness and umbilical cord for presence of 2 arteries and 1 vein
- 3rd and 4th stages of labour most dangerous to the mother (i.e. hemorrhage)

Course of Normal Labour*

Stage	Nulliparous	Multiparous
First	6-18 h	2-10 h
Second	30 min-3 h	5-30 min
Third	5-30 min	5-30 min

*without epidural

Signs of Placental Separation

- Gush of blood
- Lengthening of cord
- Uterus becomes globular
- Fundus rises

Continuous Support for Women During Childbirth

Cochrane DB Syst Rev 2011;16:CD003766

Study: Systematic review of 21 RCTs from 11 countries, 15,061 women in labour.

Intervention: Continuous support during labour vs. usual care.

Outcome: Effects on mothers and their babies.

Results: Continuous intrapartum support increased likelihood of shorter labour, spontaneous vaginal birth, decrease in analgesia use, and a decrease in dissatisfaction with childbirth experience.

Greatest benefit when provider is not a health care professional. Continuous support was also associated with decreased likelihood to have a Cesarean or instrumental vaginal birth, regional analgesia, or a baby with a low 5 min APGAR score.

The Cardinal Movements of the Fetus During Delivery

Figure 7. Cardinal movements of fetus during delivery

Adapted from illustration in Williams Obstetrics, 19th ed

Analgesic and Anesthetic Techniques in Labour and Birth

- pain or anxiety leads to high endogenous catecholamines, which produce a direct inhibitory effect on uterine contractility

Non-Pharmacologic Pain Relief Techniques

- reduction of painful stimuli
 - maternal movement, position change, counter-pressure, abdominal compression
- activation of peripheral sensory receptors
 - superficial heat and cold
 - immersion in water during labour
 - touch and massage, acupuncture, and acupressure
 - TENS
 - intradermal injection of sterile water
 - aromatherapy
- enhancement of descending inhibitory pathways
 - attention focusing and distraction
 - hypnosis
 - music and audio analgesia
 - biofeedback

Pharmacologic Methods (see [Anesthesia and Perioperative Medicine, A26](#))

- nitrous oxide (e.g. self-administered Entonox®)
- narcotics (usually combined with anti-emetic)
- pudendal nerve block
- perineal infiltration with local anesthetic
- regional anesthesia (epidural block, combined spinal-epidural, spinal)

Fetal Monitoring in Labour

- see online [Fetal Heart Rate Tutorial](#)

Vaginal Exam

- membrane status, as indicated by amniotic fluid (clear, pink, bloody, meconium)
- cervical effacement (thinning), dilatation, consistency, position, application
- fetal presenting part, position, station
- bony pelvis size and shape
- monitor progress of labour at regular intervals and document in a partogram

Intrapartum Fetal Monitoring

- intermittent fetal auscultation with Doppler device q15-30min for 1 min in first stage active phase following a contraction, q5min during second stage when pushing has begun
- continuous electronic FHR monitoring reserved for abnormal auscultation, prolonged labour, labour which is induced or augmented, meconium present, multiple gestation/fetal complication
 - use of continuous electronic monitoring shown to lead to higher intervention rates and no improvement in outcome for the neonate when used routinely in all patients (i.e. no risk factors)
 - techniques for continuous monitoring include external (Doppler) vs. internal (fetal scalp electrode) monitoring
- fetal scalp sampling should be used in conjunction with electronic FHR monitoring and contraction monitoring (CTG) to resolve the interpretation of abnormal or atypical patterns

Electronic FHR Monitoring

- FHR measured by Doppler; contractions measured by tocometer
- described in terms of baseline FHR, variability (short-term, long-term), and periodicity (accelerations, decelerations)
- **Baseline FHR**
 - normal range is 110-160 bpm
 - parameter of fetal well-being vs. distress
- **Variability**
 - physiologic variability is a normal characteristic of FHR
 - variability is measured over a 15 min period and is described as: absent, minimal (<6 bpm), moderate (6-25 bpm), marked (>25 bpm)
 - normal variability indicates fetal acid-base status is acceptable
 - can only be assessed by electronic fetal monitoring (CTG)
 - variability decreases intermittently even in healthy fetus
 - see [Table 19, OB34](#)

Approach to the Management of Abnormal FHR

POISON – ER

- Position (left lateral decubitus position)
- O₂ (100% by mask)
- IV fluids (corrects maternal hypotension)
- Fetal scalp stimulation
- Fetal scalp electrode
- Fetal scalp pH
- Stop oxytocin
- Notify MD
- Vaginal exam to rule out cord prolapse
- Rule out fever, dehydration, drug effects, prematurity
- If above fails, consider C/S

Periodicity

- accelerations: increase of ≥ 15 bpm for ≥ 15 s, in response to fetal movement or uterine contraction (or ≥ 10 bpm for ≥ 10 s if < 32 wk GA)
- decelerations: 3 types, described in terms of shape, onset, depth, duration recovery, occurrence, and impact on baseline FHR and variability

Table 18. Factors Affecting Fetal Heart Rate

	Fetal Tachycardia (FHR > 160 bpm)	Fetal Bradycardia (FHR < 110 bpm)	Decreased Variability
Maternal Factors	Fever, hyperthyroidism, anemia, dehydration	Hypothermia, hypotension, hypoglycemia, position, umbilical cord occlusion	Infection Dehydration
Fetal Factors	Arrhythmia, anemia, infection, prolonged activity, chronic hypoxemia, congenital anomalies	Rapid descent, dysrhythmia, heart block, hypoxia, vagal stimulation (head compression), hypothermia, acidosis	CNS anomalies Dysrhythmia Inactivity/sleep cycle, preterm fetus
Drugs	Sympathomimetics	β -blockers Anesthetics	Narcotics, sedatives Magnesium sulphate, β -blockers
Uteroplacental	Early hypoxia (abruption, HTN) Chorioamnionitis	Late hypoxia (abruption, HTN) Acute cord prolapse Hypercontractility	Hypoxia

Table 19. Comparison of Decelerations

Early Decelerations	BPM	Early Deceleration
<ul style="list-style-type: none"> Uniform shape with onset early in contraction, returns to baseline by end of contraction, mirrors contraction (nadir occurs at peak of contraction) Gradual deceleration and return to baseline Often repetitive; no effect on baseline FHR or variability Benign, due to vagal response to head compression 		
<ul style="list-style-type: none"> Variable in shape, onset, and duration Most common type of periodicity seen during labour Often with abrupt drop in FHR > 15 bpm below baseline (> 15 s, < 2 min); usually no effect on baseline FHR or variability Due to cord compression or, in second stage, forceful pushing with contractions 		
<p>Complicated Variable Decelerations</p> <ul style="list-style-type: none"> FHR drop < 70 bpm for > 60 s Loss of variability or decrease in baseline after deceleration Biphasic deceleration Slow return to baseline Baseline tachycardia or bradycardia May be associated with fetal acidemia 		

Continuous CTG as a Form of EFM for Fetal Assessment During Labour
Cochrane DB Syst Rev 2013;5:CD006066
Purpose: To examine the effectiveness of continuous electronic fetal monitoring or cardiotocography during labour.
Selection Criteria: Randomized and quasi-randomized controlled trials comparing continuous CTG (with and without fetal blood sampling) to a) fetal monitoring, b) intermittent auscultation, or c) intermittent CTG.
Results: 13 trials, 37,000 women. Continuous CTG compared with intermittent auscultation showed no difference in overall perinatal death rate or cerebral palsy rates. Nonetheless, neonatal seizures were halved (RR 0.50, 95% CI 0.31-0.80) and there was a significant increase in Cesarean sections (RR 1.63, 95% CI 1.29-2.07) and instrumental vaginal birth (RR 1.15, 95% CI 1.01-1.33) with CTG.
Conclusion: Continuous CTG may reduce the incidence of neonatal seizures, but has no effect on cerebral palsy rates, infant mortality, or other measures of neonatal well-being. Continuous CTG was also associated with an increase in Cesarean sections and instrumental deliveries.

Rule of 60s Suggesting Severe Variable Decelerations
 Deceleration to < 60 bpm
 > 60 bpm below baseline
 > 60 s in duration with slow return to baseline

Table 20. Classification of Intrapartum EFM Tracings

	Normal Tracing (Category 1)	Atypical Tracing* (Category 2)	Abnormal Tracing* (Category 3)
Baseline	110-160 bpm	Bradycardia 100-110 bpm Tachycardia >160 for 30-80 min Rising baseline	Bradycardia <100 bpm Tachycardia >160 bpm for >80 min Erratic baseline
Variability	6-25 bpm ≤5 bpm for <40 min	≤5 bpm for 40-80 min	<5 bpm for >80 min ≥25 bpm for >10 min
Decelerations	None Early decelerations Occasional uncomplicated variable decelerations	Repetitive (≥3) uncomplicated variable decelerations Occasional late decelerations Any prolonged deceleration (2-3 min)	Repetitive (≥3) complicated variable decelerations Repetitive late decelerations Any prolonged deceleration (≥3 min)
Accelerations	Accelerations spontaneous or during scalp stimulation	Absent with scalp stimulation	Nearly absent
Action	EFM may be interrupted for ≤30 min if mother/fetus stable	Further assessment required	Action required: review clinical situation, obtain scalp pH, prepare for possible delivery

Adapted from SOGC Guidelines, September 2008

*Previous classification was "reassuring" vs. "non-reassuring", but distinction is now made between tracings that have some concerning changes but do not require immediate action (atypical) versus those with major concerns requiring immediate intervention (abnormal)

Fetal Scalp Blood Sampling

- cervix must be adequately dilated
- indicated when atypical or abnormal fetal heart rate is suggested by clinical parameters including heavy meconium or moderately to severely abnormal FHR patterns (including unexplained low variability, repetitive late decelerations, complex variable decelerations, fetal cardiac arrhythmias)
- done by measuring pH or more recently fetal lactate
 - pH ≥7.25, lactate <4.2 mmol/L: normal, repeat if abnormal FHR persists
 - pH 7.21-7.24, lactate 4.2-4.8 mmol/L: repeat assessment in 30 min or consider delivery if rapid fall since last sample
 - pH ≤7.20, lactate >4.8 mmol/L: indicates fetal acidosis, delivery is indicated
- contraindications
 - known or suspected fetal blood dyscrasia (hemophilia, von Willebrand disease)
 - active maternal infection (HIV, genital herpes)

Fetal Oxygenation

- uterine contractions during labour decrease uteroplacental blood flow, which results in reduced oxygen delivery to the fetus
- most fetuses tolerate this reduction in flow and have no adverse effects
- distribution of oxygen to the fetus depends on maternal, uteroplacental, and fetal factors
- fetal response to hypoxia/asphyxia:
 - decreased movement, tone, and breathing activities
 - anaerobic metabolism (decreased pH)
 - transient fetal bradycardia followed by fetal tachycardia
 - redistribution of fetal blood flow
 - ♦ increased flow to brain, heart, and adrenals
 - ♦ decreased flow to kidneys, lungs, gut, liver, and peripheral tissues
 - ♦ increase in blood pressure

Table 21. Factors Affecting Fetal Oxygenation

Factor	Mechanism	Example
Maternal	Decreased maternal oxygen carrying capacity	Significant anemia (iron deficiency, hemoglobinopathies), carboxyhemoglobin (smokers)
	Decreased uterine blood flow	Hypotension (blood loss, sepsis), regional anesthesia, maternal positioning
	Chronic maternal conditions	Vasculopathies (SLE, type 1 DM, chronic HTN), antiphospholipid syndrome, cyanotic heart disease, COPD
Uteroplacental	Uterine hypertonus	Placental abruption, hyperstimulation secondary to oxytocin, prostaglandins, or normal labour
	Uteroplacental dysfunction	Placental abruption, placental infarction (dysfunction marked by IUGR, oligohydramnios, abnormal Doppler studies), chorioamnionitis, placental edema (DM, hydrops), placental senescence (post-dates)
Fetal	Cord compression	Oligohydramnios, cord prolapse, or entanglement
	Decreased fetal oxygen carrying capacity	Significant anemia (isoimmunization, feto-maternal bleed), carboxyhemoglobin (exposure to smokers)

Induction of Labour

Definition

- artificial initiation of labour in a pregnant woman prior to spontaneous initiation to deliver the fetus and placenta

Prerequisites for Labour Induction

- capability for C/S if necessary
- maternal
 - inducible/ripe cervix: short, thin, soft, anterior cervix with open os
 - if cervix is not ripe, use prostaglandin vaginal insert (Cervidil®), prostaglandin gel (Prepidil®), misoprostol (Cytotec®), or Foley catheter
- fetal
 - normal fetal heart tracing
 - cephalic presentation
 - adequate fetal monitoring available
- likelihood of success determined by Bishop score
 - cervix considered unfavourable if <6
 - cervix favourable if ≥6
 - score of 9-13 associated with high likelihood of vaginal delivery

Table 22. Bishop Score

Cervical Characteristic	0	1	2	3
Position	Posterior	Mid	Anterior	–
Consistency	Firm	Medium	Soft	–
Effacement (%)	0-30	40-50	60-70	≥80
Dilatation (cm)	0	1-2	3-4	≥5
Station of Fetal Head	-3	-2	-1, 0	+1, +2, +3

Indications

- post-dates pregnancy (generally >41 wk) = most common reason for induction
- maternal factors
 - DM = second most common reason for induction
 - gestational HTN
 - other maternal medical problems, e.g. renal or lung disease, chronic hypertension, cholestasis
 - maternal age over 40
- maternal-fetal factors
 - isoimmunization, PROM, chorioamnionitis, post-term pregnancy
- fetal factors
 - suspected fetal jeopardy as evidenced by biochemical or biophysical indications
 - fetal demise, IUGR, oligo/polyhydramnios, anomalies requiring surgical intervention, twins
 - previous stillbirth, low PAPP-A

Risks

- failure to achieve labour and/or vaginal birth
- uterine hyperstimulation with fetal compromise or uterine rupture
- maternal side effects to medications
- uterine atony and PPH

Contraindications

- maternal
 - prior classical or inverted T-incision C/S or uterine surgery (e.g. myomectomy)
 - unstable maternal condition
 - active maternal genital herpes
 - invasive cervical carcinoma
 - pelvic structure deformities
- maternal-fetal
 - placenta previa or vasa previa
 - cord presentation
- fetal
 - fetal distress, malpresentation/abnormal lie, preterm fetus without lung maturity

Induction is indicated when the risk of continuing pregnancy exceeds the risks associated with induced labour and delivery

Induction vs. Augmentation
Induction is the artificial initiation of labour
Augmentation promotes contractions when spontaneous contractions are inadequate

Consider the Following Before Induction

- Indication for induction
- Contraindications
- GA
- Cervical favourability
- Fetal presentation
- Potential for CPD
- Fetal well-being/FHR
- Membrane status

Induction Methods

CERVICAL RIPENING

Definition

- use of medications or other means to soften, efface, and dilate the cervix; increases likelihood of successful induction
- ripening of an unfavourable cervix (Bishop score <6) is warranted prior to induction of labour

Methods

- intravaginal prostaglandin PGE2 gel (Prostin® gel): long and closed cervix
 - recommended dosing interval of prostaglandin gel is every 6-12 h up to 3 doses
- intravaginal PGE2 (Cervidil®): long and closed cervix, may use if ROM
 - continuous release, can be removed if needed
 - controlled release PGE2
- intravaginal PGE1 Misoprostol (Cytotec®): long and closed cervix
 - inexpensive, stored at room temperature
 - more commonly used in 2nd trimester termination of pregnancy
- Foley catheter placement to mechanically dilate the cervix

INDUCTION OF LABOUR

Amniotomy

- artificial rupture of membranes (amniotomy) to stimulate prostaglandin synthesis and secretion; may try this as initial measure if cervix is open and soft, the membranes can be felt, and if the head is present at the cervix
- few studies address the value of amniotomy alone for induction of labour
- amniotomy plus intravenous oxytocin: more women delivered vaginally at 24 h than amniotomy alone (relative risk = 0.03) and had fewer instrumental vaginal deliveries (relative risk = 5.5)

Oxytocin

- oxytocin (Pitocin®): 10 U in 1L NS, run at 0.5-2 mU/min IV increasing by 1-2 mU/min q20-60min to a max of 36-48 mU/min
- reduces rate of unsuccessful vaginal deliveries within 24 h when used alone (8.3% vs. 54%, RR 0.16)
- ideal dosing regimen of oxytocin is not known
- current recommendations: use the minimum dose to achieve active labour and increase q30min as needed
- reassessment should occur once a dose of 20 mU/min is reached
- potential complications
 - hyperstimulation/tetanic contraction (may cause fetal distress or rupture of uterus)
 - uterine muscle fatigue, uterine atony (may result in PPH)
 - vasopressin-like action causing anti-diuresis

Augmentation of Labour

- augmentation of labour is used to promote adequate contractions when spontaneous contractions are inadequate and cervical dilatation or descent of fetus fails to occur
- oxytocin

Abnormalities and Complications of Labour and Delivery

Abnormal Progression of Labour (Dystocia)

Definition

- expected patterns of descent of the presenting part and cervical dilatation fail to occur in the appropriate time frame; can occur in all stages of labour
- during active phase: >4 h of <0.5 cm/h
- during 2nd stage: >1 h with no descent during active pushing

Etiology

- Power (leading cause): contractions (hypotonic, uncoordinated), inadequate maternal expulsive efforts
- Passenger: fetal position, attitude, size, anomalies (hydrocephalus)
- Passage: pelvic structure (CPD), maternal soft tissue factors (tumours, full bladder or rectum, vaginal septum)
- Psyche: hormones released in response to stress may contribute to dystocia; psychological and physiological stress should be evaluated as part of the management once dystocia has been diagnosed

Evidence for Cervical Ripening Methods (SOGC Guidelines)

- Meta-analysis of five trials has concluded that the use of oxytocin to ripen the cervix is not effective
- Since the best dose and route of misoprostol for labour induction with a live fetus are not known and there are concerns regarding hyperstimulation, the use of misoprostol for induction of labour should be within clinical trials only (Level 1b evidence) or in cases of intrauterine fetal death to initiate labour

Intravaginal PGE2 (Cervidil®) Compared to Intravaginal Prostaglandin Gel

4 RCTs have compared the two with varying results, depending on the dosing regime of gel used.

Theoretical advantages of Cervidil®:

- Slow, continuous release
- Only one dose required
- Ability to use oxytocin 30 min after removal vs. 6 hours for gel
- Ability to remove insert if required (i.e. excessive uterine activity)

Oxytocin t1/2 = 3-5 min

Provided there are no contraindications, oxytocin is utilized to improve uterine contraction strength and/or frequency

The 4 Ps of Dystocia

Power
Passenger
Passage
Psyche

Management

- confirm diagnosis of labour (rule out false labour)
- search for factors of CPD
- diagnosed if adequate contractions measured by intrauterine pressure catheter (IUPC) with no descent/dilatation for >2 h
- management: if CPD ruled out, IV oxytocin augmentation ± amniotomy

Risks of Dystocia

- inadequate progression of labour is associated with an increased incidence of:
 - maternal stress
 - maternal infection
 - postpartum hemorrhage
 - need for neonatal resuscitation
 - fetal compromise (from uterine hyperstimulation)
 - uterine rupture
 - hypotension

Shoulder Dystocia

Definition

- fetal anterior shoulder impacted above symphysis pubis after fetal head has been delivered
- life threatening emergency

Etiology/Epidemiology

- incidence 0.15-1.4% of deliveries
- occurs when breadth of shoulders is greater than biparietal diameter of the head

Risk Factors

- maternal: obesity, DM, multiparity, previous shoulder dystocia
- fetal: prolonged gestation, macrosomia (especially if associated with GDM)
- labour
 - prolonged 2nd stage
 - instrumental midpelvic delivery

Presentation

- “turtle sign”: head delivered but retracts against inferior portion of pubic symphysis
- complications
 - fetal
 - ♦ hypoxic ischemic encephalopathy (chest compression by vagina or cord compression by pelvis can lead to hypoxia)
 - ♦ brachial plexus injury (Erb’s palsy: C5-C7; Klumpke’s palsy: C8-T1), 90% resolve within 6 mo
 - ♦ fracture (clavicle, humerus, cervical spine)
 - ♦ death
 - maternal
 - ♦ perineal injury
 - ♦ PPH (uterine atony, lacerations)
 - ♦ uterine rupture

Treatment

- goal: to displace anterior shoulder from behind symphysis pubis; follow a stepwise approach of maneuvers until goal achieved
- other options
 - cleidotomy (deliberate fracture of neonatal clavicle)
 - Zavanelli maneuver: replacement of fetus into uterine cavity and emergent C/S
 - symphysiotomy

Prognosis

- 1% risk of long-term disability for infant

Umbilical Cord Prolapse

Definition

- descent of the cord to a level adjacent to or below the presenting part, causing cord compression between presenting part and pelvis

Etiology/Epidemiology

- increased incidence with prematurity/PROM, fetal malpresentation (~50% of cases), low-lying placenta, polyhydramnios, multiple gestation, CPD
- incidence: 1/200-1/400 deliveries

Approach to the Management of Shoulder Dystocia

ALARME

Apply suprapubic pressure and ask for help
 Legs in full flexion (McRobert’s maneuver)
 Anterior shoulder disimpaction (suprapubic pressure)

Release posterior shoulder by rotating it anteriorly with hand in the vagina under adequate anesthesia

Manual corkscrew i.e. rotate the fetus by the posterior shoulder until the anterior shoulder emerges from behind the maternal symphysis

Episiotomy

Rollover (on hands and knees)

*Note that suprapubic pressure and McRobert’s maneuver together will resolve 90% of cases

Umbilical Cord Accident Causes

- Nuchal cord
 - Type A (looped)
 - Type B (hitched)
- Body loop
- Single artery
- True knot
- Torsion
- Velamentous
- Short cord <35 cm
- Long cord >80 cm

Presentation

- visible or palpable cord
- FHR changes (variable decelerations, bradycardia, or both)

Treatment

- emergency C/S
- O₂ to mother, monitor fetal heart
- alleviate pressure of the presenting part on the cord by elevating fetal head with a pelvic exam (maintain this position until C/S)
- keep cord warm and moist by replacing it into the vagina ± applying warm saline soaks
- roll mom onto all fours
- position mother in Trendelenburg or knee-to-chest position
- if fetal demise or too premature (<22 wk), allow labour and delivery

- 1/3 of protraction disorders develop into 2° arrest of dilatation due to CPD
- 2/3 of protraction disorders progress through labour to vaginal delivery

Uterine Rupture

Etiology/Epidemiology

- associated with previous uterine scar (in 40% of cases), hyperstimulation with oxytocin, grand multiparity, and previous intrauterine manipulation
- generally occurs during labour, but can occur earlier with a classical incision
- 0.5-0.8% incidence, up to 12% with classical incision

Presentation

- prolonged fetal bradycardia – most common presentation
- acute onset of constant lower abdominal pain, may not have pain if receiving epidural analgesia
- hyper/hypotonic uterine contractions
- vaginal bleeding
- intra-abdominal hemorrhage
- sudden loss of fetal descent

Risk Factors

- uterine scarring (i.e. previous uterine surgeries including Cesarean (especially classical incision), perforation with D&C, myomectomy)
- excessive uterine stimulation (i.e. protracted labour, oxytocin, prostaglandins)
- uterine trauma (i.e. operative equipment, ECV)
- multiparity
- uterine abnormalities
- placenta accreta

Treatment

- rule out placental abruption
- immediate delivery for fetal survival
- maternal stabilization (may require hysterectomy), treat hypovolemia

Complications

- maternal mortality 1-10%
- maternal hemorrhage, shock, DIC
- amniotic fluid embolus
- hysterectomy if uncontrollable hemorrhage
- fetal distress, associated with 50% fetal mortality

**Maternal Mortality Causes**

- Thromboembolism
- Cardiac event
- Suicide
- Sepsis
- Ectopic pregnancy
- HTN
- Amniotic fluid embolism
- Hemorrhage

* In Canada (2013), lifetime risk of maternal death is 1 in 5,200

Amniotic Fluid Embolus

Definition

- amniotic fluid debris in maternal circulation triggering an anaphylactoid immunologic response

Etiology/Epidemiology

- rare intrapartum or immediate postpartum complication
- 60-80% maternal mortality rate, accounts for 10% of all maternal deaths
- leading cause of maternal death in induced abortions and miscarriages
- 1/8,000-1/80,000 births

Risk Factors

- placental abruption
- rapid labour
- multiparity
- uterine rupture
- uterine manipulation

Differential Diagnosis

- pulmonary embolus, drug-induced anaphylaxis, septic shock, eclampsia, HELLP syndrome, abruption, chronic coagulopathy

Presentation

- sudden onset of respiratory distress, cardiovascular collapse (hypotension, hypoxia), and coagulopathy
- seizure in 10%
- ARDS and left ventricular dysfunction seen in survivors

Management

- supportive measures (high flow O₂, ventilation support, fluid resuscitation, inotropic support, ± intubation), coagulopathy correction
- ICU admission

Chorioamnionitis

Definition

- infection of the chorion, amnion, and amniotic fluid typically due to ascending infection by organisms of normal vaginal flora

Etiology/Epidemiology

- incidence 1-5% of term pregnancies and up to 25% in preterm deliveries
- ascending from vagina
- predominant microorganisms include: GBS, *Bacteroides* and *Prevotella* species, *E. coli*, and anaerobic *Streptococcus*

Risk Factors

- prolonged ROM, long labour, multiple vaginal exams during labour, internal monitoring
- bacterial vaginosis and other vaginal infections

Clinical Features

- maternal fever, maternal or fetal tachycardia, uterine tenderness, foul and purulent cervical discharge

Investigations

- CBC: leukocytosis
- amniotic fluid: leukocytes or bacteria

Treatment

- IV antibiotics
 - ampicillin 2 g IV q6h and gentamicin 1.5 mg/kg IV q8h
 - anaerobic coverage (i.e. clindamycin 900 mg IV q8h)
- expedient delivery regardless of gestational age

Complications

- bacteremia of mother or fetus, wound infection if C/S, pelvic abscess, infant meningitis

**Clinical Features of Chorioamnionitis**

- Temperature
- Tachycardia (maternal or fetal)
- Tenderness (uterine)
- Foul discharge

Meconium

Epidemiology

- present early in labour in 10% of pregnancies, more common in postdate pregnancies
- in general, meconium may be present in up to 25% of all labours; usually NOT associated with poor outcome, but extra care is required at time of delivery to avoid aspiration. Concern if fluid changes from clear to meconium-stained. Always abnormal if seen in preterm fetus

Etiology

- likely cord compression ± uterine hypertonia
- may indicate undiagnosed breech
- increasing meconium during labour may be a sign of fetal distress

Features

- may be watery or thicker (particulate)
- light yellow/green or dark green-black in colour

Treatment

- call respiratory therapy, neonatology, or pediatrics to delivery room
- closely monitor FHR for signs of fetal distress

Particulate (thickened) meconium is associated with lower APGARs, an increased risk of meconium aspiration, and perinatal death. Particulate meconium generally has a darker green or black colour, whereas thin meconium is usually yellow to light green

Operative Obstetrics

Operative Vaginal Delivery

Definition

- forceps or vacuum extraction

Indications

- fetal
 - atypical or abnormal fetal heart rate tracing, evidence of fetal compromise
 - consider if second stage is prolonged, as this may be due to poor contractions or failure of fetal head to rotate
- maternal
 - need to avoid voluntary expulsive effort (e.g. cardiac/cerebrovascular disease)
 - exhaustion, lack of cooperation, and excessive analgesia may impair pushing effort

Contraindications

- non-vertex cephalic presentation (i.e. brow or face)
- unengaged head
- cervix incompletely dilated

Forceps

Outlet Forceps Position

- head visible between labia in between contractions
- sagittal suture in or close to AP diameter
- rotation cannot exceed 45°

Low Forceps Position

- presenting part at station +2 or greater
- subdivided based on whether rotation less than or greater than 45 degrees

Mid Forceps Position

- presenting part below spines but above station +2

Types of Forceps

- Simpson or Tucker-McLane forceps for OA presentations
- Kielland (rotational) forceps when rotation of head is required
- Piper forceps for breech

Vacuum Extraction

- traction instrument used as alternative to forceps delivery; aids maternal pushing
- contraindications: <34 wk GA (<2500 g), fetal head deflexed, fetus requires rotation, fetal condition (e.g. bleeding disorder)

Table 23. Advantages and Disadvantages of Forceps versus Vacuum Extraction

	Forceps	Vacuum Extraction
Advantages	Higher overall success rate for vaginal delivery Decreased incidence of fetal morbidity	Easier to apply Less anesthesia required Less maternal soft-tissue injury compared to forceps
Disadvantages	Greater incidence of maternal injury	Contraindicated if fetus at risk for coagulation defect Suitable only for vertex presentations Maternal pushing required Contraindicated in preterm delivery
Complications	Maternal: anesthesia risk, lacerations, injury to bladder, uterus, or bone, pelvic nerve damage, PPH, infections Fetal: fractures, facial nerve palsy, trauma to face/scalp, intracerebral hemorrhage, cephalohematoma, cord compression	Increased incidence of cephalohematoma and retinal hemorrhages, and jaundice compared to forceps Subgaleal hemorrhage Subaponeurotic hemorrhage Soft tissue trauma

Prerequisites for Operative Vaginal Delivery

ABCDEFGHIJK

- Anesthesia (adequate)
- Bladder empty
- Cervix fully dilated and effaced with ROM
- Determine position of fetal head
- Equipment ready (including facilities for emergent C/S)
- Fontanelle (posterior fontanelle midway between thighs)
- Gentle traction
- Handle elevated
- Incision (episiotomy)
- Once jaw visible remove forceps
- Knowledgeable operator

A. Simpson forceps
B. Tucker-McLane forceps
C. Kielland forceps
D. Piper forceps

Figure 8. Types of forceps

Limits for Trial of Vacuum

- After 3 pulls over 3 contractions with no progress
- After 3 pop-offs with no obvious cause
- 20 min and delivery is not imminent

Lacerations

- first degree: involves skin and vaginal mucosa but not underlying fascia and muscle
- second degree: involves fascia and muscles of the perineal body but not the anal sphincter
- third degree: involves the anal sphincter (partial IIIa or complete IIIb)
- fourth degree: extends through the anal sphincter into the rectal mucosa

Episiotomy

Definition

- incision in the perineal body at the time of delivery
- essentially a controlled second degree laceration
- midline: incision through central tendinous portion of perineal body and insertions of superficial transverse perineal and bulbocavernosus muscle
 - heals better, but increases risk of 3rd/4th degree tears
- mediolateral: incision through bulbocavernosus, superficial transverse perineal muscle, and levator ani
 - reduced risk of extensive tear but more painful
 - easier to repair

Indications

- to relieve obstruction of the unyielding perineum
- to expedite delivery (e.g. abnormal FHR pattern)
- instrumental delivery
- controversial between practitioners as to whether it is preferable to make a cut or let the perineum tear as needed
- current evidence suggests letting perineum tear and then repair as needed (restricted use)

Complications

- infection, hematoma, extension into anal musculature or rectal mucosa, fistula formation, incontinence

Cesarean Delivery

Epidemiology

- incidence 20-25%

Indications

- maternal: obstruction, active herpetic lesion on vulva, invasive cervical cancer, previous uterine surgery (past C/S is most common), underlying maternal illness (eclampsia, HELLP syndrome, heart disease)
- maternal-fetal: failure to progress, placental abruption or previa, vasa previa
- fetal: abnormal fetal heart tracing, malpresentation, cord prolapse, certain congenital anomalies

Types of Cesarean Incisions

- skin
 - transverse (i.e. Pfannenstiel)
 - ♦ decreased exposure and slower entry
 - ♦ improved strength and cosmesis
 - vertical midline
 - ♦ rapid peritoneal entry and increased exposure
 - ♦ increased dehiscence
- uterine
 - low transverse (most common): in noncontractile lower segment
 - ♦ decreased chance for rupture in subsequent pregnancies
 - low vertical
 - ♦ used for very preterm infants, poorly developed maternal lower uterine segment
 - classical (rare): in thick, contractile segment
 - ♦ used for transverse lie, preterm breech, fetal anomaly, >2 fetuses, lower segment adhesions, obstructing fibroid, morbidly obese patients

Risks/Complications

- complications related to general anesthesia* (e.g. aspiration)
- hemorrhage (average blood loss ~1,000 cc)
- infection (UTI, wound, endometritis)
 - single dose prophylactic antibiotic should be used (e.g. cefazolin 1-2 g)
- injury to surrounding structures (bowel, bladder, ureter, uterus)
- thromboembolism (DVT, PE)
- increased recovery time/hospital stay
- maternal mortality (<0.1%)

Risk Factors for Primary and Subsequent Anal Sphincter Lacerations

Am J Obstet Gynecol 2007;196:344

Objective: Assess effects of pregnancy, delivery method, and parity on risk of primary and secondary anal sphincter laceration in women with 1st vaginal delivery (VD), VBAC, or 2nd VD.

Methods: Retrospective cohort study of all deliveries at one hospital from 1995-2002.

Conclusion: 20,674 live singleton deliveries were included. Women with first VD and VBAC both had OR 5.1 for laceration compared to 2nd VD. Forceps and midline episiotomy significantly increased risk of laceration for all 3 groups. Second stage of labour >2 h only increased risk for 1st VD. Factors that had no significant increase in risk: infant birth weight >3,500 g and vacuum delivery. Women with prior anal sphincter laceration are at 3x increased risk for subsequent sphincter laceration, compared with women with prior vaginal delivery without sphincter laceration.

Common OR Questions

7 Layers to Dissect

Skin, fatty layer, fascia, muscle separation (rectus abdominis), peritoneum, bladder flap, uterus

Layers of the Rectus Sheath

Above the arcuate line: external oblique, external/internal oblique, internal oblique, transversus abdominis, internal internal oblique, transversus abdominis

Below the arcuate line: external oblique, internal oblique, transversus abdominis, rectus abdominis

Name of the Obliterated Umbilical Ligament

- Urachus

Most C/S performed with regional analgesia

Trial of Labour after Cesarean Section (TOLAC)

- should be recommended if no contraindications after previous low transverse incision
- success rate varies with indication for previous C/S (generally 60-80%)
- risk of uterine rupture (<1% with low transverse incision), increased by interval <18 months and one layer closure

Contraindications

- previous classical, inverted T, or unknown uterine incision, or complete transection of uterus (6% risk of rupture)
- history of uterine surgery (e.g. myomectomy) or previous uterine rupture
- multiple gestation
- non-vertex presentation or placenta previa
- inadequate facilities or personnel for emergency C/S

VBAC*

- Rate of successful VBAC ranges from 60-82%
- No significant difference in maternal deaths or hysterectomies between VBAC or C/S
- Uterine rupture more common in VBAC group
- Evidence regarding fetal outcome is lacking

*Safety of vaginal birth after Cesarean section: A systematic review. *Obstet Gynecol* 2004;103:420-9

Puerperal Complications

- puerperium: 6 wk period of adjustment after pregnancy when pregnancy-induced anatomic and physiologic changes are reversed

Postpartum Hemorrhage

Definition

- loss of >500 mL of blood at the time of vaginal delivery, or >1,000 mL with C/S
- early (immediate) – within first 24 h postpartum
- late (delayed) – after 24 h but within first 6 wk

Epidemiology

- incidence 5-15%

Etiology (4 Ts)

1. **Tone** (uterine atony)
 - most common cause of PPH
 - avoid by giving oxytocin with delivery of the anterior shoulder or placenta occurs within first 24 h
 - due to:
 - ♦ overdistended uterus (polyhydramnios, multiple gestations, macrosomia)
 - ♦ uterine muscle exhaustion (prolonged or rapid labour, grand multiparity, oxytocin use, general anesthetic)
 - ♦ uterine distortion (fibroids, placenta previa, placental abruption)
 - ♦ intra-amniotic infection (fever, prolonged ROM)
2. **Tissue**
 - retained placental products (membranes, cotyledon or succenturiate lobe)
 - retained blood clots in an atonic uterus
 - gestational trophoblastic neoplasia
 - abnormal placentation
3. **Trauma**
 - laceration (vagina, cervix, uterus), episiotomy, hematoma (vaginal, vulvar, retroperitoneal), uterine rupture, uterine inversion
4. **Thrombin**
 - coagulopathy (pre-existing or acquired)
 - ♦ most identified prior to delivery (low platelets increases risk)
 - ♦ includes hemophilia, DIC, Aspirin® use, ITP, TTP, vWD (most common)
 - ♦ therapeutic anti-coagulation

Uterine atony is the most common cause of PPH

DDx of Early PPH – 4 Ts

Tone (atony)
Tissue (retained placenta, clots)
Trauma (laceration, inversion)
Thrombin (coagulopathy)

DDx of Late PPH

Retained products
± endometritis
Sub-involution of uterus

Investigations

- assess degree of blood loss and shock by clinical exam
- explore uterus and lower genital tract for evidence of tone, tissue, or trauma
- may be helpful to observe red-topped tube of blood – no clot in 7-10 min indicates coagulation problem

Management

- ABCs, call for help
- 2 large bore IVs, run crystalloids wide open
- CBC, coagulation profile, cross and type pRBCs
- treat underlying cause
- Foley catheter to empty bladder and monitor urine output

Medical Therapy

- oxytocin 5 U IV bolus (20-40 U/250 mL crystalloid) with delivery of anterior shoulder or infusion of 20 U in 1000 mL crystalloid at 50 mL/h or can give 10 U IM if CV collapse or IV access not possible
- methylergonavine maleate (ergotamine) 0.25 mg IM/IMM q15min up to 1.25 mg; can be given as IV bolus of 0.125 mg (may exacerbate HTN)
- carboprost (Hemabate®), a synthetic PGF-1 α analog, 250 μ g IM/IMM q15min to max 2 mg (major prostaglandin side effects and contraindicated in cardiovascular, pulmonary, renal, and hepatic dysfunction)
- misoprostol 600-800 μ g PO/SL (faster) or PR/PV (side effect: pyrexia if >600 μ g)
- tranexamic acid (Cyklokapron®), an antifibrinolytic, 1 g IV

Local Control

- bimanual massage: elevate the uterus and massage through patient's abdomen
- uterine packing (mesh with antibiotic treatment)
- Bakri Balloon for tamponade: may slow hemorrhage enough to allow time for correction of coagulopathy or for preparation of an OR

Surgical Therapy (Intractable PPH)

- D&C (beware of vigorous scraping which can lead to Asherman's syndrome)
- embolization of uterine artery or internal iliac artery by interventional radiologist
- laparotomy with bilateral ligation of uterine artery (may be effective), internal iliac artery (not proven), ovarian artery, or hypogastric artery, compression sutures (B-Lynch or Cho sutures)
- hysterectomy last option, with angiographic embolization if post-hysterectomy bleeding

Retained Placenta

Definition

- placenta undelivered after 30 min postpartum

Etiology

- placenta separated but not delivered
- abnormal placental implantation (placenta accreta, placenta increta, placenta percreta)

Risk Factors

- placenta previa, prior C/S, post-pregnancy curettage, prior manual placental removal, uterine infection

Clinical Features

- risk of postpartum hemorrhage and infection

Investigations

- explore uterus
- assess degree of blood loss

Management

- 2 large bore IVs, type and screen
- Brant maneuver (firm traction on umbilical cord with one hand applying suprapubic pressure cephalad to avoid uterine inversion by holding uterus in place)
- oxytocin 10 IU in 20 mL NS into umbilical vein
- manual removal if above fails
- D&C if required
- Ancef 2 g IV if manual removal or D&C

Uterine Inversion

**Definition**

- inversion of the uterus through cervix \pm vaginal introitus

Etiology/Epidemiology

- often iatrogenic (excess cord traction with fundal placenta)
- excessive use of uterine tocolytics
- more common in grand multiparous (lax uterine ligaments)
- 1/1,500-1/2,000 deliveries

Clinical Features

- can cause profound vasovagal response with bradycardia, vasodilation, and hypovolemic shock
- shock may be disproportionate to maternal blood loss

Management

- urgent management essential, call anesthesia
- ABCs: initiate IV crystalloids

- can use tocolytic drug (see Management of Preterm Labour, OB16) or nitroglycerin IV to relax uterus and aid replacement
- replace uterus without removing placenta
- remove placenta manually and withdraw slowly
- IV oxytocin infusion (only after uterus replaced)
- re-explore uterus
- may require general anesthetic ± laparotomy

Postpartum Pyrexia

Definition

- fever >38°C on any 2 of the first 10 d postpartum, except the first day

Etiology

- endometritis
- wound infection (check C/S and episiotomy sites)
- mastitis/engorgement
- UTI
- atelectasis
- pneumonia
- DVT, pelvic thrombophlebitis

Investigations

- detailed history and physical exam, relevant cultures
- for endometritis: blood and genital cultures

Treatment

- depends on etiology
 - infection: empiric antibiotics, adjust when sensitivities available
 - ♦ endometritis: clindamycin + gentamycin IV
 - ♦ mastitis: cloxacillin or cephalixin
 - ♦ wound infection: cephalixin, frequent sitz baths for episiotomy site infection
 - DVT: anticoagulants
- prophylaxis against post-C/S endometritis: administer 2g of Cephazolin IV 30 minutes prior to skin incision

ENDOMETRITIS

- definition: infection of uterine myometrium and parametrium
- clinical features: fever, chills, abdominal pain, uterine tenderness, foul-smelling discharge, or lochia
- treatment: depends on infection severity; oral antibiotics if well, IV with hospitalization in moderate to severe cases

VENOUS THROMBOEMBOLISM

- see *Venous Thromboembolism*, OB30

Mastitis

- definition: inflammation of mammary glands
- must rule out inflammatory carcinoma, as indicated
- differentiate from mammary duct ectasia: mammary duct(s) beneath nipple clogged and dilated ± ductal inflammation ± nipple discharge (thick, grey to green), often postmenopausal women

Table 24. Lactational vs. Non-Lactational Mastitis

	Lactational	Non-Lactational
Epidemiology	More common than non-lactational Often 2-3 wk postpartum	Periductal mastitis most common Mean age 32 yr
Etiology	<i>S. aureus</i>	May be sterile May be infected with <i>S. aureus</i> or other anaerobes Smoking is risk factor May be associated with mammary duct ectasia
Symptoms	Unilateral localized pain Tenderness Erythema	Subareolar pain May have subareolar mass Discharge (variable colour) Nipple inversion
Treatment	Heat or ice packs Continued nursing/pumping Antibiotics (cloxacillin/cephalexin) (erythromycin if pen-allergic)	Broad-spectrum antibiotics and I&D Total duct excision (definitive)
Abscess	Fluctuant mass Purulent nipple discharge Fever, leukocytosis Discontinue nursing, IV antibiotics (nafcillin/oxacillin), I&D usually required	If mass does not resolve, FNA to exclude cancer and U/S to assess presence of abscess Treatment includes antibiotics, aspiration, or I&D (tends to recur) May develop mammary duct fistula A minority of non-lactational abscesses may occur peripherally in breast with no associated periductal mastitis (usually <i>S. aureus</i>)

Etiology of Postpartum Pyrexia

B-5W

Breast: engorgement, mastitis

Wind: atelectasis, pneumonia

Water: UTI

Wound: episiotomy, C/S site infection

Walking: DVT, thrombophlebitis

Womb: endometritis

Risk Factors for Endometritis

C/S, intrapartum chorioamnionitis, prolonged labour, prolonged ROM, multiple vaginal examinations

Postpartum Mood Alterations

POSTPARTUM BLUES

- 40-80% of new mothers, onset day 3-10; extension of the “normal” hormonal changes and adjustment to a new baby
- self-limited, should resolve by 2 wk
- manifested by mood lability, depressed affect, increased sensitivity to criticism, tearfulness, fatigue, irritability, poor concentration/despondency, anxiety, insomnia

POSTPARTUM DEPRESSION

- definition: major depression occurring in a woman within 6 mo of childbirth (see [Psychiatry, PS12](#))
- epidemiology: 10-15%, risk of recurrence 50%
- risk factors
 - personal or family history of depression (including PPD)
 - prenatal depression or anxiety
 - stressful life situation
 - poor support system
 - unwanted pregnancy
 - colicky or sick infant
- clinical features: suspect if the “blues” last beyond 2 wk, or if the symptoms in the first 2 wk are severe (e.g. extreme disinterest in the baby, suicidal or homicidal/infanticidal ideation)
- assessment: Edinburgh Postnatal Depression Scale or other
- treatment: antidepressants, psychotherapy, supportive care, ECT if refractory
- prognosis: interferes with bonding and attachment between mother and baby, so it can have long-term effects

POSTPARTUM PSYCHOSIS

- definition: onset of psychotic symptoms over 24-72 h within first month postpartum, can present in the context of depression
- epidemiology: rare (0.2%)

Postpartum Care

Postpartum Office Visit at 6 Weeks

Care of Mother (The 10 Bs)

- **Be careful:** do not use douches or tampons for 4-6 wk post-delivery
- **Be fit:** encourage gradual increases in walking, Kegel exercises
- **Birth control:** assess for use of contraceptives; breastfeeding is NOT an effective method of birth control (see [Gynecology, GY17](#), for more detail about different contraceptive options postpartum)
- **Bladder:** assess for urinary incontinence, maintain high fluid intake
- **Blood pressure:** especially if gestational HTN
- **Blood tests:** CBC (for anemia if had PPH)
- **Blues:** (see [Postpartum Mood Alterations](#))
- **Bowel:** fluids and high-fibre foods, bulk laxatives; for hemorrhoids/perineal tenderness: pain meds, doughnut cushion, Sitz baths, ice compresses
- **Breast and pelvic exam:** watch for Staphylococcal or Streptococcal mastitis/abscess, ± Pap smear at 6 wk

The acronym “**BUBBLES**” for what to ask about when rounding on postpartum care. Modify this for C/S or vaginal delivery

Baby care and breastfeeding (latch, amount)
Uterus – firm or boggy?
Bladder function – Voiding well? Dysuria?
Bowel function – Passing gas or stool?
 Constipated?
Lochia or discharge – Any blood?
Episiotomy/laceration/incision – Pain controlled?
Symptoms of VTE – Dyspnea? Calf pain?

Physiological Changes Postpartum

- uterus weight rapidly diminishes through catabolism, cervix loses its elasticity and regains firmness
 - should involute ~1 cm below umbilicus per day in first 4-5 d, reaches non-pregnant state in 4-6 wk postpartum
- ovulation resumes in ~45 d for non-lactating women and within 3-6 mo for lactating women and sometimes later
- lochia: normal vaginal discharge postpartum, uterine decidual tissue sloughing
 - decreases and changes in colour from red (lochia rubra; presence of erythrocytes, 3-4 d) → pale (lochia serosa) → white/yellow (lochia alba; residual leukorrhea) over 3-6 wk
 - foul-smelling lochia suggests endometritis

Breastfeeding Problems

- inadequate milk: consider domperidone
- breast engorgement: cool compress, manual expression/pumping
- nipple pain: clean milk off nipple after feeds, moisture cream, topical steroid if needed
- mastitis: treat promptly (see [Postpartum Pyrexia, OB45](#))
- inverted nipples: makes feeding difficult
- maternal medications: may require pediatric consultation (see Breastfeeding and Drugs)

Bladder Dysfunction

- pelvic floor prolapse can occur after vaginal delivery
- stress or urge urinary incontinence common
- increased risk with instrumental delivery or prolonged second stage
- conservative management: pelvic floor retraining with Kegel exercises/pelvic physiotherapy, vaginal cone, or pessaries, lifestyle modifications (e.g. limit fluid, caffeine intake)
- surgical management: minimally invasive procedures (tension-free vaginal tape, transobturator tape, midurethral sling)

Puerperal Pain

- “after pains” common in first 3 d due to uterine contractions; encourage simple analgesia
- ice packs can be used on perineum if painful
- encourage regular analgesia and stool softener

Breastfeeding and Drugs

Table 25. Drug Safety During Breastfeeding

Safe During Breastfeeding	Contraindicated When Breastfeeding
Analgesics (e.g. acetaminophen, NSAIDs)	Chloramphenicol (bone marrow suppression)
Anticoagulants (e.g. heparin)	Cyclophosphamide (immune system suppression)
Antidepressants (e.g. sertraline, fluoxetine, TCAs)	Sulphonamides (in G6PD deficiency, can lead to hemolysis)
Antiepileptics (e.g. phenytoin, carbamazepine, valproic acid)	Nitrofurantoin (in G6PD deficiency, can lead to hemolysis)
Antihistamines	Tetracycline
Antimicrobials (e.g. penicillins, aminoglycosides, cephalosporins)	Lithium
β-adrenergics (e.g. propranolol, labetalol)	Phenindione
Insulin	Bromocriptine
Steroids	Anti-neoplastics and immunosuppressants
OCP (low dose) – although may decrease breast milk production	Psychotropic drugs (relative contraindication)

Breastfeeding: Contraindicated Drugs

BREAST

Bromocriptine/Benzodiazepines
Radioactive isotopes/Rizatriptan
Ergotamine/Ethosuximide
Amiodarone/Amphetamines
Stimulant laxatives/Sex hormones
Tetracycline/Tretinoin

Common Medications

Table 26. Common Medications

Drug Name (Brand Name)	Dosing Schedule	Indications/Comments
betamethasone valerate (Celestone®)	12 mg IM q24h x 2 doses	Enhancement of fetal pulmonary maturity for PTL
carboprost (Hemabate®)	0.25 mg IM/IMM q15min; max 2 mg	Treatment of uterine atony
cefazolin	2 g IV then 1 g q8h	GBS prophylaxis (penicillin allergic and not at risk for anaphylaxis)
clindamycin	900 mg IV q8h	Used in endometritis
dexamethasone	6 mg IM q12h x 4 doses	Enhancement of fetal pulmonary maturity for PTL
dinoprostone (Cervidil®: PGE2 impregnated thread)	10 mg PV (remove after 12 h) Max 3 doses	Induction of labour Advantage: can remove if uterine hyperstimulation
doxylamine succinate (Diclectin®)	2 tabs qhs + 1 tab qAM + 1 tab qPM Max 8 tabs/d	Each tablet contains 10 mg doxylamine succinate with vitamin B6 Used for hyperemesis gravidarum
erythromycin	500 mg IV q6h	GBS prophylaxis (penicillin allergic and at risk for anaphylaxis)
folic acid	0.4-1 mg PO OD x 1-3 mo preconception and T1 5 mg PO OD with past Hx of NTD/risks for NTD	Prevention of ONTD
methotrexate	50 mg/m ² IM or 50 mg PO x 1 dose	For ectopic pregnancy or medical abortion
methylergonavine maleate (Ergotamine®)	.25 mg IM/IMM q15min up to 1.25 mg or IV bolus 0.125 mg	Treatment of uterine atony
misoprostol (Cytotec®)	600-1000 µg PR x 1 dose 400 µg PO/SL x 1 dose or 800 µg PV x 1 dose 3-7 d after methotrexate	For treatment of PPH For medical abortion/retained products of conception Also used for NSAID-induced ulcers (warn patients of contraindications)
oxytocin (Pitocin®)	0.5-2.0 mU/min IV or 10 U/L NS increase by 1-2 mU/min q20-60min Max 36-48 mU/min 10 U IM at delivery of anterior shoulder and of placenta 20 U/L NS or RL IV continuous infusion	Augmentation of labour (also induction of labour) Prevention of uterine atony Treatment of uterine atony
Penicillin G	5 million U IV, then 2.5 million U IV q4h until delivery	GBS prophylaxis
PGE2 gel (Prostin® gel)	0.5 mg PV q6-12h; max 3 doses	Induction of labour
Rh IgG (Rhogam®)	300 µg IM x 1 dose	Given to Rh negative women Routinely at 28 wk GA Within 72 h of birth of Rh+ fetus Positive Kleihauer-Betke test With any invasive procedure in pregnancy Ectopic pregnancy Antepartum hemorrhage Miscarriage or therapeutic abortion (dose: 50 µg IM only)

Misoprostol (Cytotec®) is also indicated to protect against NSAID-induced gastric ulcers in non-pregnant individuals. The use of misoprostol for cytoprotection is contraindicated in pregnancy; warn female patients of this contraindication

Basic Anatomy Review

Figure 1. Anatomy of the eye

Figure 2. Layers of the retina

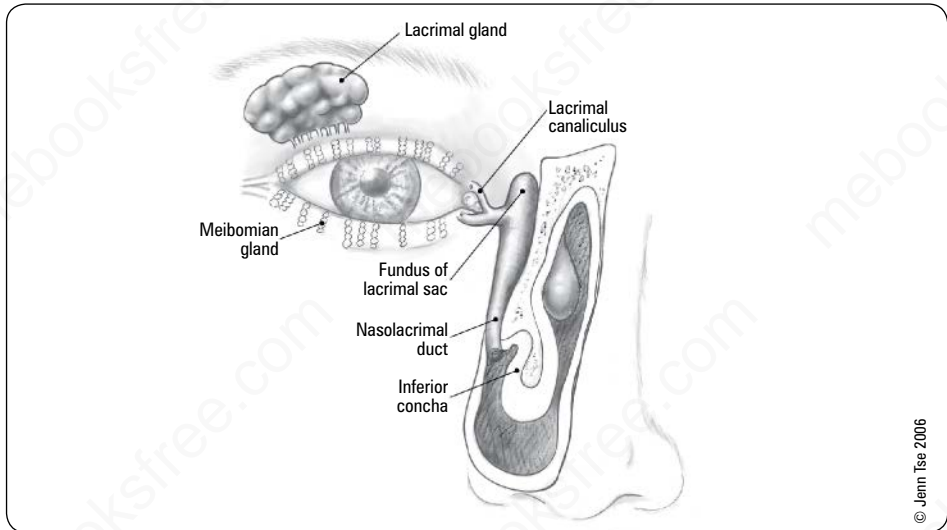

Figure 3. Tear drainage from the eye (lacrimal apparatus)

Differential Diagnoses of Common Presentations

Loss of Vision

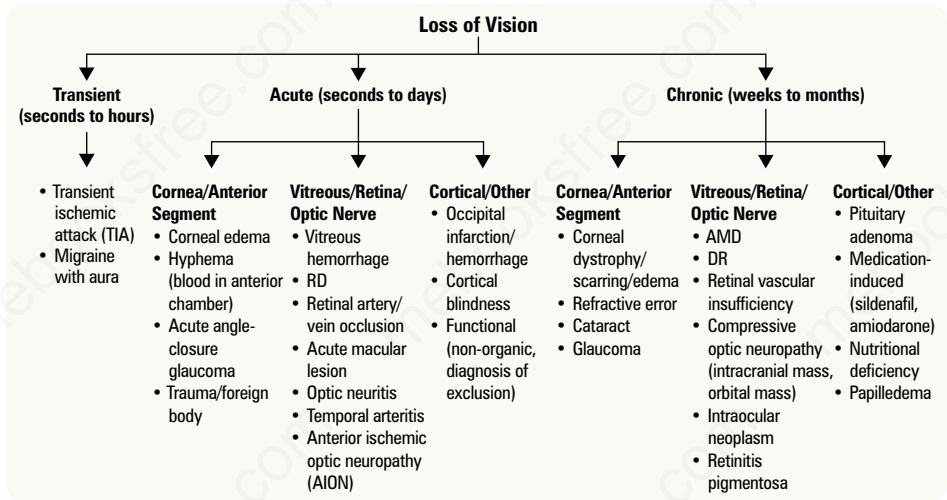

Figure 4. Loss of vision

Top 3 Differential Diagnosis of Acute Loss of Vision

- Vitreous hemorrhage
- Retinal artery/vein occlusion
- Retinal detachment

Top 3 Differential Diagnosis of Chronic Loss of Vision

Reversible

- Cataract
- Refractive error
- Corneal dystrophy
- Glaucoma

Irreversible

- AMD
- DR

Note: Anti-VEGF treatment for exudative AMD and diabetic macular edema may reverse some vision loss

Red Eye

Table 1. Common Causes of Red Eye

<p>Lids/orbit/lacrimal system</p> <ul style="list-style-type: none"> Hordeolum/chalazion Blepharitis Entropion/ectropion Foreign body/laceration Dacryocystitis/dacryoadenitis 	<p>Cornea</p> <ul style="list-style-type: none"> Foreign body (including contact lens) Keratitis Abrasion, laceration Ulcer 	<p>Other</p> <ul style="list-style-type: none"> Trauma Post-operative endophthalmitis Pharmacologic (e.g. prostaglandin analogs)
<p>Conjunctiva/sclera</p> <ul style="list-style-type: none"> Subconjunctival hemorrhage Conjunctivitis Dry eyes Pterygium Episcleritis/scleritis Preseptal/orbital cellulitis 	<p>Anterior chamber</p> <ul style="list-style-type: none"> Anterior uveitis (iritis, iridocyclitis) Acute glaucoma Hyphema (blood in anterior chamber) Hypopyon (pus in anterior chamber) 	

Ocular Pain

- differentiate from eye fatigue (asthenopia)
- ocular surface disease
- herpes zoster prodrome
- trauma/foreign body
- blepharitis
- keratitis
- corneal abrasion/ulcer
- acute glaucoma
- acute uveitis
- scleritis
- episcleritis
- optic neuritis

Floaters

- PVD (often secondary to age-related vitreous syneresis)
- vitreous hemorrhage
- retinal tear/detachment
- intermediate uveitis (pars planitis)
- posterior uveitis (chorioretinitis)

Flashes of Light (Photopsia)

- PVD (often secondary to age-related vitreous syneresis)
- retinal tear/detachment
- migraine with aura

Photophobia (Severe Light Sensitivity)

- corneal abrasion, corneal ulcer
- keratitis
- acute angle-closure glaucoma
- iritis
- meningitis/encephalitis
- migraine
- subarachnoid hemorrhage (SAH)

Diplopia (Double Vision)

Table 2. Common Causes of Diplopia

Binocular Diplopia	Monocular Diplopia
Occurs with both eyes open, eliminated with occlusion of either eye	Occurs with one eye open, remains with occlusion of unaffected eye
Causes	Causes
Disease of eye muscle: congenital strabismus syndromes	Optical factors: refractive error/astigmatism
Ocular motor nerve dysfunction: III, IV, VI Nerve Palsy	Mechanical process: dislocated lens, postoperative sequelae (cataract surgery, peripheral laser iridotomy)
Neuromuscular junction disease: myasthenia gravis, botulism	Other: strands of mucus in tear film (keratoconus)
Mechanical process: muscle restriction/entrapment, thyroid ophthalmopathy	
Supranuclear Causes	
INO (multiple sclerosis, brainstem infarct)	

Ocular Problems in the Contact Lens Wearer

- solution hypersensitivity
- tight lens syndrome
- corneal abrasion
- giant papillary conjunctivitis/contact lens allergy
- SPK from dry eyes
- limbal stem cell deficiency
- corneal neovascularization
- sterile corneal infiltrates (immunologic)
- infected ulcers (*Pseudomonas*, *Acanthamoeba*)

Acute Painless Vision Loss

- vitreous hemorrhage
- retinal artery/vein occlusion
- RD
- AION
- optic neuritis
- amaurosis fugax/TIA/stroke

Table 3. Common Differential Diagnoses of Red Eye

	Conjunctivitis	Acute Iritis	Acute Glaucoma	Keratitis (Corneal Abrasion/Ulcer)
Discharge	Bacterial: purulent			
Viral: serous/mucoid				
Allergic: mucoid	No	No	Profuse tearing	
Pain	±	++ (dull/achy)	+++ (nausea)	++ (sharp)
Photophobia	No	+++	+	++
Blurred Vision	No	++	+++	Varies
Pupil	Normal	Smaller	Fixed in mid-dilation	Same or smaller
Injection	Diffuse conjunctival injection involving the bulbar conjunctiva for 360° + palpebral or tarsal conjunctiva	Ciliary flush (peri-limbal)	Conjunctival injection	±
Limbal Pallor	Ciliary flush	Diffuse	Diffuse	No
Cornea	Normal	Keratic precipitates	Cloudy	Infiltrate, edema, and may have keratic precipitates
IOP	Normal	Varies	Increased markedly	Normal or slightly decreased
Anterior Chamber	Normal	+++ Cells and flare	Shallow	Cells and flare or normal
Other	Large, tender pre-auricular node(s) if viral		Posterior synechiae	Coloured halos
Nausea and vomiting				

Not every red eye has conjunctivitis

Ocular Emergencies

These require urgent ophthalmology consultation for management

Sight-Threatening

- lid/globe lacerations
- chemical burn
- corneal ulcer
- gonococcal conjunctivitis
- acute iritis
- acute glaucoma
- CRAO
- intraocular foreign body
- RD (especially when macula threatened)
- endophthalmitis
- GCA

Life-Threatening

- proptosis (rule out cavernous sinus fistula or thrombosis)
- CN III palsy with dilated pupil (intracranial aneurysm or externally compressive neoplastic lesion)
- papilledema (elevated increased intracranial pressure workup)
- orbital cellulitis
- leukocoria: white reflex (absent red reflex, must rule out retinoblastoma)

The Ocular Examination

Visual Acuity – Distance

- Snellen Acuity (Figure 5) = $\frac{\text{testing distance (usually 20 ft or 6 m)}}{\text{smallest line patient can read on the chart}}$
 - e.g. 20/40 = what the patient can see at 20 feet (numerator), what a “normal” person can see at 40 feet (denominator)
- distance visual acuity should be tested with distance glasses on in order to obtain best corrected visual acuity
- testing hierarchy for low vision: Snellen acuity (20/x) → counting fingers at a given distance (CF) → hand motion (HM) → light perception with projection (LP with projection) → light perception (LP) → no light perception (NLP)

Example 1

$\frac{SC}{V} \begin{matrix} 20/40 -1 \\ 20/80 +2 \end{matrix} \rightarrow 20/25 PH$

Example 2

$\frac{CC}{V} \begin{matrix} CF 3' \\ HM \end{matrix}$

Note: RIGHT EYE visual acuity always listed on top.

- V** Vision
- SC** Without correction
- CC** With correction
- 20/40 -1** All except one letter of 20/40
- 20/80 +2** All of 20/80 plus two letters of 20/70
- PH** Visual acuity with pinhole correction
- CF** Counting fingers
- HM** Hand motion

Figure 5. Ophthalmology nomenclature for visual acuity

OD = oculus dexter = right eye
OS = oculus sinister = left eye
OU = oculus uterque = both eyes

Snellen visual acuity of 20/20 equates to “normal” vision

Normal Infant and Child Visual Acuity

- 6-12 mo: 20/120
- 1-2 yr: 20/80
- 2-4 yr: 20/20

- legal blindness is BCVA that is $\leq 20/200$ in best eye
- minimum visual requirements to operate a non-commercial automobile in Ontario are: 20/50 BCVA with both eyes open and examined together, 120° continuous horizontal visual field, and 15° continuous visual field above and below fixation

Visual Acuity – Near

- use pocket vision chart (Rosenbaum Pocket Vision Screener)
- record Jaeger (J) or Point number and testing distance (usually 30 cm) e.g. J2 @ 30 cm
- conversion to distance visual acuity possible (e.g. immobile patient, no distance chart available)

Visual Acuity for Infants, Children, Non-English Speakers, and Dysphasics

- newborns
 - VA cannot be tested conventionally
- 3 mo-3 yr (can only assess visual function, not acuity)
 - test each eye for fixation symmetry using an interesting object
 - normal function noted as “CSM” = central, steady, and maintained
- 3 yr until alphabet known
 - pictures or letter cards/charts such as HOTV or Sheridan-Gardner test (children point to optotypes on a provided matching card)
 - tumbling “E” chart

Colour Vision

- test with Ishihara pseudoisochromatic plates
- record number of correctly identified plates presented to each eye, specify incorrect plates
- important for testing optic nerve function (e.g. optic neuritis, chloroquine use, thyroid ophthalmopathy)
- note: red-green colour blindness is sex-linked and occurs in 7-10% of males

VISUAL FIELDS

- test “visual fields by confrontation” (4 quadrants, each eye tested separately) for estimation of visual field loss
- accurate, quantifiable assessment with automated visual field testing (Humphrey or Goldmann) or Tangent Screen
- use Amsler grid (each eye tested separately) to check for central or paracentral scotomas (blindspots) in patients with AMD

PUPILS

- use reduced room illumination with patient focusing on distant, fixed object to prevent near reflex
- examine pupils for shape, size, symmetry, and reactivity to light (both direct and consensual response)
- test for RAPD with swinging flashlight test, check by reverse RAPD if one pupil non-reactive
- test pupillary constriction portion of near reflex by bringing object close to patient’s nose
- “normal” pupil testing often noted as PERRLA (pupils equal, round, reactive to light and accommodation)

ANTERIOR CHAMBER DEPTH

- shine light tangentially from temporal side
- if $> 2/3$ of nasal side of iris in shadow \rightarrow shallow anterior chamber

The van Herick Method (Slit Lamp technique)

- shine thin-angled slit beam onto the peripheral cornea of each eye, view at a 60° angle from the beam
- estimate depth between the posterior surface of the cornea and the iris as a proportion of corneal thickness
- ratios $\leq 1/4$ implies risk of occludable angle; however, if $> 1/4$, this does not rule out risk
- gonioscopy, as performed by an ophthalmologist, is gold-standard for assessing anterior chamber depth

EXTRAOCULAR MUSCLES

Alignment

- Hirschberg corneal reflex test
 - examine in primary position of gaze (i.e. straight ahead) with patient focusing on distant object
 - shine light into patient’s eyes from ~30 cm away
 - corneal light reflex should be at the same position on each cornea
- strabismus testing as indicated (cover test, cover-uncover test, prism testing) (see Strabismus, OP50)

Movement

- examine movement of eyeball through six cardinal positions of gaze
- ask patient if diplopia or pain is present in any position of gaze
- observe for horizontal, vertical, or rotatory nystagmus (rhythmic, oscillating movements of the eye)
- resolving horizontal nystagmus at end-gaze is usually normal

Diplopia

- see [Neurology – Neuro-ophthalmology Diplopia](#)

For patients with dark irides, test pupils using an ophthalmoscope focused on the red reflex; this will provide a better view than using a penlight

4 Ps of Inspection
 Pupil: shape, size, symmetry
 Position: esotropia, exotropia, central
 Ptosis
 Primary nystagmus

Figure 6. Ophthalmology nomenclature for visual fields by confrontation

Figure 7. Estimation of anterior chamber depth

SLIT-LAMP EXAMINATION

Ocular Adnexa

- lids, lashes, lacrimal system

Anterior Segment

- conjunctiva / sclera
- cornea
 - fluorescein dye: stains de-epithelialized cornea; dye appears fluorescent green with cobalt blue filtered light
 - Rose Bengal dye: stains devitalized corneal epithelium
- anterior chamber/angle (Van Herick)
- iris/pupil
- lens (assess for cataract)
- anterior vitreous

Posterior Segment (requires 78D or 90D lens)

- vitreous
- optic disc (colour, C:D ratio, sharpness of disc margin)
- macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
- retinal vessels
- retinal background

TONOMETRY

- measurement of IOP
- normal range is 9-21 mmHg (average 15 mmHg)
- IOP has diurnal variation, so always record the time of day at which the measurement was taken
- commonly measured by
 - GAT: clinical gold standard, performed using the slit-lamp with special tip (prism)
 - Tono-Pen®: benefit is portability and use of disposable probe tips; use when cornea is scarred/asymmetric (GAT inaccurate)
 - air puff (non-contact and least reliable)
- use topical anesthetic for GAT and Tono-Pen®; apply fluorescein dye when using GAT

DIRECT OPHTHALMOSCOPY

- best performed with pupils dilated (for list of mydriatics and cycloplegics see Table 13, OP58)
 1. assess red reflex
 - ♦ light reflected off the retina produces a “red reflex” when viewed from ~1 foot away
 - ♦ anything that interferes with the passage of light will diminish the red reflex (e.g. large vitreous hemorrhage, cataract, retinoblastoma)
 2. examine the posterior segment of the eye
 - ♦ vitreous
 - ♦ optic disc (colour, C:D ratio, sharpness of disc margin)
 - ♦ macula (~1.5-2 disc diameters temporal to disc), fovea (foveal light reflex)
 - ♦ retinal vessels
 - ♦ retinal background
- contraindications to pupillary dilatation
 - shallow anterior chamber – can precipitate acute angle-closure glaucoma
 - iris-supported anterior chamber lens implant
 - potential neurologic abnormality requiring pupil evaluation
 - use caution with cardiovascular disease – mydriatics may cause tachycardia and hypertension

Figure 8. Diagnostic positions of gaze for isolated primary actions of extraocular muscles

Extraocular Muscle Innervations

LR6 S04 AE3

- Lateral Rectus via CN VI
- Superior Oblique via CN IV
- All Else via CN III (superior, medial, and inferior rectus, inferior oblique)

Aqueous Flare

- Resembles dust particles in a beam of light
- Results from protein leaking from blood vessels
- Distinguish from aqueous cells (individual cells in anterior chamber)

Note: RIGHT EYE drawn on the left, LEFT EYE drawn on the right (as if looking at patient’s face)

- LLL** Lids, lashes, lacrimal
- SC** Sclera, conjunctiva
- K** Cornea
- AC** Anterior chamber
- d+q** Deep (not shallow) and quiet (no cells in AC)
- NS** Nuclear sclerosis (cataract)

Any abnormality or pathology is drawn on the sketch in the appropriate location, and is labelled (e.g. trichiasis, conjunctivitis/episcleritis/scleritis, corneal abrasion/ulcer, foreign body, etc.)

Figure 9. Slit-lamp examination note

Figure 10. Tonometry

Optics

REFRACTION

- two techniques used
 - flash/streak retinoscopy: refractive error determined objectively by the examiner using lenses and retinoscope
 - manifest: subjective trial using loose lenses or a phoropter (device the patient looks through that is equipped with lenses)
 - cycloplegic: manifest refraction with accommodation temporarily paralyzed with cycloplegics
- a typical lens prescription would contain
 - sphere power in dioptre (measurement of refractive power of lens, equal to reciprocal of focal length in metres)
 - cylinder power in dioptre to correct astigmatism
 - axis of cylinder in degrees
 - “add” (bifocal/progressive reading lens) for presbyopes
 - e.g. -1.50 + 1.00 x 120 degrees, add +2.00

REFRACTIVE EYE SURGERY

- permanently alters corneal refractive properties by ablating tissue to change curvature of the cornea
- used for correction of myopia, hyperopia, and astigmatism
- common types include PRK and LASIK
- potential risks/side-effects: infection, under/overcorrection, increased glare/halo perception at night, corneal haze (PRK only), dry eyes (more common in LASIK than PRK), regression, and flap complications such as free cap (loss of flap), traumatic flap dislocations, buttonhole flap, and epithelial in growth (LASIK only)

Table 4. Optics

	Pathophysiology	Clinical Features	Treatment	Complications
Emmetropia	Image of distant objects focus exactly on the retina	No refractive error		
Myopia	Globe too long relative to refractive mechanisms, or refractive mechanisms too strong Light rays from distant object focus in front of retina → blurring of (distance) vision	“Nearsightedness” Usually presents in 1st or 2nd decade, stabilizes in 2nd and 3rd decade; rarely begins after age 25 except in patients with DM or cataracts Blurring of distance vision; near vision usually unaffected Prevalence: 30-40% in U.S. population	Correct with negative diopter/ concave/“negative” lenses to diverge light rays Refractive eye surgery	Retinal tear/ detachment, macular hole, open angle glaucoma Other complications that are not prevented with refractive correction
Hyperopia	Globe too short relative to refractive mechanisms, or refractive mechanisms too weak Light rays from distant object focus behind retina → blurring of near ± distant vision May be developmental or due to any etiology that shortens globe	“Farsightedness” Youth: usually do not require glasses (still have sufficient accommodative ability to focus image on retina), but may develop accommodative esotropia (see <i>Strabismus</i> , OP36) 30s-40s: blurring of near vision due to decreased accommodation, may need reading glasses >50s: blurring of distance vision due to severely decreased accommodation	When symptomatic, correct with positive diopter/convex/“plus” lenses to converge light rays Refractive eye surgery	Angle-closure glaucoma, particularly later in life as lens enlarges
Astigmatism	Light rays not refracted uniformly in all meridians due to non-spherical surface of cornea or non-spherical lens (e.g. football-shaped) Two types Regular – curvature uniformly different in meridians at right angles to each other Irregular – distorted cornea caused by injury, keratoconus (cone-shaped cornea), corneal scar, or severe dry eye	Affects ~30% of population, with prevalence increasing with age Mild astigmatism unnoticeable Higher amounts of astigmatism may cause blurry vision, squinting, asthenopia, or headaches	Correct with cylindrical lens (if regular) Try contact lens (if irregular) Refractive eye surgery	
Presbyopia	Normal aging process (>40 yr) Hardening/reduced deformability of lens results in decreased accommodative ability Accommodative power is 14D at age 10, diminishes to 3.5D by age 40 yr Near images cannot be focused onto the retina (focus is behind the retina as in hyperopia)	If initially emmetropic, person begins to hold reading material farther away, but distance vision remains unaffected If initially myopic, person removes distance glasses to read If initially hyperopic, symptoms of presbyopia occur earlier	Correct with positive diopter/convex/“plus” lenses for reading	
Anisometropia	Difference in refractive errors between eyes			Second most common cause of amblyopia in children

Central Corneal Thickness (CCT)

Average CCT = 550 μm
By GAT, IOP is over-estimated with thick corneas and under-estimated with thin corneas

Myopia

LMN
Long globe
Myopic
Negative correction/Nearsighted

Figure 11. Emmetropia and refractive errors

Structures Responsible for Refractive Power

- Cornea (2/3)
- Lens (1/3)

Figure 12. Correction of refractive errors

The Orbit

Globe Displacement

Table 5. Exophthalmos (Proptosis) and Enophthalmos

	Exophthalmos (Proptosis)	Enophthalmos
Definition	Anterior displacement (protrusion) of the globe Exophthalmos generally refers to an endocrine etiology or protrusion of >18 mm (as measured by a Hertel exophthalmometer) Proptosis generally refers to other etiologies (e.g. cellulitis) or protrusion of >18 mm	Posterior displacement (retraction) of the globe
Investigations	CT/MRI head/orbits, ultrasound orbits, thyroid function tests	CT/MRI orbits
Etiology	Note: rule out pseudoexophthalmos (e.g. lid retraction) Graves' disease (unilateral or bilateral, most common cause in adults) Orbital cellulitis (unilateral, most common cause in children) 1° or 2° orbital tumours Orbital/retrobulbar hemorrhage Cavernous sinus thrombosis or fistula	"Blow-out" fracture (see <i>Ocular Trauma, OP39</i>) Orbital fat atrophy Congenital abnormality Metastatic disease

Preseptal Cellulitis

- infection of soft tissue anterior to orbital septum

Etiology

- usually follows periorbital trauma or dermal infection

Clinical Features

Table 6. Clinical Features of Preseptal and Orbital Cellulitis

Finding	Preseptal Cellulitis	Orbital Cellulitis
Fever	May be present	Present
Lid edema	Moderate to severe	Severe
Conjunctival injection	Absent	Present
Chemosis	Absent or mild	Marked
Proptosis	Absent	Present
Pain on eye movement	Absent	Present
Ocular mobility	Normal	Decreased
Vision	Normal	Diminished ± diplopia
RAPD	Absent	May be seen if severe
Leukocytosis	Moderate	Marked
ESR	Normal or elevated	Elevated
Additional findings	Skin infection	Sinusitis, dental abscess

Treatment

- systemic antibiotics (suspect *H. influenzae* in children; *S. aureus* or *Streptococcus* in adults)
 - e.g. amoxicillin-clavulanic acid
- if severe or child <1 yr, treat as orbital cellulitis

Orbital Cellulitis

- OCULAR and MEDICAL EMERGENCY**
- inflammation of orbital contents posterior to orbital septum
- common in children, elderly, and immunocompromised

Etiology

- usually secondary to sinus/facial/tooth infections or trauma, can also arise from preseptal cellulitis

Clinical Features (see Table 6)

Treatment

- admit, blood cultures x2, orbital CT, IV antibiotics (ceftriaxone + vancomycin) for 1 wk
- surgical drainage of abscess with close follow-up, especially in children

Complications

- optic nerve inflammation, cavernous sinus thrombosis, meningitis, brain abscess with possible loss of vision, and death

Role of Oral Corticosteroids in Orbital Cellulitis
Am J Ophthalmol 2013;156:178-183
Purpose: To evaluate the role of oral corticosteroids as an anti-inflammatory adjunct for the treatment of orbital cellulitis.
Study: RCT. Patients with acute onset (within 14 d) of orbital cellulitis with or without abscess. 21 patients total (7 patients in group 1: standard intravenous antibiotics; 14 patients in group 2: adjuvant steroids).
Results: Patients in group 2 showed earlier resolution of periorbital edema, conjunctival chemosis, pain, proptosis, and EOM deficits, including decreased duration of intravenous antibiotics and hospital stay ($p < 0.05$ for all).
Conclusion: The use of oral steroids as an adjunct to intravenous antibiotics for orbital cellulitis may decrease inflammatory symptoms with a low risk of worsening infection.

Orbital cellulitis is life-threatening if untreated (mortality of 17-20% without antibiotic use); prompt diagnosis and treatment is essential

Lacrimal Apparatus

- tear film made up of three layers
 - outer oily layer (reduces evaporation): secreted by the Meibomian glands
 - middle watery layer (forms the bulk of the tear film): constant secretion from conjunctival glands and reflex secretion by lacrimal gland with ocular irritation or emotion
 - inner mucinous layer (aids with tear adherence to cornea): secreted by conjunctival goblet cells
- tears drain from the eyes through the upper and lower lacrimal puncta → superior and inferior canaliculi → lacrimal sac → nasolacrimal duct → nasal cavity behind inferior concha (Figure 3)

Dry Eye Syndrome (Keratoconjunctivitis Sicca)

Etiology

- aqueous-deficient
 - Sjögren syndrome (autoimmune etiology e.g. RA, SLE)
 - non-Sjögren syndrome (idiopathic age-related disease; lacrimal gland scarring e.g. trachoma; decreased secretion e.g. contact lenses, CN VII palsy, anticholinergics, antihistamines, diuretics, β -blockers)
- evaporative (normal lacrimal function, excessive evaporation of aqueous layer)
 - Meibomian gland dysfunction (posterior blepharitis)
 - vitamin A deficiency (xerophthalmia with goblet cell dysgenesis)
 - eyelid abnormalities e.g. ectropion, CN VII palsy (decreased blinking)
 - topical ocular medications with preservatives
 - contact lenses, allergic conjunctivitis
- mixed etiologies are common

Clinical Features

- dry eyes, red eyes, foreign body sensation, blurred vision, tearing
- slit-lamp exam: decreased tear meniscus, decreased tear break-up time (normally should be 10 s), punctate staining of cornea with fluorescein

Investigations

- surface damage observed with fluorescein/Rose Bengal staining
- decreased distance in Schirmer's test

Complications

- erosions and scarring of cornea

Treatment

- medical: preservative-free artificial tears up to q1h and ointment at bedtime (preservative toxicity becomes significant if used more than 4-6x/day), short course of mild topical corticosteroid, omega-3 fatty acids orally, and eyelid hygiene for blepharitis
 - for moderate cases, cyclosporine ophthalmic emulsion 0.05% (Restasis®) can be used
- procedural: punctal occlusion (punctal plug insertion), lid taping, tarsorrhaphy (sew lids together) if severe
- treat underlying cause

Long-term use of artificial tears with preservatives should be avoided when treating dry eyes

Epiphora (Excessive Tearing)

Etiology

- emotion, pain
- environmental stressor (cold, wind, pollen, sleep deprivation)
- lid/lash malposition: ectropion, entropion, trichiasis
- inflammatory: conjunctivitis, dacryoadenitis, uveitis, keratitis, corneal foreign body
- dry eyes (reflex tearing)
- lacrimal drainage obstruction (congenital failure of canalization, aging, rhinitis, dacryocystitis)
- paradoxical gustatory lacrimation reflex (crocodile tears)

Investigations

- using fluorescein dye, examine for punctal reflux by pressing on canaliculi
- Jones dye test: fluorescein placed in conjunctival cul-de-sac, and cotton applicator placed in nose to detect flow (i.e. rule out lacrimal drainage obstruction)

Treatment

- lid repair for ectropion or entropion
- eyelash removal for trichiasis
- punctal irrigation (dilation and irrigation)
- nasolacrimal duct probing (infants)
- tube placement: temporary (Crawford) or permanent (Jones)
- surgical: dacryocystorhinostomy – forming a new connection between the lacrimal sac and the nasal cavity

Excessive tearing can be caused by dry eyes – if the tear quality is insufficient, "reflex tearing" may occur

Dacryocystitis

- acute or chronic infection of the lacrimal sac
- most commonly due to obstruction of the nasolacrimal duct
- commonly associated with *S. aureus*, *S. pneumoniae*, *Pseudomonas* species

Clinical Features

- pain, swelling, redness over lacrimal sac at medial canthus
- epiphora, crusting, \pm fever
- digital pressure on the lacrimal sac may extrude pus through the punctum
- in the chronic form, epiphora may be the only symptom

Treatment

- warm compresses, nasal decongestants, systemic and topical antibiotics
- if chronic, obtain cultures by aspiration
- once infection resolves, consider dacryocystorhinostomy

Dacryoadenitis

- inflammation of the lacrimal gland (outer third of upper eyelid)
- acute causes: *S. aureus*, mumps, EBV, herpes zoster, *N. gonorrhoeae*
- chronic causes (often bilateral): lymphoma, leukemia, sarcoidosis, tuberculosis, thyroid ophthalmopathy

Clinical Features

- pain, swelling, tearing, discharge, redness of the outer region of the upper eyelid
- chronic form is more common and may present as painless enlargement of the lacrimal gland

Treatment

- supportive: warm compresses, oral NSAIDs
- systemic antibiotics if bacterial cause
- if chronic, treat underlying disorder

Lids and Lashes

Lid Swelling

Etiology

- commonly due to allergy, with shriveling of skin between episodes
- dependent edema on awakening (e.g. CHF, renal or hepatic failure)
- orbital venous congestion due to mass or cavernous sinus fistula
- dermatochalasis (loose skin due to aging or heredity)
- lid cellulitis, thyroid disease (e.g. myxedema), trauma, chemosis

Ptosis

- drooping of upper eyelid

Etiology

- aponeurotic: disinsertion or dehiscence of levator aponeurosis (most common)
 - associated with advancing age, trauma, surgery, pregnancy, chronic lid swelling
- mechanical
 - incomplete opening of eyelid due to mass or scarring
- neuromuscular
 - myasthenia gravis (neuromuscular palsy), myotonic dystrophy
 - CN III palsy
 - Horner's syndrome (see *Constricted Pupil, Horner's Syndrome, OP30*)
- congenital
- pseudoptosis (e.g. dermatochalasis, enophthalmos, contralateral exophthalmos)
- drugs (e.g. high dose opioids, heroin abuse, pregabalin)

Treatment

- surgery (e.g. blepharoplasty, levator resection, Müller's muscle resection, frontalis sling)

Trichiasis

- eyelashes turned inwards
- may result from entropion, involutional age change, chronic inflammatory lid diseases (e.g. blepharitis), trauma, burns
- patient complains of red eye, foreign body sensation, significant discomfort, tearing
- may result in corneal ulceration and scarring

Treatment

- topical lubrication, repeat eyelash epilation, electrolysis, cryotherapy

Entropion

- lid margin turns in towards globe causing tearing, foreign body sensation, and red eye
- most commonly affects lower lid
- may cause corneal abrasions with secondary corneal scarring

Etiology

- involutional (aging)
- cicatricial (herpes zoster, surgery, trauma, burns)
- orbicularis oculi muscle spasm
- congenital

Treatment

- lubricants, evert lid with tape, surgery

Ectropion

- lid margin turns outward from globe causing tearing and possibly exposure keratitis

Etiology

- involutional (aging)
- paralytic (CN VII palsy)
- cicatricial (burns, trauma, surgery)
- mechanical (lid edema, tumour, herniated fat)
- congenital

Treatment

- topical lubrication, eyelid taping overnight, surgery

Hordeolum (Stye)

- acute inflammation of eyelid gland: either Meibomian glands (internal lid), glands of Zeis (modified sweat gland) or Moll (modified sebaceous gland in external lid)
- infectious agent is usually *S. aureus*
- painful, red swelling of lid

Treatment

- warm compresses, lid care, gentle massage
- topical antibiotics are typically ineffective
- usually resolves within 2 wk, but may require incision and drainage

Chalazion

- chronic granulomatous inflammation of Meibomian gland often preceded by an internal hordeolum
- acute inflammatory signs are usually absent
- differential diagnosis: basal cell carcinoma, sebaceous cell adenoma, Meibomian gland carcinoma

Treatment

- warm compresses
- if no improvement after 1 mo, consider incision and curettage
- chronic recurrent lesion must be biopsied to rule out malignancy

Testing for Entropion

Forced lid closure: Ask patient to tighten lid then open. In entropion, lid rolls inwards

Testing for Ectropion

Snapback test: Pull eyelid inferiorly. In ectropion, lid remains away from globe

Hordeolum vs. Chalazion

Hordeolums are due to an infectious etiology, whereas chalazions are granulomatous inflammation

Blepharitis

- inflammation of lid margins

Etiology

- Anterior blepharitis
 - staphylococcal (*S. aureus*): ulcerative, dry scales
 - seborrheic: no ulcers, greasy scales
- Posterior blepharitis
 - Meibomian gland dysfunction

Clinical Features

- itching, tearing, foreign body sensation
- thickened, red lid margins, crusting, discharge with pressure on lids ("toothpaste sign")

Complications

- recurrent hordeola
- conjunctivitis
- keratitis (from poor tear film)
- corneal ulceration and neovascularization

Treatment

- warm compresses, lid massages, and lid washing using commercially available eyelid scrub solution
- topical or systemic antibiotics as needed
- if severe, ophthalmologist may prescribe a short course of topical corticosteroids, omega-3 fatty acids

Xanthelasma

- eyelid xanthoma (lipid deposits in dermis of lids)
- appear as pale, slightly elevated yellowish plaques or streaks
- most commonly on the medial upper lids, often bilateral
- associated with hyperlipidemia (~50% of patients)
- common in the elderly, more concerning in the young

Treatment

- excision for cosmesis only, commonly recurs

Conjunctiva

- thin, vascular mucous membrane
- bulbar conjunctiva: lines sclera to limbus (junction between cornea and sclera)
- palpebral (tarsal) conjunctiva: lines inner surface of eyelid

Pinguecula

- yellow-white subepithelial deposit of hyaline and elastic tissue adjacent to the nasal or temporal limbus, sparing the cornea
- associated with sun and wind exposure, aging
- benign, sometimes enlarges slowly
- may be irritating due to abnormal tear film formation over the deposits
- surgery for cosmesis only
- irritative symptoms may be treated with lubricating drops

Pterygium

- fibrovascular, triangular, wing-like encroachment of epithelial tissue onto the cornea
- may induce astigmatism, decrease vision
- excision for chronic inflammation, threat to visual axis, cosmesis
- irritative symptoms may be treated with lubricating drops
- one-third recur after excision, lower recurrence with conjunctival autograft (~5%)

Subconjunctival Hemorrhage

- blood beneath the conjunctiva, otherwise asymptomatic
- idiopathic or associated with trauma, Valsalva maneuver, bleeding disorders, HTN, anticoagulation
- give reassurance if no other ocular findings, resolves spontaneously in 2-3 wk
- 360 degree involvement should be highly suspicious for globe rupture if trauma history
- if recurrent, consider medical/hematologic workup

Conjunctivitis

Etiology

- infectious
 - bacterial, viral, chlamydial, gonococcal, fungal, parasitic
- non-infectious
 - allergic, atopic, seasonal, giant papillary conjunctivitis (contact lens wearers)
 - toxic: irritants, dust, smoke, irradiation
 - secondary to another disorder: dacryocystitis, dacryoadenitis, cellulitis, systemic inflammatory disease

Clinical Features

- red eye (conjunctival injection often with limbal pallor), chemosis, corneal subepithelial infiltrates
- itching, foreign body sensation, tearing, discharge, crusting of lashes in the morning, lid edema
- ± preauricular and/or submandibular nodes
- follicles: pale lymphoid elevations of the conjunctiva, overlain by vessels
- papillae: fibrovascular elevations of the conjunctiva with central network of finely branching vessels (cobblestone appearance)

ALLERGIC CONJUNCTIVITIS

- associated with rhinitis, asthma, dermatitis, hay fever
- ocular pruritus, small papillae, chemosis, redness, thickened and erythematous lids
- seasonal (pollen, grasses, plant allergens)

Treatment

- allergen avoidance, cool compresses, non-preserved artificial tears, topical or oral antihistamine, topical mast cell stabilizer (e.g. cromolyn, ketotifen, olopatadine), topical corticosteroids

Atopic Conjunctivitis

- onset late adolescence and early adulthood with peak between 30-50 years old
- intense ocular pruritus (perennially), tearing, burning, clear mucus discharge, redness, blurry vision, photophobia, and foreign body sensation
- thickened and intermittent swelling of the eyelids, conjunctival chemosis, conjunctival hyperemia, and tarsal papillary hypertrophy

Treatment

- calcineurin inhibitor ointment (e.g. tacrolimus and pimecrolimus), and topical corticosteroid (clobetasone)

Giant Papillary Conjunctivitis

- immune reaction to mucus debris on lenses in contact lens wearers
- large papillae form on superior palpebral conjunctiva

Treatment

- clean, change or discontinue use of contact lens, topical corticosteroids

Vernal Conjunctivitis

- large papillae (cobblestones) form on superior palpebral conjunctiva with corneal ulcers and keratitis
- seasonal (warm weather)
- occurs in children, lasts for 5-10 yr then resolves

Treatment

- non-preserved artificial tears, consider topical steroid, topical cyclosporine (by ophthalmologist)

VIRAL CONJUNCTIVITIS (pink eye)

- presents with itchiness, pain and swelling
- serous discharge, lid edema, follicles, pseudomembranes
- subepithelial corneal infiltrates
- preauricular node often palpable and tender
- initially unilateral, often progresses to the other eye within a few days
- mainly due to adenovirus – highly contagious for up to 12 d

Treatment

- cool compresses, topical lubrication.
- usually self-limiting (7-12 d)
- proper hygiene is important to prevent transmission

BACTERIAL CONJUNCTIVITIS

- purulent discharge, lid swelling, papillae, conjunctival injection, chemosis
- common agents include *S. aureus*, *S. pneumoniae*, *H. influenzae* and *M. catarrhalis*
- in neonates or if sexually active must consider *N. gonorrhoeae* (invades cornea to cause keratitis)
- *C. trachomatis* is the most common cause in neonates

Treatment

- topical broad-spectrum antibiotic, systemic antibiotics if indicated (especially in neonates and children)
- usually a self-limited course of 10-14 d if no treatment, 1-3 d with treatment

Types of Discharge

- Allergic: mucoid
- Viral: watery
- Bacterial: purulent
- Chlamydial: mucopurulent

- Follicles are usually seen in viral and chlamydial conjunctivitis
- Papillae are usually seen in allergic and bacterial conjunctivitis

Antibiotics vs. Placebo for Acute Bacterial Conjunctivitis

Cochrane DB Syst Rev 2012;9:CD001211

Purpose: To assess the benefits and harms of antibiotic therapy in the management of acute bacterial conjunctivitis.

Criteria: RCTs with any form of antibiotic treatment compared with placebo including topical, systemic or combined (e.g. antibiotics and steroids) antibiotic treatments.

Results: 11 RCTs, 3,673 participants. Topical antibiotics improve early (2-5 d) clinical and microbiological remission rates (RR 1.36, 95% CI 1.15-1.61; RR 1.55; 95% CI 1.37-1.76) and benefit clinical remission and microbiological cure rates at a late time point (6-10 d) (RR 1.21, 95% CI 1.10-1.33; RR 1.37, 95% CI 1.24-1.52). By 6-10 d 41% of cases had resolved in the placebo group. No serious outcomes were reported in any group.

Conclusion: The use of antibiotic eye drops is associated with modestly improved rates of clinical and microbiological remission in comparison to placebo. Antibiotic eye drops should therefore be considered in order to speed the resolution of symptoms and infection although acute bacterial conjunctivitis is frequently self-limiting.

- Enlarged lymph nodes suggest infectious etiology, especially viral or chlamydial conjunctivitis
- Temporal conjunctival lymphatics drain to preauricular nodes, and nasal to submandibular nodes

GONOCOCCAL AND CHLAMYDIAL CONJUNCTIVITIS

- caused by *N. gonorrhoeae* and *C. trachomatis*, respectively
- affects sexually active individuals, neonates (ophthalmia neonatorum) in first 5 d of life when caused by gonorrhea (shorter incubation period) and d 3-14 of life when caused by chlamydia (longer incubation period)
- newborn prophylaxis with 0.5% erythromycin ointment no longer recommended
- chlamydia causes trachoma and inclusion conjunctivitis (different serotypes)

Trachoma

- leading infectious cause of blindness in the world
- severe keratoconjunctivitis leads to corneal abrasion, ulceration, and scarring
- initially, follicles on superior palpebral conjunctiva and later palpebral scarring (Arlt's line)

Treatment

- oral azithromycin and topical tetracycline

Inclusion Conjunctivitis

- chronic conjunctivitis with follicles and subepithelial infiltrates
- most common cause of conjunctivitis in newborns
- newborn prophylaxis with 0.5% erythromycin ointment no longer recommended

Treatment

- oral azithromycin, tetracycline, doxycycline

Preventing Ophthalmia Neonatorum

Paediatr Child Health 2015;20(2):93-96

The use of silver nitrate as prophylaxis for neonatal ophthalmia was instituted in the late 1800s to prevent the devastating effects of neonatal ocular infection with *Neisseria gonorrhoeae*. At that time – during the preantibiotic era – many countries made such prophylaxis mandatory by law. Today, neonatal gonococcal ophthalmia is rare in Canada, but ocular prophylaxis for this condition remains mandatory in some provinces/territories. Silver nitrate drops are no longer available and erythromycin, the only ophthalmic antibiotic eye ointment currently available for use in newborns, is of questionable efficacy. Ocular prophylaxis is not effective in preventing chlamydial conjunctivitis. Applying medication to the eyes of newborns may result in mild eye irritation and has been perceived by some parents as interfering with mother-infant bonding. Physicians caring for newborns should advocate for rescinding mandatory ocular prophylaxis laws. More effective means of preventing ophthalmia neonatorum include screening all pregnant women for gonorrhea and chlamydia infection, and treatment and follow-up of those found to be infected. Mothers who were not screened should be tested at delivery. Infants of mothers with untreated gonococcal infection at delivery should receive ceftriaxone. Infants exposed to chlamydia at delivery should be followed closely for signs of infection.

Sclera

- white fibrous outer protective coat of the eye, composed of irregularly distributed collagen bundles
- continuous with the cornea anteriorly and the dura of the optic nerve posteriorly
- episclera is a thin layer of vascularized tissue between the sclera and conjunctiva

Episcleritis

- immunologically mediated inflammation of episclera
- 1/3 bilateral; simple (80%) or nodular (20%)
- more frequent in women than men (3:1)

Etiology

- mostly idiopathic
- associated with collagen vascular diseases, infections (herpes zoster, herpes simplex, syphilis), inflammatory bowel disease, rosacea, atopy

Clinical Features

- may have discomfort and pain associated with red eye (often interpalpebral)
- sectoral or diffuse injection of radially-directed vessels, chemosis, small mobile nodules
- blanches with topical phenylephrine (constricts superficial vessels)

Treatment

- generally self-limited, recurrent in 2/3 of cases
- topical steroid (prescribed and monitored by ophthalmologist)
- oral NSAID

To differentiate between episcleritis and scleritis, place a drop of phenylephrine 2.5% (Mydrin®; AK-Dilate®) in the affected eye. Re-examine the vascular pattern 10-15 min later; in episcleritis the episcleral vessels should blanch with phenylephrine

Scleritis

- usually unilateral: can be classified as anterior or posterior and diffuse, nodular, necrotizing with inflammation, or necrotizing without inflammation (scleromalacia perforans)
- anterior scleritis: pain radiating to face, may cause scleral thinning, in some cases necrotizing
- posterior scleritis: rapidly progressive blindness, may cause exudative RD
- more common in women and elderly

Etiology

- may be a manifestation of systemic disease
- collagen vascular disease, e.g. SLE, RA, GPC, ankylosing spondylitis
- granulomatous, e.g. tuberculosis, sarcoidosis, syphilis
- metabolic, e.g. gout, thyrotoxicosis
- infectious, e.g. *S. aureus*, *S. pneumoniae*, *P. aeruginosa*, herpes zoster
- chemical or physical agents, e.g. thermal, alkali, or acid burns
- idiopathic

Clinical Features

- severe “deep” or “boring” pain, photophobia, red eye, decreased vision
- pain is best indicator of disease progression
- inflammation of scleral, episcleral, and conjunctival vessels

Scleromalacia Perforans

- Asymptomatic anterior necrotizing scleritis without inflammation
- Strongly associated with RA
- May result in scleral thinning
- Traumatic perforation can easily occur – examine eye very gently

- may have anterior chamber cells and flare, corneal infiltrate, scleral thinning, scleral edema
- sclera may have a purple or “violaceous” hue (best seen in natural light), due to rearranged scleral fibres
- failure to blanch with topical phenylephrine

Treatment

- **vision threatening** – needs to be referred to ophthalmology
- life threatening- indicator of poor systemic disease control with an increased 5 year mortality rate (not from scleritis) without treatment of underlying untreated or unrecognized autoimmune condition
- systemic NSAID, systemic steroid, and systemic immunomodulation
- treat underlying etiology

Cornea

- function
 - transmission of light
 - refraction of light (2/3 of total refractive power of eye)
 - barrier against infection, foreign bodies
- transparency due to avascularity, uniform collagen structure and deturgescence (relative dehydration)
- 5 layers (anterior to posterior): epithelium, Bowman’s layer, stroma, Descemet’s membrane, and the endothelium (dehydrates the cornea; dysfunction leads to corneal edema). Some have argued the existence of a 6th layer, “Dua’s layer”, although it is debated if this is a truly unique and additional layer.
- extensive sensory fibre network (V1 distribution); therefore abrasions are very painful

Foreign Body

- foreign material in or on cornea
- may have associated rust ring if metallic
- patients may note pain, tearing, photophobia, foreign body sensation, red eye
- signs include foreign body, conjunctival injection, epithelial defect that stains with fluorescein, corneal edema, anterior chamber cells/flare

Complications

- abrasion, infection, ulcer, scarring, rust ring, secondary iritis

Treatment

- remove under magnification using local anesthetic and sterile needle or refer to ophthalmology for removal under magnification (depending on depth and location)
- treat as per corneal abrasion

Corneal Abrasion

- epithelial defect usually due to trauma (e.g. fingernails, paper, twigs), contact lens (Figure 14)

Clinical Features (Table 7)

- pain, redness, tearing, photophobia, foreign body sensation
- de-epithelialized area stains with fluorescein dye
- pain relieved with topical anesthetic (DO NOT use for treatment- risk of corneal melt or infection)

Complications

- infection, ulceration, recurrent erosion, secondary iritis

Treatment

- topical antibiotic (drops or ointment), abrasion from organic material should be covered against pseudomonas
- consider topical NSAID (caution due to risk of corneal melt with prolonged use), cycloplegic (relieves pain and photophobia by paralyzing ciliary muscle), patch
- most abrasions clear spontaneously within 24-48 h

Recurrent Erosions

- recurrent episodes of pain, photophobia, foreign body sensation with a spontaneous corneal epithelial defect
- usually occurs upon awakening
- associated with improper adherence of epithelial cells to the underlying basement membrane

Etiology

- previous traumatic corneal abrasion
- corneal dystrophy
- idiopathic

Learn the Layers of the Cornea

ABCDE

- Anterior epithelium
- Bowman’s Membrane
- Corneal Stroma
- Dua’s Layer, Descemet’s Membrane
- Endothelium

A new corneal layer was discovered by H. Dua in 2013 and is characterized as a pre-Descemet’s membrane

Foreign body behind lid may cause multiple vertical corneal epithelial abrasions due to blinking

Topical analgesics should only be used to facilitate examination. They should NEVER be used as treatment for any ocular problem

Corneal abrasions from organic matter (e.g. twig, finger nail, etc.) have higher recurrence, even years later

Corneal Abrasion: To Patch or Not to Patch

Patching for corneal abrasion.
Cochrane DB Syst Rev 2006;2:CD004764
Results: 12 RCTs/Quasi-RCTs identified, n=1080.
 At 24 hours: people receiving patch were less likely to have a healed abrasion (RR 0.89, 95% CI 0.79-1.00). At 48 hours: similar effect for both groups (RR 0.97, 95% CI 0.91-1.02). At 72 hours: similar effect for both groups (RR 1.01, 95% CI 0.97-1.05)
Summary: Certainty of evidence is moderate to low; more research is needed with better quality trials to examine effectiveness of patching for large abrasions. Participants with patch took slightly longer to heal but the difference was small and possibly clinically insignificant.

Treatment

- same as corneal abrasion until re-epithelialization occurs
- topical hypertonic saline ointment at bedtime for 6-12 mo, topical lubrication
- bandage contact lens, anterior stromal puncture or phototherapeutic keratectomy for chronic recurrences

Corneal Ulcer

Etiology

- local necrosis of corneal tissue due to infection
 - infection is usually bacterial; rarely viral, fungal, or protozoan (*Acanthamoeba*)
- secondary to corneal exposure, abrasion, foreign body, contact lens use (50% of ulcers)
- also associated with conjunctivitis, blepharitis, keratitis, vitamin A deficiency

Clinical Features

- pain, photophobia, tearing, foreign body sensation, decreased VA (if central ulcer)
- corneal opacity that necroses and forms an excavated ulcer with infiltrative base
- overlying corneal epithelial defect that stains with fluorescein
- may develop corneal edema, conjunctival injection, anterior chamber cells/flare, hypopyon, corneal hypoesthesia (in viral keratitis)
- bacterial ulcers may have purulent discharge, viral ulcers may have watery discharge

Complications

- decreased vision, corneal perforation, iritis, endophthalmitis

Investigations

- Seidel test: fluorescein drop on the cornea under cobalt blue filter is used to detect leaking penetrating lesions; any aqueous leakage will dilute the green stain at site of wound

Treatment

- urgent referral to ophthalmology
- culture prior to treatment
- topical antibiotics every hour
- must treat vigorously to avoid complications

Table 7. Corneal Abrasion vs. Corneal Ulcer

	Abrasion	Ulcer
Time Course	Acute (instantaneous)	Subacute (days)
History of Trauma	Commonly	Rare
Cornea	Clear	White, necrotic area
Iris Detail	Clear	Obscured
Corneal Thickness	Normal	May have crater defect/thinning
Extent of Lesion	Limited to epithelium	Extension into stroma

Herpes Simplex Keratitis

- usually HSV type 1 (90% of population are carriers)
- may be triggered by stress, fever, sun exposure, immunosuppression

Clinical Features

- pain, tearing, foreign body sensation, red eye, may have decreased vision, eyelid edema
- corneal hypoesthesia
- classic form of HSV infectious epithelial keratitis is a dendritic (thin and branching) lesion with terminal end bulbs in epithelium that stains with fluorescein
- HSV may cause other forms of infectious epithelial keratitis, as well as stromal keratitis (which may be infectious or immune-mediated), and endotheliitis (presumably immune-mediated but possible role of live virus)

Complications

- corneal scarring (can lead to loss of vision)
- chronic interstitial keratitis due to penetration of virus into stroma
- secondary iritis, secondary glaucoma

Treatment

- topical antiviral such as trifluridine, or systemic antiviral such as acyclovir
- debridement of dendrite
- NO STEROIDS initially – may exacerbate condition
- ophthalmologist must exercise caution if adding topical steroids for stromal keratitis, endotheliitis or iritis, and patients covered with antiviral prophylaxis

Figure 13. Corneal abrasion vs. ulcer

Abrasion vs. Ulcer on Slit-Lamp
An abrasion appears clear while an ulcer is more opaque

Steroid treatment for ocular disorders should only be prescribed and supervised by an ophthalmologist, as they can impair corneal healing, exacerbate herpetic keratitis, and elevate IOP

Herpes Zoster Ophthalmicus

- dermatitis in the dermatomal distribution of CN V1 that is typically unilateral and respects the midline
- Hutchinson's sign: if tip of nose is involved (nasociliary branch of V1) then globe will be involved in ~75% of cases
- if no nasal involvement, eye is involved in 1/3 of patients

Clinical Features

- pain, tearing, photophobia, red eye
- corneal edema, pseudodendrite, SPK
- corneal hypoesthesia

Complications

- keratitis, ulceration, perforation and scarring
- secondary iritis, secondary glaucoma, cataract
- muscle palsies (rare) due to CNS involvement
- occasionally severe post-herpetic neuralgia

Treatment

- oral antiviral (acyclovir, valacyclovir, or famciclovir) immediately
- topical steroids, cycloplegia as indicated for immune-mediated keratitis, iritis
- erythromycin ointment if conjunctival involvement

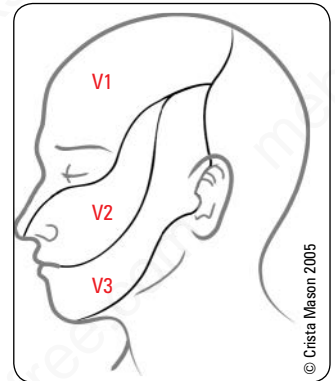

Figure 14. Trigeminal distribution

Keratoconus

- bilateral thinning and bulging (ectasia) of the cornea resulting in a conical shape
- usually sporadic but can be associated with Down's syndrome, atopy, contact lens use and vigorous eye rubbing
- associated with breaks in Descemet's membrane and Bowman's layer
- results in decreased vision from irregular astigmatism, scarring and stromal edema

Treatment

- attempt correction with spectacles and/or rigid gas permeable contact lens
- corneal collagen cross-linking treatment to halt disease progression
- intrastromal corneal ring segments can help flatten the corneal cone
- penetrating keratoplasty or deep anterior lamellar keratoplasty (partial-thickness corneal transplant) as last resort

To detect keratoconus, look for bulging of the lower eyelid when the patient looks downward (Munson's sign)

Arcus Senilis

- hazy white ring in peripheral cornea, <2 mm wide, clearly separated from limbus
- common, bilateral, benign corneal degeneration due to lipid deposition, part of the aging process
- may be associated with hypercholesterolemia if age <40 yr, check lipid profile
- no associated visual symptoms, complications or treatment necessary

Kayser-Fleischer Ring

- brown-yellow-green pigmented ring in peripheral cornea, starting inferiorly
- due to deposition of copper pigment in Descemet's membrane
- associated with Wilson's disease
- no associated symptoms or complications of ring
- treat underlying disease

The Uveal Tract

- uveal tract (from anterior to posterior) = iris, ciliary body, choroid
- vascularized, pigmented middle layer of the eye, between the sclera and the retina

Uveitis

- uveal inflammation which may involve one, two, or all three parts of the tract
- idiopathic or associated with autoimmune, infectious, granulomatous, malignant causes
- should be managed by an optometrist or ophthalmologist
- anatomically classified as anterior uveitis, intermediate uveitis, posterior uveitis, or panuveitis based on primary site of inflammation

Figure 15. Conjunctival hyperemia vs. ciliary flush

Table 8. Anatomic Classification of Uveitis

	Anterior Uveitis (Iritis)	Intermediate Uveitis	Posterior Uveitis
Location	Inflammation of iris, usually accompanied by cyclitis (inflammation of ciliary body), both = iridocyclitis Usually unilateral	The vitreous is the major site of the inflammation	Inflammation of the choroid and/or retina
Etiology	Usually idiopathic Connective tissue diseases: HLA-B27: reactive arthritis, ankylosing spondylitis, psoriatic arthritis, inflammatory bowel disease Non-HLA-B27: juvenile idiopathic arthritis Infectious: syphilis, Lyme disease, toxoplasmosis, TB, HSV, herpes zoster Other: sarcoidosis, trauma, large abrasion, post ocular surgery	Mostly idiopathic, secondary causes include sarcoidosis, Lyme disease, and multiple sclerosis	Bacterial: syphilis, tuberculosis Viral: herpes simplex virus, CMV in AIDS Fungal: histoplasmosis, candidiasis Parasitic: toxoplasmosis (most common cause), toxocara Immunosuppression may predispose to any of the above infections Autoimmune: Behçet's disease (triad of oral ulcers, genital ulcers, and posterior uveitis) Malignancies (masquerade syndrome): metastatic lesions, malignant melanoma
Clinical Features	Photophobia (due to reactive spasm of inflamed iris muscle), ocular pain, tenderness of the globe, brow ache (ciliary muscle spasm), decreased VA, lacrimation Ciliary flush (perilimbal conjunctival injection), miosis (spasm of sphincter muscle) Anterior chamber "cells" (WBC in anterior chamber due to anterior segment inflammation) and "flare" (protein precipitates in anterior chamber secondary to inflammation), hypopyon (collection of neutrophilic exudates inferiorly in the anterior chamber) Occasionally keratic precipitates (clumps of cells on corneal endothelium) Iritis typically reduces IOP because ciliary body inflammation causes decreased aqueous production; however, severe iritis, or iritis from herpes simplex and zoster may cause an inflammatory glaucoma (trabeculitis)	Insidious onset of blurred vision, accompanied by vitreous floaters Initial symptoms are usually unilateral but inflammatory changes are usually bilateral and asymmetric Associated with anterior uveitis, most severe cases of secondary intermediate uveitis Vitreous cells, condensations, and snowballs (vitreous aggregates of inflammatory cells) Posterior segment 'snowbank' = grey-white fibrovascular plaque at the pars plana	Painless as choroid has no sensory innervation Often no conjunctival or scleral injection present Decreased VA Floaters (debris and inflammatory cells) Vitreous cells and opacities Hypopyon formation
Complications	Inflammatory glaucoma Posterior synechiae Adhesions of posterior iris to anterior lens capsule Indicated by an irregularly shaped pupil If occurs 360°, can lead to angle closure glaucoma Peripheral anterior synechiae (rare): adhesions of iris to cornea → secondary angle closure glaucoma Cataracts Band keratopathy (with chronic iritis) Superficial corneal calcification keratopathy Macular edema with chronic iritis	Cystoid macular edema (30% of cases), cataract, and glaucoma	Macular edema Vitritis Neovascularization Visual field loss/scotoma
Treatment	Mydriatics: dilate pupil to prevent formation of posterior synechiae and to decrease pain from ciliary spasm Steroids: topical, sub-tenon, or systemic Systemic analgesia If recurrent episodes, extensive medical workup may be indicated to rule out secondary causes	Systemic or sub-tenon/intravitreal steroids and immunosuppressive agents Vitrectomy, cryotherapy, or laser photocoagulation to the "snowbank"	Steroids: sub-tenon, intravitreal, or systemic if indicated (e.g. threat of vision loss)

Lens

- consists of an outer capsule surrounding a soft cortex and a firm inner nucleus

Cataracts

- any opacity of the lens, regardless of etiology
- most common cause of reversible blindness worldwide
- types: nuclear sclerosis, cortical, posterior subcapsular

Etiology

- acquired
 - age-related (over 90% of all cataracts)
 - cataract associated with systemic disease (may have juvenile onset)
 - ♦ DM
 - ♦ metabolic disorders (e.g. Wilson's disease, galactosemia, homocystinuria)
 - ♦ hypocalcemia
 - traumatic (may be rosette shaped)
 - intraocular inflammation (e.g. uveitis)
 - toxic (steroids, phenothiazines)
 - radiation
- congenital
 - high myopia
 - present with altered red reflex or leukocoria
 - treat promptly to prevent amblyopia

Clinical Features

- gradual, painless, progressive decrease in VA
- glare, dimness, halos around lights at night, monocular diplopia
- "second sight" phenomenon: patient is more myopic than previously noted, due to increased refractive power of the lens (in nuclear sclerosis only)
 - patient may read without previously needed reading glasses
- diagnosis by slit-lamp exam
- may impair view of retina during funduscopy

Treatment

- medical: no role for medical management
- surgical: definitive treatment
 - indications for surgery
 - ♦ to improve visual function in patients whose vision loss leads to functional impairment
 - ♦ to aid management of other ocular disease (e.g. cataract that prevents adequate retinal exam or laser treatment of DR)
 - ♦ congenital or traumatic cataracts
 - phacoemulsification (phaco = lens)
 - ♦ most commonly used surgical technique
 - ♦ post-operative complications: RD, endophthalmitis, dislocated IOL, macular edema, glaucoma, posterior capsular opacification

Dislocated Lens (Ectopia Lentis)

Etiology

- associated with Marfan's Syndrome, Ehlers-Danlos type VI, homocystinuria, syphilis, lens coloboma (congenital cleft due to failure of ocular adnexa to complete growth)
- traumatic

Clinical Features

- decreased VA
- may get monocular diplopia
- iridodonesis (quivering of iris with movement)
- phacodonesis (observed movement of the lens)
- direct ophthalmoscopy may elicit abnormal red reflex

Complications

- cataract, glaucoma, uveitis

Treatment

- surgical lens replacement

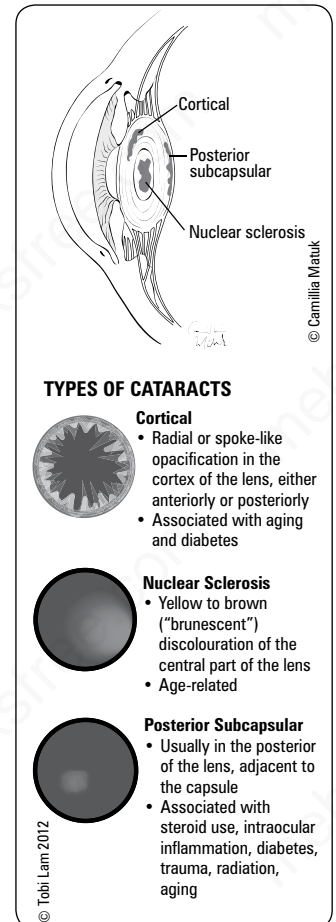

Figure 16. Types of cataracts

Vitreous

- clear gel (99% water plus collagen fibrils, glycosaminoglycans, and hyaluronic acid) that fills the posterior segment of eye
- normally adherent to optic disc, pars plana, and along major retinal blood vessels

Posterior Vitreous Detachment

Etiology

- central vitreous commonly shrinks and liquefies with age (syneresis)
- during syneresis, molecules that hold water condense causing vitreous floaters
- liquid vitreous moves between posterior vitreous gel and retina
- vitreous is peeled away and separates from the internal limiting membrane of the neurosensory retina posterior to the vitreous base

Clinical Features

- floaters, flashes of light

Complications

- traction at sites of firm adhesion may result in a retinal tear with or without subsequent rhegmatogenous retinal detachment
- retinal tears/detachment may cause vitreous hemorrhage if bridging retinal blood vessel is torn
- complications more common in high myopes and following ocular trauma (blunt or perforating)

Treatment

- acute onset of PVD requires a dilated fundus exam to rule out retinal tears/detachment
- no specific treatment available for floaters/flashes of light

Vitreous Hemorrhage

- bleeding into the vitreous cavity

Etiology

- PDR
- retinal tear/detachment
- PVD
- retinal vein occlusion
- trauma

Clinical Features

- sudden loss of VA
- may be preceded by "shower" of many floaters and/or flashes of light
- ophthalmoscopy: no red reflex if large hemorrhage, retina not visible due to blood in vitreous

Treatment

- ultrasound (B-scan) to rule out RD
- expectant: in non-urgent cases (e.g. no RD), blood usually resorbs in 3-6 mo
- surgical: vitrectomy ± RD repair ± retinal endolaser to possible bleeding sites/vessels

Endophthalmitis and Vitritis

- intraocular infection: acute, subacute, or chronic

Etiology

- most commonly a post-operative complication; risk following cataract surgery is <0.1%
- also due to penetrating injury to eye (risk is 3-7%), endogenous spread, and intravitreal injections
- etiology usually bacterial, may be fungal

Clinical Features

- painful, red eye, photophobia, discharge
- severely reduced VA, lid edema, proptosis, corneal edema, anterior chamber cells/flare, hypopyon, reduced red reflex
- may have signs of a ruptured globe (severe subconjunctival hemorrhage, hyphema, decreased IOP, etc.)

Treatment (see *Ocular Trauma*, OP39)

- **OCULAR EMERGENCY**: presenting vision best indicates prognosis
- LP or worse: admission, immediate vitrectomy, and intravitreal antibiotics to prevent loss of vision
- HM or better: vitreous tap for culture and intravitreal antibiotics
- topical fortified antibiotics

Weiss Ring: formed by glial tissue around the optic disc that remains attached to the detached posterior vitreous

Floaters: "bugs", "cobwebs", or "spots" of vitreous condensation that move with eye position

Although most floaters are benign, new or markedly increased floaters or flashes of light require a dilated fundus exam to rule out retinal tears/detachment

Any time a vitreous or retinal hemorrhage is seen in a child, must rule out child abuse

Remember to inquire about tetanus status in post-traumatic endophthalmitis

Retina

- composed of two parts (Figure 2)
 - neurosensory retina: comprises 9 of the 10 retinal layers, including the photoreceptors and the ganglion cell layer
 - retinal pigmented epithelium (RPE) layer: external to neurosensory retina
- macula: rich in cones (for colour vision); most sensitive area of retina
- fovea: centre of macula; responsible for detail, fine vision, lacks retinal vessels
- optic disc: collection of retinal nerve fibre layers forming optic nerve (CN2)
- ora serrata: irregularly-shaped, anterior margin of the retina (cannot be visualized with direct ophthalmoscope)

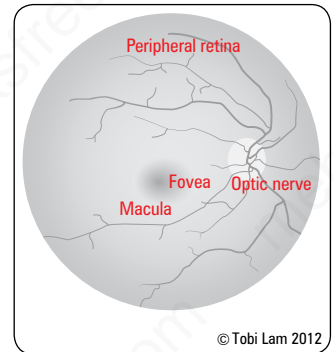

Figure 17. Retina

Central/Branch Retinal Artery Occlusion

Etiology

- occlusion of blood flow from following causes results in loss of vision due to oxygen starvation of the retinal tissues and eventual cell death
 - emboli from carotid arteries or heart (e.g. arrhythmia, endocarditis, valvular disease)
 - thrombus
 - temporal arteritis

Clinical Features

- sudden, painless (except in GCA), severe monocular loss of vision
- RAPD
- patient may have experienced transient episodes in the past (amaurosis fugax)
- funduscopy
 - “cherry-red spot”
 - retinal pallor
 - cotton wool spots (retinal infarcts)
 - cholesterol emboli (Hollenhorst plaques) – usually located at arteriole bifurcations

Treatment

- **OCULAR EMERGENCY:** attempt to restore blood flow within 2 h (irreversible retinal damage if >90 min of complete CRAO)
- massage the globe (compress eye with heel of hand for 10 s, release for 10 s, repeat for 5 min) to dislodge embolus
- decrease IOP
 - topical β -blockers
 - IV acetazolamide
 - IV mannitol (draws fluid from eye)
 - drain aqueous fluid – anterior chamber paracentesis (carries risk of infection, lens puncture)
- Nd:YAG laser embolectomy
- intra-arterial or intra-venous thrombolysis

Hallmark of CRAO

“Cherry-red spot” located at centre of macula (visualization of unaffected highly vascular choroid through the thin fovea)

Treatment for a central retinal artery occlusion (CRAO) must be initiated within 2 h of symptom onset for any hope of restoring vision

Central/Branch Retinal Vein Occlusion

- second most frequent “vascular” retinal disorder after DR
- usually a manifestation of a systemic disease (e.g. HTN, DM)
- thrombus occurs within the lumen of the central retinal vein/arteriovenous crossing point

Predisposing Factors

- arteriosclerotic vascular disease
- HTN
- DM
- glaucoma
- hyperviscosity (e.g. polycythemia rubra vera, sickle-cell disease, lymphoma, leukemia)
- drugs (e.g. oral contraceptive pill, diuretics)

Clinical Features

- painless, monocular, gradual or sudden vision loss
- \pm RAPD
- funduscopy
 - “blood and thunder” appearance
 - diffuse retinal hemorrhages, cotton wool spots, venous engorgement, swollen optic disc, macular edema
- two fairly distinct groups
 - venous stasis/non-ischemic retinopathy
 - ♦ no RAPD, VA ~20/80
 - ♦ mild hemorrhage, few cotton wool spots
 - ♦ resolves spontaneously over weeks to months
 - ♦ may regain normal vision if macula intact

The “blood and thunder” appearance on funduscopy is very specific for CRVO

There is an 8-10% risk of developing CRVO or BRVO in other eye

Intravitreal Aflibercept injection for Macular Edema Resulting from Central Retinal Vein Occlusion: One Year results of Phase 3 GALILEO study

Ophthalmology 2014; 121(11) 202-8

Treatment with intravitreal aflibercept provided significant functional and anatomic benefits after 52 weeks as compared with sham. The improvement achieved after 6 monthly doses at week 24 were maintained until week 52 with prn dosing.

- hemorrhagic/ischemic retinopathy
 - ♦ usually older patient with deficient arterial supply
 - ♦ RAPD, VA ~20/200, reduced peripheral vision
 - ♦ more hemorrhages, cotton wool spots, congestion
 - ♦ poor visual prognosis

Complications

- neovascularization of retina and iris (secondary rubeosis), leading to secondary glaucoma
- vitreous hemorrhage
- macular edema

Treatment

- treatment available for complications of CRVO/BRVO, including retinal laser photocoagulation, anti-VEGF and/or corticosteroid injection

Retinal Detachment

- cleavage in the plane between the neurosensory retina and the RPE
- three types
 - rhegmatogenous (most common)
 - ♦ caused by a tear or hole in the neurosensory retina, allowing fluid from the vitreous to pass into the subretinal space
 - ♦ tears may be caused by PVD, degenerative retinal changes, trauma, or iatrogenically
 - ♦ incidence increases with advancing age, in high myopes, and after ocular surgery/trauma
 - tractional
 - ♦ caused by vitreal, epiretinal, or subretinal membrane pulling the neurosensory retina away from the underlying RPE
 - ♦ found in conditions such as DR, CRVO, sickle cell disease, ROP, and ocular trauma
 - exudative
 - ♦ caused by damage to the RPE resulting in fluid accumulation in the subretinal space
 - ♦ main causes are intraocular tumours, posterior uveitis, central serous retinopathy

Clinical Features

- sudden onset
- flashes of light
 - due to mechanical stimulation of the retinal photoreceptors
- floaters
- hazy spots in the line of vision which move with eye position due to drops of blood from torn vessels bleeding into the vitreous
- curtain of blackness/peripheral field loss
 - darkness in one field of vision when the retina detaches in that area
- loss of central vision (if macula “off”)
- decreased IOP (usually 4-5 mmHg lower than the other, normal eye)
- ophthalmoscopy: detached retina is grey-white with surface blood vessels, loss of red reflex
- ± RAPD

Treatment

- prophylactic: symptomatic tear (flashes or floaters) can be sealed off with laser/cryotherapy
- therapeutic
 - rhegmatogenous
 - ♦ scleral buckle procedure
 - ♦ pneumatic retinopexy
 - ♦ vitrectomy plus injection of gas (injection of silicone oil in cases of recurrent detachment)
 - tractional
 - ♦ vitrectomy ± membrane removal/scleral buckling/injection of intraocular gas or silicone oil as necessary
 - exudative
 - ♦ management is nonsurgical; any underlying disease should be treated if possible

Complications

- loss of vision, vitreous hemorrhage, recurrent RD
- a RD is an emergency, especially if the macula is still attached (macula “on”)
- prognosis for visual recovery varies inversely with the amount of time the retina is detached and whether the macula is attached or not

Retinitis Pigmentosa

- hereditary degenerative disease of the retina manifested by rod > cone photoreceptor degeneration and retinal atrophy
- many forms of inheritance, most commonly autosomal recessive (60%)

Efficacy and Safety of Widely Used Treatments for Macular Edema Secondary to Retinal Vein Occlusion: A Systematic Review

BMC Ophthalmol 2014;14:7

Purpose: To assess the efficacy of widely used treatments for macular edema (ME) secondary to retinal vein occlusion (RVO). ME secondary to RVO can cause vision loss due to blockage of the central retinal vein (CRVO) or a branch retinal vein (BRVO).

Outcomes: Mean change in best corrected visual acuity (BCVA) from baseline and/or number of patients gaining at least 10 letters from baseline to 6 mo or equivalent time point.

Results: 14 unique RCTs identified. Ranibizumab 0.5 mg produced greater improvements in BCVA at 6 mo compared to sham in BRVO (mean difference 11 letters; 95% CI 7.83-14.17) and CRVO (mean difference 14 letters; 95% CI 10.51-17.69). Improvements in BCVA were also observed with dexamethasone intravitreal implant (IVI) 0.7 mg compared with sham in patients with BRVO or CRVO (mean difference 2.5 letters; 95% CI 0.7-4.3). The difference was significant with BRVO alone, but not CRVO alone. At 36 mo in a large prospective RCT, a greater proportion of patients with BRVO gained >15 letters with laser therapy versus no treatment (OR 3.16; 95% CI 1.25-8.00), whereas no difference was observed in a 9 mo endpoint smaller study. Three studies showed no benefit for laser therapy in CRVO.

Conclusions: Both ranibizumab and dexamethasone IVI show significant improvements over previously accepted standard of care (laser therapy) for the treatment of BRVO and CRVO.

Superotemporal retina is the most common site for horseshoe tears

Clinical Features

- night blindness, decreased peripheral vision (“tunnel vision”), decreased central vision (macular changes), glare (from posterior subcapsular cataracts; common)

Investigations

- funduscopy: areas of “bone-spicule” pigment clumping in mid-periphery of retina, narrowed retinal arterioles, pale optic disc
- electrophysiological tests: electroretinography (ERG) and electrooculography (EOG) assist in diagnosis

Treatment

- no treatments available to reverse the condition; cataract extraction improves visual function; vitamin A and vitamin E supplementation can reduce progression of disease in some patients

Retinitis Pigmentosa Inherited Forms

- Autosomal recessive: most common
- Autosomal dominant: best prognosis
- X-linked: worst prognosis

Triad of Retinitis Pigmentosa

APD

- Arteriolar narrowing
- Perivascular bony-spicule pigmentation
- Optic disc pallor

Age-Related Macular Degeneration

- leading cause of irreversible blindness in the Western world, associated with increasing age, usually bilateral but asymmetric

Classification

- **Non-Exudative/“Dry” (Non-Neovascular) AMD**
 - most common type of AMD (90% of cases)
 - slowly progressive loss of visual function
 - drusen: yellow-white deposits between the RPE and Bruch’s membrane (area separating inner choroidal vessels from RPE)
 - geographic RPE atrophy: coalescence of depigmented RPE, clumps of focal hyperpigmentation or hypopigmentation
 - may progress to neovascular AMD
- **Exudative/“Wet” (Neovascular) AMD**
 - 10% of AMD, but 80% of AMD that results in severe vision loss
 - choroidal neovascularization: drusen predisposes to breaks in Bruch’s membrane, causing subsequent growth and proliferation of new, fine choroidal vessels
 - may lead to: serous detachment of overlying RPE and retina, hemorrhage and lipid precipitates into the subretinal space
 - can also lead to an elevated subretinal mass due to fibrous metaplasia of hemorrhagic RD, causing disciform scarring and severe central vision loss

Risk Factors

- female
- increasing age
- family history
- smoking
- Caucasian race
- blue irides

Clinical Features

- variable degree of progressive central vision loss
- metamorphopsia (distorted vision characterized by straight parallel lines appearing convergent or wavy) due to macular edema

Investigations

- Amsler grid: held at normal reading distance with glasses on, assesses macular function
- fluorescein angiography: assess type and location of choroidal neovascularization – pathologic new vessels leak dye
- OCT retinal imaging

Treatment

- non-neovascular “dry” AMD
 - monitor, Amsler grid allows patients to check for metamorphopsia
 - low vision aids (e.g. magnifiers, closed-circuit television)
 - anti-oxidants, green leafy vegetables
 - sunglasses/visors
 - see Age-related Eye Disease Study 2 (AREDS2) in sidebar
- neovascular “wet” AMD
 - see *Common Medications, OP42*
 - intravitreal injection of anti-VEGF
 - ♦ pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®), aflibercept (Eylea®) (see *VEGF Inhibitors, OP43*)
 - laser photocoagulation for neovascularization
 - no definitive treatment for disciform scarring
 - photodynamic therapy with verteporfin (Visudyne®)
 - ♦ IV injection of verteporfin, followed by low intensity laser to area of choroidal neovascularization

Age-Related Eye Disease Study 2 (AREDS2)

Lutein + zeaxanthin and omega-3 fatty acids for AMD: the Age-Related Eye Disease Study 2 (AREDS2) randomized clinical trial. *JAMA* 2013 May 15;309(19):2005-2015

The original AREDS formulation contains vitamin C, E and beta-carotene, zinc and copper; reduced risk of progression to advanced AMD by 2%. Addition of lutein+zeaxanthin, DHA+EPA, or both to the AREDS formulation in primary analyses didn’t reduce risk of progression to advanced AMD. However, because of the potential increased incidence of lung cancer in former smokers, lutein+zeaxanthin could be an appropriate carotenoid substitute in the AREDS formulation.

Glaucoma

Definition

- progressive, pressure-sensitive, optic neuropathy involving characteristic structural changes to optic nerve head with associated visual field changes
- commonly associated with high IOP, but not required for diagnosis

Background

- aqueous is produced by the ciliary body and drains into the episcleral veins via the trabecular meshwork and the Canal of Schlemm
- an isolated increase in IOP is termed ocular hypertension (OHT) - should be followed for increased risk of developing glaucoma
- pressures > 21 mmHg increase the risk of developing glaucoma
- loss of peripheral vision most commonly precedes central vision loss
- structural changes commonly precede functional changes

Investigations

- VA testing
- slit-lamp exam to assess anterior chamber depth; gonioscopy lens to assess angle patency
- ophthalmoscopy to assess the disc features
- tonometry to measure IOP
- visual field testing
- pachymetry to measure corneal thickness
- follow-up includes optic disc examination, IOP measurement, and visual field testing to monitor course of disease

Ten Year Follow-Up of Age-Related Macular Degeneration in the Age-Related Eye Disease Study: AREDS Report No. 36

JAMA Ophthalmol 2014 Mar;132(3):272-7

Study: Randomized clinical trial.

Objective: To describe 10 yr progression rates to intermediate or advanced AMD.

Patients: Age-related eye disease study (AREDS) participants were observed for an additional 5 yr after RCT completion. Participants aged 55-80 yr with no AMD or AMD of varying severity (n = 4,757) were followed up in the AREDS trial for a median duration of 6.5 yr. When the trial ended, 3,549 of the 4,203 surviving participants were followed for 5 additional yr.

Intervention: Treatment with antioxidant vitamins and minerals.

Main Outcome: Development of varying stages of AMD and changes in visual acuity.

Results: The risk of progression to advanced AMD increased with increasing age (p=0.01) and severity of drusen. Women (p=0.005) and current smokers (p<0.001) were at increased risk of neovascular AMD. In the oldest participants with the most severe AMD status at baseline, the risks of developing neovascular AMD and central geographic atrophy by 10 yr were 48.1% and 26.0%, respectively. Similarly, rates of progression to large drusen increased with increasing severity of drusen at baseline, with 70.9% of participants with bilateral medium drusen progressing to large drusen and 13.8% to advanced AMD in 10 yr. Median visual acuity at 10 yr in eyes that had large drusen at baseline but never developed advanced AMD was 20/25; eyes that developed advanced AMD had a median visual acuity of 20/200.

Conclusion: The natural history of AMD demonstrates relentless loss of vision in persons who developed advanced AMD.

Average IOP = 15 ± 3 mmHg

Normal C:D ≤0.4

Suspect glaucoma if C:D ratio >0.6, C:D ratio differs between eyes by >0.2, or cup approaches disc margin

Figure 18. Glaucomatous damage

Figure 19. Aqueous flow and sites of potential resistance

Primary Open-Angle Glaucoma

- most common form, >95% of all glaucoma cases
- within the trabecular meshwork and the Canal of Schlemm
- insidious and asymptomatic, screening is critical for early detection

Major Risk Factors

- ocular hypertension (IOP >21 mmHg)
- age: prevalence at 40 yr is 1-2% and at 80 yr is 10%
- ethnicity: African descent
- familial (2-3x increased risk); polygenic
- thin central cornea (OHTS trial)

Minor Risk Factors

- myopia
- HTN
- DM
- hyperthyroidism (Graves' disease)
- chronic topical ophthalmic steroid use in steroid responders – yearly eye exams recommended if >4 wk of steroid use
- previous ocular trauma
- anemia/hemodynamic crisis (ask about blood transfusions in past)

Clinical Features

- asymptomatic initially
- insidious, painless, gradual rise in IOP due to restriction of aqueous outflow
- bilateral, but usually asymmetric
- earliest signs are optic disc changes
 - increased C:D ratio (vertical C:D >0.6)
 - significant C:D asymmetry between eyes (>0.2 difference)
 - thinning, notching of the neuroretinal rim
 - flame shaped disc hemorrhage
 - 360° of peripapillary atrophy
 - nerve fibre layer defect
 - large vessels become nasally displaced
- visual field loss
- slow, progressive, irreversible loss of peripheral vision
- paracentral defects, arcuate scotoma, and nasal step are characteristics (Figure 19)
- late loss of central vision if untreated

Treatment

- medical treatment: decrease IOP by increasing the drainage and/or decreasing the production of aqueous (see *Glaucoma Medications, Table 14, OP42*)
 - increase aqueous outflow
 - ♦ topical cholinergics
 - ♦ topical prostaglandin analogues
 - ♦ topical α -adrenergics
 - decrease aqueous production
 - ♦ topical β -blockers
 - ♦ topical and oral carbonic anhydrase inhibitor
 - ♦ topical α -adrenergics
- laser trabeculoplasty, cyclophotocoagulation in order to achieve selective destruction of ciliary body (for refractory cases)
- trabeculectomy: creation of a new outflow tract from anterior chamber to under conjunctiva forming a bleb
- minimally invasive glaucoma surgery (MIGS): implantation of IOP lowering drainage devices (e.g. iStent) through an ab interno microincisional approach
- serial optic nerve head examinations, IOP measurements, and visual field testing to monitor disease course

Risk Factors for POAG

A FIAT

- Age
- Family history
- IOP
- African descent
- Thin cornea

Open- and Closed-Angle Glaucoma

POAG

- Common (95%)
- Chronic course
- Painless eye without redness
- Moderately \uparrow IOP
- Normal cornea and pupil
- No N/V
- No halos around light

PACG

- Rare (5%)
- Acute onset
- Painful red eye
- Extremely \uparrow IOP
- Hazy cornea
- Mid-dilated pupil unreactive to light
- \pm N/V, abdominal pain
- Halos around light

Elevated IOP is the only modifiable risk factor that has been proven to prevent progression of glaucoma. Treatment of patients with ocular hypertension but no signs of glaucoma also benefit from a reduction in risk of development of glaucoma

The Ocular Hypertension Treatment Study

Arch Ophthalmol-Chic 2002;120:701-713

Study: Randomized clinical trial.

Patients: 1,636 patients with no evidence of glaucomatous damage, aged 40-80 yr, and with IOP between 24-32 mmHg in one eye and between 21-32 mmHg in the other eye.

Intervention: Randomized to observation or treatment with commercially available topical ocular hypotensive medication.

Main Outcome: Development of visual field abnormality or optic disc deterioration attributed to POAG.

Results: Mean reduction in IOP in the medication group was $22.5\% \pm 9.9\%$ vs. $4.0\% \pm 11.6\%$ in the observation group. At 5 yr, the probability of developing POAG was 4.4% in the medication group and 9.5% in the observation group ($p < 0.0001$).

Conclusions: Topical ocular hypotensive medication was effective in delaying or preventing the onset of POAG in individuals with elevated IOP.

Normal Tension Glaucoma

- POAG with IOP in normal range
- often found in women >60 yr, but may occur earlier
- associated with migraines, peripheral vasospasm, systemic nocturnal hypotension, sleep apnea
- damage to optic nerve may be due to vascular insufficiency

Treatment

- treat reversible causes

Secondary Open Angle Glaucoma

- increased IOP secondary to ocular/systemic disorders that obstruct the trabecular meshwork
 - steroid-induced glaucoma
 - traumatic glaucoma
 - pigmentary dispersion syndrome
 - pseudoexfoliation syndrome

Primary Angle-Closure Glaucoma

- 5% of all glaucoma cases
- peripheral iris bows forward obstructing aqueous access to the trabecular meshwork
- sudden forward shift of the lens-iris diaphragm causes pupillary block and results in impaired drainage, leading to a sudden rise in IOP

Risk Factors

- hyperopia: small eye, big lens – large lens crowds the angle
- age >70 yr
- female
- family history
- more common in people of Asian and Inuit descent
- mature cataracts
- shallow anterior chamber
- pupil dilation (topical and systemic anticholinergics, stress, darkness)

Clinical Features

- red, painful eye = **RED FLAG**
- unilateral, but other eye at increased risk
- decreased visual acuity, vision acutely blurred from corneal edema
- halos around lights
- nausea and vomiting, abdominal pain
- fixed, mid-dilated pupil
- marked increase in IOP; may be noticeable even to palpation (>40 mmHg)
- shallow anterior chamber ± cells in anterior chamber

Complications

- irreversible loss of vision within hours to days if untreated
- permanent peripheral anterior synechiae, resulting in permanent angle closure

Treatment

- OCULAR EMERGENCY:** refer to ophthalmologist for acute angle closure glaucoma
 - aqueous suppressants and hyperosmotic agents
- medical treatment (see *Glaucoma Medications, Table 14, OP42*)
 - miotic drops (pilocarpine) to reverse pupillary block
 - multiple topical IOP-lowering agents
 - hyperosmotic agents such as oral glycerine, or IV mannitol
- laser iridotomy is definitive

Secondary Angle-Closure Glaucoma

Uveitis

- inflamed iris adheres to lens (posterior synechiae)

Neovascular Glaucoma

- abnormal blood vessels develop on surface of iris (rubeosis iridis), in the angle, and within the trabecular meshwork
- due to retinal ischemia associated with PDR or CRVO
- treatment with laser therapy to retina reduces neovascular stimulus to iris and angle vessels

Rule of Fours

1/4 of general population using topical steroid for 4 wk, 4 x/d will develop an increase in IOP

Figure 20. Normal open angle vs. angle-closure glaucoma

Angle Closure Glaucoma BACH

Hyperosmotic agents

Collaborative Normal Tension Glaucoma Study *Curr Opin Ophthalmol* 2003;14:86-90

Treatment aimed at lowering IOP by 30% in patients with normal tension glaucoma tends to reduce the rate of visual field loss. Due to variability in disease progression and a significant group that shows no visual field loss at 5 yr despite no treatment, further studies are needed to delineate which subgroups may benefit most from treatment.

Pupils

- pupil size is determined by the balance between the sphincter muscle and the dilator muscle
- sphincter muscle is innervated by the parasympathetic nervous system carried by CN III
- dilator muscle is innervated by the sympathetic nervous system (SNS)
 - first order neuron = hypothalamus → brainstem → spinal cord
 - second order/preganglionic neuron = spinal cord → sympathetic trunk via internal carotid artery → superior cervical ganglion in neck
 - third order/postganglionic fibres originate in the superior cervical ganglion, neurotransmitter is norepinephrine
 - ♦ as a diagnostic test, 4-10% cocaine prevents the re-uptake of norepinephrine, and will cause dilation of normal pupil, but not one with loss of sympathetic innervation (Horner's Syndrome)
- see [Neurology, Figure 8, N8](#)

5 Targets of Retinal Signals

- Pre-tectal nucleus (pupillary reflex/eye movements)
- Lateral geniculate body of thalamus
- Superior colliculus (eye movements)
- Suprachiasmatic nucleus (optokinetic)
- Accessory optic system (circadian rhythm)

Pupillary Light Reflex

- light shone directly into eye travels along optic nerve (CN II, afferent limb) → optic tracts → bilateral midbrain
- impulses enter bilaterally in midbrain via pretectal area and Edinger-Westphal nuclei
- nerve impulses then travel down CN III (efferent limb) bilaterally to reach the ciliary ganglia, and finally to the iris sphincter muscle, which results in the direct and consensual light reflexes

$\alpha 1$ – Pupillary dilator muscle contraction (Mydriasis)

$\beta 2$ – Ciliary muscle relaxation (Non-accommodation); increased aqueous humour production

M3 – Pupillary sphincter contraction (Miosis); increased ciliary muscle contraction (Accommodation)

Pupil Abnormalities

Denervation Hypersensitivity

- when post-ganglionic fibres are damaged, the understimulated end-organ attempts to compensate by developing an excess of neuroreceptors and becomes hypersensitive
- postganglionic parasympathetic lesions (i.e. Adie's pupil)
 - pupil will constrict with 0.125% pilocarpine (cholinergic agonist), normal pupil will not
- postganglionic sympathetic lesions (this test is used to differentiate between pre- and post-ganglionic lesions in Horner's syndrome)
 - pupil will dilate with 0.125% epinephrine, normal pupil will not

Local Disorders of Iris

- posterior synechiae (adhesions between iris and lens) due to iritis can present as an abnormally shaped pupil
- ischemic damage (e.g. post-acute angle-closure glaucoma) usually occurs at 3 and 9 o'clock positions resulting in a vertically oval pupil that reacts poorly to light
- trauma (e.g. post-intraocular surgery)

Anisocoria

- unequal pupil size
- idiopathic/physiologic anisocoria
 - 20% of population
 - round, regular, <1 mm difference
 - pupils reactive to light and accommodation
 - responds normally to mydriatics/miotics
 - post eye surgery
- see [Table 9](#) for other causes of anisocoria

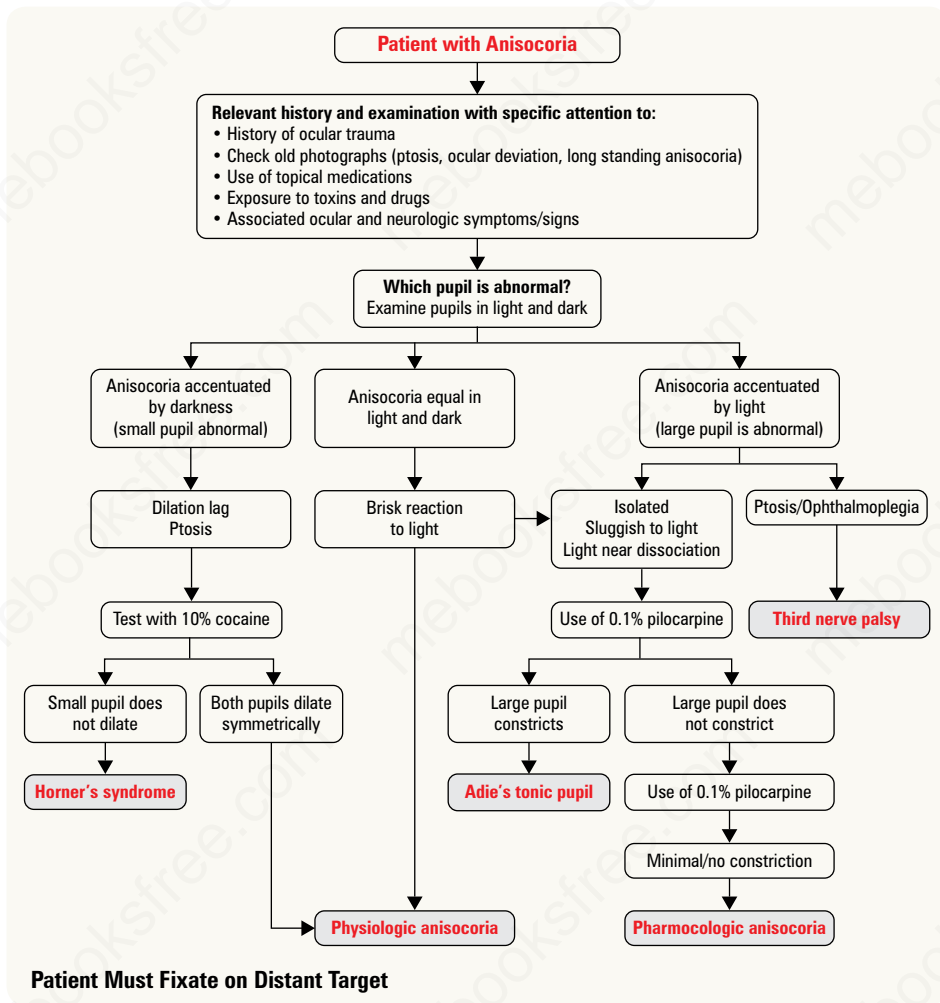

Figure 21. Approach to anisocoria

Reproduced with permission from: Kedar S, Biouesse V, Newman NJ. Approach to the patient with anisocoria. In: UpToDate, Rose, BD (editor), UpToDate, Waltham, MA, 2011. Copyright 2011 UpToDate, Inc. For more information visit www.uptodate.com.

Table 9. Summary of Conditions Causing Anisocoria

Features	Site of Lesion	Light and Accommodation	Anisocoria	Mydriatics/Miotics	Effect of Pilocarpine
ABNORMAL MIOTIC PUPIL (impaired pupillary dilation)					
Argyll-Robertson Pupil	Irregular, usually bilateral	Midbrain	Poor in light; better to accommodation	Dilates/Constricts	
Horner's Syndrome	Round, unilateral, ptosis, anhidrosis, pseudoenophthalmos	Sympathetic system	Both brisk	Greater in dark	Dilates/Constricts
ABNORMAL MYDRIATIC PUPIL (impaired pupillary constriction)					
Adie's Tonic Pupil	Irregular, larger in bright light	Ciliary ganglion	Poor in light, better to accommodation	Greater in light	Dilates/Constricts Constricts (hypersensitivity to dilute pilocarpine)
CN III Palsy	Round	Superficial CN III	± fixed (acutely) at 7-9 mm	Greater in light	Dilates/Constricts Constricts
Mydriatic Pupil	Round, uni- or bilateral	Iris sphincter	Fixed at 7-8 mm	Greater in light	No effect Will not constrict

Dilated Pupil (Mydriasis)

Sympathetic Stimulation

- fight or flight response
- mydriatic drugs: epinephrine, dipivefrin (Propine®), phenylephrine

Parasympathetic Understimulation

- cycloplegics/mydriatics: atropine, tropicamide, cyclopentolate (parasympatholytic)
- CN III palsy
 - eye deviated down and out with ptosis present
 - etiology includes stroke, neoplasm, aneurysm, acute rise in ICP, DM (may spare pupil), trauma
 - both mydriatics and CN III palsy cause pupil dilation; however, pupils in CN III palsy will constrict briskly to pilocarpine, while pupils dilated from mydriatics will not

Acute Angle-Closure Glaucoma

- fixed, mid-dilated pupil

Adie's Tonic Pupil

- 80% unilateral, F>M
- pupil is tonic or reacts poorly to light (both direct and consensual) but constricts with accommodation
- caused by benign lesion in ciliary ganglion; results in denervation hypersensitivity of parasympathetically innervated constrictor muscle
 - dilute (0.125%) solution of pilocarpine will constrict tonic pupil but have no effect on normal pupil
- long-standing Adie's pupils are smaller than unaffected eye

Trauma

- damage to iris sphincter from blunt or penetrating trauma
- iris transillumination defects may be apparent using ophthalmoscope or slit-lamp
- pupil may be dilated (traumatic mydriasis) or irregularly shaped from tiny sphincter ruptures

Constricted Pupil (Miosis)

Senile Miosis

- decreased sympathetic stimulation with age

Parasympathetic Stimulation

- local or systemic medications such as:
 - cholinergic agents: pilocarpine, carbachol
 - cholinesterase inhibitor: phospholine iodide
 - opiates, barbiturates

Horner's Syndrome

- lesion in sympathetic pathway
- difference in pupil size greater in dim light, due to decreased innervation of adrenergics to iris dilator muscle
- associated with ptosis, anhidrosis of ipsilateral face/neck
- application of cocaine 4-10% (blocks reuptake of norepinephrine) to eye does not result in pupil dilation (vs. physiologic anisocoria), therefore confirms diagnosis
- hydroxyamphetamine 1% (stimulates norepinephrine release) will dilate pupil if central or preganglionic lesion, not postganglionic lesion
- postganglionic lesions result in denervation hypersensitivity, which will cause pupil to dilate with 0.125% epinephrine, whereas normal pupil will not
- causes: carotid or subclavian aneurysm, brainstem infarct, demyelinating disease, cervical or mediastinal tumour, Pancoast tumour, goitre, cervical lymphadenopathy, surgical sympathectomy, Lyme disease, cervical ribs, tabes dorsalis, cervical vertebral fractures

Iritis

- miotic pupil initially
- later, may be irregularly shaped pupil due to posterior synechiae
- later stages non-reactive to light

Argyll-Robertson Pupil

- both pupils irregular and <3 mm in diameter, ± ptosis
- does not respond to light stimulation
- responds to accommodation (light-near dissociation)
- suggestive of neurosyphilis or other conditions (DM, encephalitis, MS, chronic alcoholism, CNS degenerative diseases)

Other Causes

- optic neuritis, retinal lesions

CN III palsy with pupillary involvement may be associated with a posterior communicating artery aneurysm

Figure 22. CN III lesions with and without mydriasis

Horner's MAP
Miosis
Anhidrosis
Ptosis

Relative Afferent Pupillary Defect

Figure 23. Relative afferent pupillary defect

- also known as Marcus Gunn pupil
- impairment of direct pupillary response to light, caused by a lesion in visual afferent (sensory) pathway anterior to optic chiasm
- differential diagnosis: large RD, BRAO, CRAO, CRVO, advanced glaucoma, optic nerve compression, optic neuritis (most common)
- does not occur with media opacity (e.g. corneal edema, cataracts)
- pupil reacts poorly to light and better to accommodation
- test: swinging flashlight
 - if light is shone in the affected eye, direct and consensual response to light is decreased
 - if light is shone in the unaffected eye, direct and consensual response to light is normal
 - if the light is moved quickly from the unaffected eye to the affected eye, “paradoxical” dilation of both pupils occurs
 - observe red reflex, especially in patients with dark irides
- if the defect is bilateral there is no RAPD, as dilation is measured relative to the other eye

Cataracts never produce an RAPD

It is possible to have RAPD and normal vision at the same time, e.g. in damaged superior colliculus caused by thalamic hemorrhage

Differentiate RAPD from physiologic pupillary athetosis (“hippus”), which is rapid, rhythmic fluctuations of the pupil, with equal amplitude in both eyes

Malignancies

- uncommon site for 1° malignancies
- see *Retinoblastoma*, OP38

Lid Carcinoma

Etiology

- basal cell carcinoma (rodent ulcer) (90%)
 - spread via local invasion, rarely metastasizes
 - ulcerated centre, indurated base with pearly rolled edges, telangiectasia
- squamous cell carcinoma (<5%)
 - spread via local invasion, may also spread to nodes and metastasize
 - ulceration, keratosis of lesion
- sebaceous cell carcinoma (1-5%)
 - often masquerades as chronic blepharitis or recurrent chalazion
 - highly invasive, metastasize
- Kaposi’s sarcoma, malignant melanoma, Merkel cell tumour, metastatic tumour

Treatment

- incisional or excisional biopsies
- may require cryotherapy, radiotherapy, chemotherapy, immunotherapy
- surgical reconstruction

Uveal Melanoma

- most common 1° intraocular malignancy in adults
- more prevalent in Caucasians
- arise from uveal tract, 90% choroidal melanoma
- hepatic metastases predominate

Clinical Features

- classic appearance of a pigmented dome-shaped mass extending from the ciliary body or the choroid
- diagnosis necessitates expertise of an ophthalmologist/ocular oncologist

Treatment

- imaging to investigate spread
- depending on the size of the tumour, either radiotherapy, enucleation, limited surgery

Metastases

- most common intraocular malignancy in adults
- most commonly from breast and lung in adults, neuroblastoma in children
- usually infiltrate the choroid, but may also affect the optic nerve or extraocular muscles
- may present with decreased or distorted vision, irregularly shaped pupil, iritis, hyphema

Treatment

- local radiation, chemotherapy
- enucleation if blind, painful eye

Ocular Manifestations of Systemic Disease**HIV/AIDS**

- up to 75% of patients with AIDS have ocular manifestations

External Ocular Signs

- Kaposi's sarcoma
 - secondary to human herpes virus 8 (HHV-8), affects conjunctiva of lid or the globe
 - differential diagnosis: subconjunctival hemorrhage (non-clearing), hemangioma
- multiple molluscum contagiosum
- herpes simplex/zoster keratitis

Retina

- HIV retinopathy (most common)
 - cotton wool spots in >50% of HIV patients
 - intraretinal hemorrhage
- CMV retinitis
 - ocular opportunistic infection developed when severely immunocompromised (CD4 count ≤ 50)
 - a necrotizing retinitis, with retinal hemorrhage and vasculitis, "brushfire" or "pizza pie" appearance
 - presents with scotomas (macular involvement and RD), blurred vision, and floaters
 - untreated infection will progress to other eye in 4-6 wk
 - treatment: virostatic agents (e.g. gancyclovir or foscarnet) via IV or intravitreal injection
- necrotizing retinitis
 - from herpes simplex virus, herpes zoster, toxoplasmosis
 - disseminated choroiditis
 - *Pneumocystis carinii*, *Mycobacterium avium intracellulare*, *Candida*

Other Systemic Infections

- herpes zoster
 - see *Herpes Zoster*, OP18
- candidal endophthalmitis
 - fluffy, white-yellow, superficial retinal infiltrate that may eventually result in vitritis
 - may present with inflammation of the anterior chamber
 - treatment: systemic amphotericin B, oral fluconazole

**To Find Small Ocular Melanoma****TFSOM**

T – Thickness > 2mm

F – Subretinal Fluid

S – Symptoms – Vision changes

O – Orange pigment

M – Margin within 3 mm of optic disc

- toxoplasmosis
 - focal, grey-yellow-white, chorioretinal lesions with surrounding vasculitis and vitreous infiltration (vitreous cells)
 - can be congenital (transplacental) or acquired (caused by *Toxoplasma gondii* protozoa transmitted through raw meat and cat feces)
 - congenital form more often causes visual impairment (more likely to involve the macula)
 - treatment: pyrimethamine, sulfonamide, folinic acid, or clindamycin. Consider adding steroids if severe inflammation (vitritis, macular or optic nerve involvement)

Diabetes Mellitus

- most common cause of blindness in young people in North America
- loss of vision due to:
 - progressive microangiopathy leading to macular edema
 - progressive DR → neovascularization → traction → RD and vitreous hemorrhage
 - rubeosis iridis (neovascularization of the iris) leading to neovascular glaucoma (poor prognosis)
 - macular ischemia

DIABETIC RETINOPATHY

Background

- altered vascular permeability (loss of pericytes, breakdown of blood-retinal barrier, thickening of basement membrane)
- predisposition to retinal vessel obstruction (CRAO, CRVO, and BRVO)

Classification

- non-proliferative: increased vascular permeability and retinal ischemia
 - microaneurysms
 - dot and blot hemorrhages
 - hard exudates (lipid deposits), non-specific for DR
 - macular edema
- advanced non-proliferative (or pre-proliferative)
 - non-proliferative findings plus:
 - ◆ venous beading (in ≥ 2 of 4 retinal quadrants)
 - ◆ intraretinal microvascular anomalies (IRMA) in 1 of 4 retinal quadrants
 - IRMA: dilated, leaky vessels within the retina
 - ◆ cotton wool spots (nerve fibre layer infarcts)
- proliferative
 - 5% of patients with DM will reach this stage
 - neovascularization of iris, disc, retina
 - ◆ neovascularization of iris (rubeosis iridis) can lead to neovascular glaucoma
 - ◆ vitreous hemorrhage, bleeding from fragile new vessels, fibrous tissue can contract causing tractional RD
 - may remain asymptomatic well beyond stage of optimal treatment
 - high risk of severe vision loss secondary to vitreous hemorrhage, RD

Screening Guidelines for Diabetic Retinopathy

- type 1 DM
 - screen for retinopathy beginning annually 5 yr after disease onset
 - annual screening indicated for all patients over 12 yr and/or entering puberty
- type 2 DM
 - initial examination at time of diagnosis, then annually
- pregnancy
 - ocular exam in 1st trimester, close follow-up throughout as pregnancy can exacerbate DR
 - gestational diabetics are not at risk for DR

Treatment

- Diabetic Control and Complications Trial (DCCT)
 - tight control of blood sugar decreases frequency and severity of microvascular complications
- blood pressure control
- focal laser for clinically significant macular edema
- intravitreal injection of corticosteroid or anti-VEGF for fovea-involved diabetic macular edema
- pan-retinal laser photocoagulation for PDR: reduces neovascularization, hence reducing the angiogenic stimulus from ischemic retina by decreasing retinal metabolic demand → reduces risk of blindness
- vitrectomy for non-clearing vitreous hemorrhage and tractional RD in PDR
- vitrectomy before vitreous hemorrhage does not improve the visual prognosis

Lens Changes

- earlier onset of senile nuclear sclerotic and cortical cataracts
- may get hyperglycemic cataract due to sorbitol accumulation (rare)
- changes in blood glucose levels (poor control) can suddenly cause refractive changes by 3-4 diopters

Macular edema is the most common cause of visual loss in patients with background DR

Expanded 2 Year Follow-Up of Ranizumab Plus Prompt or Deferred Laser or Triamcinolone Plus Prompt Laser for Diabetic Macular Edema

Ophthalmology 2011;118:609-614
Ranibizumab (Lucentis®) with prompt or deferred laser is more effective than intravitreal corticosteroid injections + laser or laser alone with sustained efficacy up to 24 mo.

Clinically significant macular edema is defined as thickening of the retina at or within 500 μm of the centre of the macula

Presence of DR in Type 1 DM

- 25% after 5 yr
- 60% after 10 yr
- >80% after 15 yr

Type 2 DM

- 20% at time of diagnosis
- 60% after 20 yr

Intravitreal Aflibercept for Diabetic Macular Edema

Ophthalmology 2014;121:2247-54
At 52 weeks, intravitreal aflibercept demonstrated significant superiority in functional and anatomic endpoints over laser with similar efficacy in the 2mg q4wks and 2mg q8wks group.

Extraocular Muscle Palsy

- usually CN III infarct
- pupil usually spared in diabetic CN III palsy, but ptosis is observed
- may involve CN IV and VI
- usually recover within few months

Optic Neuropathy

- visual acuity loss due to infarction of optic disc/nerve

Figure 24. DM vs. HTN retinopathy

Aflibercept, Bevacizumab, or Ranibizumab for Diabetic Macular Edema: 2 Year Result from a Comparative Effectiveness Randomized Clinical Trial

Ophthalmology 2016; 123:1351-1359
 All 3 anti-VEGF groups showed improvement of VA and decreased number of injections in year 2. Among eyes with worse baseline VA, aflibercept had superior 2 yr VA compared with bevacizumab, but superiority over ranibizumab in year 1 was no longer identified.

Effects of Medical Therapies on Retinopathy Progression in Type 2 DM

NEJM 2010;363:233-244
Purpose: To determine whether or not intensive glycemic control, combination therapy for dyslipidemia, and intensive blood-pressure control may limit the progression of DR in persons with type 2 DM.
Methods: RCT with 10,251 participants with type 2 DM at high risk of cardiovascular disease. Intensive or standard treatment for glycemia (glycated hemoglobin level <6.0% or 7.0-7.9%), dyslipidemia (160 mg daily fenofibrate plus simvastatin or placebo plus simvastatin), or systolic blood-pressure control (target <120 or <140 mm Hg).
Results: Rates of progression of DR at 4 yr were 7.3% with intensive glycemia treatment vs. 10.4% with standard therapy (OR 0.67; 95% CI 0.51-0.87); 6.5% with fenofibrate for intensive dyslipidemia therapy vs. 10.2% with placebo (OR 0.60; 95% CI 0.42-0.87) and 10.4% with intensive blood-pressure therapy vs. 8.8% with standard therapy (OR 1.23; 95% CI 0.84-1.79).
Conclusions: Intensive glycemic control and intensive combination treatment of dyslipidemia, but not intensive blood-pressure control, reduced the rate of DR.

Hypertension

- retinopathy is the most common ocular manifestation
- acute HTN retinopathy: retinal arteriolar spasm, superficial retinal hemorrhage, cotton wool spots, optic disc edema
- chronic HTN retinopathy: arteriovenous (AV) nicking, flame/blot retinal hemorrhages, microaneurysms, cotton wool spots
- increases risk of a number of other ocular diseases (DR, BRVO, CRAO/BRAO)

Table 10. Keith-Wagener-Barker Classification for Hypertensive Retinopathy

Group 1	Mild arterial narrowing
Group 2	Obvious arterial narrowing with focal irregularities
Group 3	Group 2 characteristics plus: Cotton wool spots Hemorrhage and/or exudate
Group 4	Group 3 plus papilledema

Multiple Sclerosis

- see [Neurology, N52](#)

Clinical Features

- blurred vision and decreased colour vision: secondary to optic neuritis
- central scotoma: due to damage to papillomacular bundle of retinal nerve fibres
- diplopia: secondary to INO
- RAPD, ptosis, nystagmus, uveitis, optic atrophy, optic neuritis
- white matter demyelinating lesions of optic nerve on MRI

Treatment

- IV steroids with taper to oral form for optic neuritis
 - DO NOT treat with oral steroids in isolation, as this increases likelihood of eventual development of MS

Corticosteroids for Treating Optic Neuritis

Cochrane Database Syst Rev 2015;8:CD001430
Summary: no conclusive evidence of benefit in terms of recovery to normal visual acuity, visual field, or contrast sensitivity six months after initiation of IV or oral corticosteroids.
Results: after review of 6 RCTs evaluating systemic corticosteroids for treatment of acute optic neuritis, all meta-analyses show similar outcomes for placebo vs. corticosteroid group for visual acuity, contrast sensitivity, and visual field.

TIA/Amaurosis Fugax

- sudden, transient blindness from intermittent vascular compromise
- ipsilateral carotid most frequent embolic source
- typically monocular, lasting <5-10 min
- Hollenhorst plaques (glistening microemboli seen at branch points of retinal arterioles)

Graves' Disease

- ophthalmopathy occurs despite control of thyroid gland status
- ocular manifestations occur secondary to sympathetic overdrive and/or specific inflammatory infiltrate of the orbital tissue

Clinical

- initial inflammatory phase is followed by a quiescent cicatricial phase

Treatment

- treat hyperthyroidism
- monitor for corneal exposure and maintain corneal hydration
- manage diplopia, proptosis, and compressive optic neuropathy with one or a combination of:
 - steroids (during acute phase)
 - orbital bony decompression
 - external beam radiation of the orbit
- consider strabismus and/or eyelid surgical procedures once acute phase subsides

Connective Tissue Disorders

- RA, juvenile idiopathic arthritis, SLE, Sjögren's syndrome, ankylosing spondylitis, polyarteritis nodosa
- most common ocular manifestation: dry eyes (keratoconjunctivitis sicca)

Giant Cell Arteritis/Temporal Arteritis

- see [Rheumatology, RH20](#)

Clinical Features

- more common in women >60 yr
- abrupt monocular loss of vision, pain over the temporal artery, jaw claudication, scalp tenderness, constitutional symptoms, and past medical history of polymyalgia rheumatica
- ischemic optic atrophy
- 50% lose vision in other eye if untreated

Diagnosis

- temporal artery biopsy + increased ESR (ESR can be normal, but likely 80-100 in first hour), increased CRP
- if biopsy of one side is negative, biopsy the other side

Treatment

- high dose corticosteroid to relieve pain and prevent further ischemic episodes
- if diagnosis of GCA is suspected clinically: start treatment + perform temporal artery biopsy to confirm diagnosis within 2 wk of initial presentation (DO NOT WAIT TO TREAT)

Sarcoidosis

- granulomatous uveitis with large "mutton fat" keratic precipitates and posterior synechiae
- complications include glaucoma, cataracts, retinal hemorrhages, peripheral retina neovascularization and dry eye
- neurosarcoidosis: optic neuropathy, oculomotor abnormalities, visual field loss

Treatment

- topical/systemic steroids and mydriatics

The most common cause of unilateral or bilateral proptosis in adults is Graves' disease

Progression of Signs and Symptoms of Graves' Ophthalmopathy

NO SPECS

No signs/symptoms

Only signs (lid retraction, lid lag)

Soft tissue swelling (periorbital edema)

Proptosis (exophthalmos)

Extraocular muscle weakness (causing diplopia)

Corneal exposure

Sight loss

ESR in Temporal Arteritis

Males > age/2

Females > (age + 10)/2

Does this Patient have Temporal Arteritis?

JAMA 2002;287:92-101

Rule in: jaw claudication and diplopia on history, temporal artery beading, prominence of the artery and tenderness over the artery on exam.

Rule out: no temporal artery abnormalities on exam, normal ESR.

Pediatric Ophthalmology

Strabismus

- ocular misalignment in one or both eyes, can be found in up to 3% of children
- classification
 - manifest (constant) vs. latent (hidden) alignment
 - comitant (deviation equal in all positions of gaze, also known as nonparalytic or concomitant) vs. incomitant (deviation worse in certain positions, also known as paralytic or restrictive)
 - described in direction of deviation relative to the fixating eye
- distinguish from pseudostrabismus (prominent epicanthal folds, hypertelorism)
- complications: amblyopia, cosmesis

Strabismus in children under 4 mo of age sometimes resolves, particularly if the deviation is intermittent, variable, or measures < 40 prism diopters

All children with strabismus and/or possible reduced vision require prompt referral to an ophthalmologist

HETEROTROPIA

- manifest deviation
- deviation not corrected by the fusion mechanism (i.e. deviation is apparent when the patient is using both eyes)

Types

- exo- (lateral deviation), eso- (medial deviation)
- hyper- (upward deviation), hypo- (downward deviation)
- esotropia = "crossed-eyes"; exotropia = "wall-eyed"

Tests

- Hirschberg test (corneal light reflex): positive if the light reflex on both corneas is asymmetrical
 - light reflex lateral to central cornea indicates esodeviation; light reflex medial to central cornea indicates exodeviation
 - false positives occur if visual axis and anatomic pupillary axis of the eye are not aligned (angle κ)
- cover test
- the deviation can be quantified using prisms

HETEROPHORIA

- latent deviation
- deviation corrected in the binocular state by the fusion mechanism (i.e. deviation not seen when patient is focusing with both eyes)
- Hirschberg test will be normal (light reflexes symmetrical)
- very common – majority are asymptomatic
- may be exacerbated or become manifest with asthenopia (eye strain, fatigue)

Tests

- cover-uncover test
- alternate cover test
 - alternating the cover between both eyes reveals the total deviation, both latent and manifest
 - maintain cover over one eye for 2-3 s before rapidly shifting to other eye

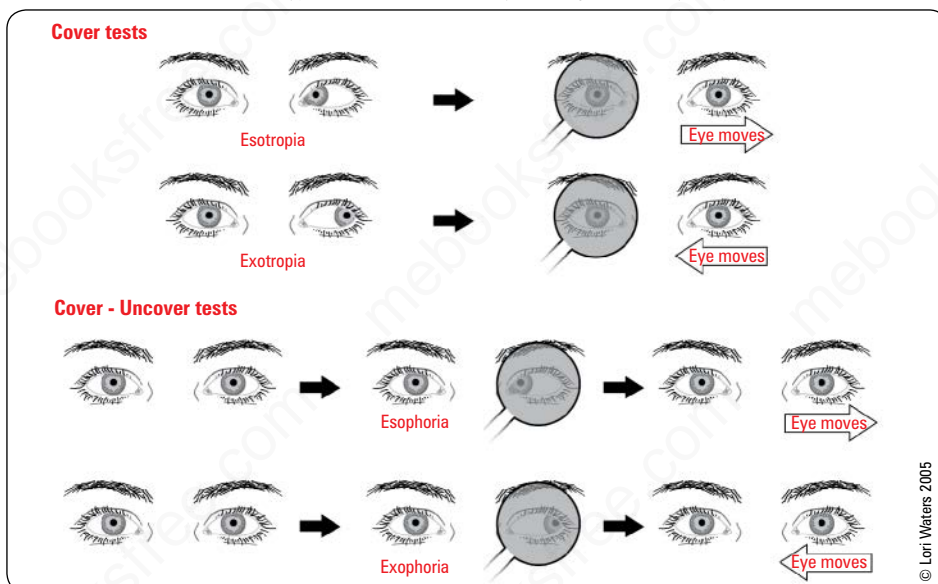

Figure 25. Cover and cover-uncover tests for detection of tropias and phorias

© Lori Waters 2005

Table 11. Paralytic vs. Non-Paralytic Strabismus

Clinical Characteristics	Paralytic Strabismus	Nonparalytic Strabismus
Definition	Incomitant strabismus	Concomitant strabismus
Onset	Often sudden but may be gradual or congenital	Usually gradual or shortly after birth; rarely sudden
Age of Onset	Any age; most often acquired	Usually during infancy
Etiology	Reduction or restriction in range of eye movements due to: Neural (CN III, IV, VI): ischemia (e.g. DM), MS, aneurysm, brain tumour, trauma Muscular: myasthenia gravis (neuromuscular junction pathology), Graves' disease Structural: restriction or entrapment of extraocular muscles due to orbital inflammation, tumour, fracture of the orbital wall	Develops early in childhood No restriction in range of eye movements Monocular, alternating, or intermittent
Diplopia	Common	Uncommon; image from the misaligned eye is suppressed
Visual Acuity in Other Eye	Usually unaffected in the other eye, unless CN II is involved	Deviated eye may become amblyopic if not treated when the child is young Amblyopia treatment rarely successful after age 8-10 yr Amblyopia usually does not develop if child has alternating strabismus or intermittency, which allows neural pathways for both eyes to develop
Possibility of Amblyopia	Uncommon	Common
Neurologic Findings or Systemic Disease	May be present	Usually absent

Accommodative Esotropia

- normal response to approaching object is the triad of the near reflex: convergence, accommodation, and miosis
- hyperopes must constantly accommodate – excessive accommodation can lead to esotropia in young children via over-activation of the near reflex
- average age of onset is 2.5 yr
- usually reversible with correction of refractive error

Non-Accommodative Esotropia

- accounts for 50% of childhood strabismus
- most are idiopathic
- may be due to monocular visual impairment (e.g. cataract, corneal scarring, anisometropia, retinoblastoma) or divergence insufficiency (ocular misalignment that is greater at distance fixation than at near fixation)

Amblyopia**Definition**

- a neurodevelopmental visual disorder with unilateral (or less commonly, bilateral) reduction of best corrected visual acuity that cannot be attributed only and directly to the effect of a structural abnormality of the eye
- it is caused by abnormal visual experience early in life and cannot be remedied immediately by spectacle glasses alone
- in approximately half of the cases, amblyopia is secondary to strabismus (mainly esotropia). Other causes may include uncorrected refractive errors, anisometropia (asymmetric refractive errors), and concomitant structural ocular problems

Detection

- “Holler Test”: young child upset if good eye is covered
- quantitative visual acuity by age 3-4 yr using picture charts and/or matching game (Sheridan-Gardiner), testing each eye separately
- amblyopia treatment less successful after age 8-10 yr, but a trial should be given no matter what age
- prognosis: 90% will have good vision restored and maintained if treated <4 yr old

Etiology and Management

- strabismus
 - correct with glasses for accommodative esotropia
 - occlusion therapy (see below)
 - surgery: recession (weakening) – moving muscle insertion further back on the globe; or resection (strengthening) – shortening the muscle
 - botulinum toxin for single muscle weakening
 - after ocular alignment is restored (glasses, surgery, botulinum toxin), patching is frequently necessary to maintain vision until ~8 yr of age
 - there is no proven value for vision training in the treatment of strabismus or amblyopia
- anisometropia
 - amblyopia usually in the more hyperopic eye
 - the more emmetropic (normal refraction) eye receives a clear image, while the less emmetropic eye receives a blurred image; input from the blurred eye is cortically suppressed and visual pathway fails to develop normally
 - treat with glasses to correct refractive error
 - patching is required if visual acuity difference persists after 4-8 wk of using glasses
- deprivation amblyopia
 - occlusion due to ptosis, cataract, retinoblastoma, corneal opacity
 - occlusion amblyopia: prolonged patching of good eye may cause it to become amblyopic

Occlusion Therapy

- patching the good eye to force the brain to use the non-dominant eye and redevelop its vision
- atropine cycloplegic drops to impair accommodation and blur vision of the better seeing eye

Risks

- permanent loss of vision in the affected eye
- possibility of injury to “remaining” good eye
- safety glasses or polycarbonate lenses recommended if visual acuity in worse eye is <20/50
- loss of stereopsis

Leukocoria

- white reflex (red reflex is absent)
- the presence of leukocoria warrants urgent referral to an ophthalmologist

Differential Diagnosis

- cataract
- retinoblastoma
- retinal coloboma
- ROP
- persistent hyperplastic primary vitreous or persistent fetal vasculature
- Coat's disease (exudative retinal telangiectasis)
- toxocariasis
- RD

Retinoblastoma

- most common primary intraocular malignancy in children
- incidence: 1/15,000; sporadic or genetic transmission; screening of siblings/offspring essential
- unilateral (2/3) or bilateral (1/3)
- malignant – direct or hematogenous spread
- diagnosis
 - often presents with leukocoria or strabismus
 - U/S or CT scan may demonstrate calcified mass (present in most cases)

Treatment

- radiotherapy, chemotherapy combined with laser, cryopexy, and/or enucleation

Retinopathy of Prematurity

- vasoproliferative retinopathy that is a major cause of blindness in the developed world

Risk Factors

- non-black race (black infants have lower risk of developing ROP)
- low gestational age, birth weight <1500 g
- high oxygen exposure after birth (iatrogenic)

Retinal Zones

- Zone I: circle with radius twice the distance from the disc to the macula (most difficult to treat)
- Zone II: annulus from zone I to nasal extent of retina (nasal ora serrata)
- Zone III: remaining retina

Figure 26. Zones of the retina in ROP

Classification (ROP Staging)

- stage 1: faint demarcation line at the junction between the vascularized and avascular retina
- stage 2: elevated ridge
- stage 3: extra-retinal fibrovascular tissue extending into vitreous
- stage 4: partial RD (4A: macula "on", 4B: macula "off")
- stage 5: total RD
- plus (+) disease: dilatation and tortuosity of retinal vessels
- threshold disease: stage 3+ in zones 1 or 2 with circumferential extent of disease of 5 continuous or 8 cumulative clock hours (1-12) of ROP involvement

Treatment

- threshold disease is treated with cryotherapy or laser (laser is now the standard treatment, with better refractive outcome); more recently, off-label anti-VEGF intravitreal injections
- ROP beyond threshold level is either watched carefully (usually stage 4A) or treated with vitrectomy/scleral buckle

Prognosis

- higher incidence of myopia among ROP infants, even if treated successfully
- stage 4B and 5 have poor prognosis for visual outcome despite treatment

VEGF in Treatment of Retinopathy of Prematurity (ROP)

Cochrane Database Syst Rev 2016;2:CD009734.

Summary/Results: Review of 3 RCTs/Quasi-RCTs comparing anti-VEGF agents vs. conventional therapy for ROP (n=239). Insufficient data precludes strong conclusions for routine use of intravitreal anti-VEGF agents for treatment of ROP

- Intravitreal bevacizumab monotherapy reduces risk of refractory errors during childhood.
- Intravitreal pegatanib + laser therapy reduces the risk of retinal detachment for type 1 ROP.
- Effect on other critical outcomes and long-term systemic adverse effects are unknown.

Nasolacrimal System Defects

- congenital obstruction of the nasolacrimal duct (failure of canalization), usually occurs at 1-2 mo of age
- epiphora, crusting, discharge, recurrent conjunctivitis
- can have reflux of mucopurulent material from lacrimal punctum when pressure is applied over lacrimal sac

Treatment

- massage over lacrimal sac at medial corner of eyelid
- vast majority spontaneously resolve in 9-12 mo, otherwise consider referral for duct probing

Ophthalmia Neonatorum

- newborn conjunctivitis in first month of life
- causes
 - chemical/toxic: silver nitrate, erythromycin (secondary to prophylaxis, self-limiting)
 - infectious: bacterial (e.g. *N. gonorrhoeae* – most common, *C. trachomatis*), herpes simplex virus
- diagnose using stains and cultures

Treatment

- systemic antibiotics with possible hospitalization if infectious etiology
- topical prophylaxis, most commonly with erythromycin (or silver nitrate), is required by law at birth

Gonococcal infection is the most serious threat to sight as it can rapidly penetrate corneal epithelium, causing corneal ulceration

Congenital Glaucoma

- due to inadequate development of the filtering mechanism of the anterior chamber angle

Clinical Features

- cloudy cornea, increased IOP
- photophobia, epiphora
- buphthalmos (large cornea, "ox eye", secondary to increased IOP), blepharospasm

Treatment

- filtration surgery is required soon after birth to prevent blindness

Epiphora in children – rule out congenital glaucoma

Ocular Trauma

Blunt Trauma

- caused by blunt object such as fist
- history: injury, ocular history, drug allergy, tetanus status
- exam: VA first, pupil size and reaction, EOM (diplopia), external and slit-lamp exam, ophthalmoscopy
- if VA normal or slightly reduced, globe less likely to be perforated
- if VA reduced: may be perforated globe, corneal abrasion, lens dislocation, retinal tear
- bone fractures
 - blow out fracture: restricted EOM, diplopia, enophthalmos (sunken eye)
 - ethmoid fracture: subcutaneous emphysema of lid
- lids: swelling, laceration, emphysema

Always test VA first – medicolegal protection

Refer if You Observe Any of These Signs

- Decreased VA
- Shallow anterior chamber
- Hyphema
- Abnormal pupil
- Ocular misalignment
- Retinal damage

- conjunctiva: subconjunctival hemorrhage
- cornea: abrasion – detect with fluorescein staining and cobalt blue filter using slit-lamp or ophthalmoscope
- anterior chamber: assess depth, hyphema, hypopyon
- iris: prolapse, iritis
- lens: cataract, dislocation
- retinal tear/detachment

Penetrating Trauma

- include ruptured globe ± prolapsed iris, intraocular foreign body
- rule out intraocular foreign body, especially if history of “metal striking metal”, CT orbit
- **OCULAR EMERGENCY**: initial management - REFER IMMEDIATELY
 - ABCs
 - don't press on eye globe!
 - don't check IOP if possibility of globe rupture
 - check vision, diplopia
 - apply rigid eye shield to minimize further trauma
 - keep head elevated 30-45° to keep IOP down
 - keep NPO
 - tetanus status
 - give IV antibiotics
 - ♦ selecting appropriate agents depends on the mechanism of injury; Gram-positive bacteria are more commonly involved than Gram-negative; retained intraocular foreign objects increase the risk of infections with Bacillus species, whereas exposure to vegetable matter increase the risk of a fungal etiology

Management of Suspected Globe Rupture
CAN'T forget
CT orbits
Ancef (cefazolin) ± Aminoglycoside IV
NPO
Tetanus status

Post-Traumatic Infectious Endophthalmitis
Surv Ophthalmol 2011;56:214-251

- Delayed primary repair (>24 h after open globe injury) increases risk for post-traumatic endophthalmitis in the absence of an intraocular foreign body (IOFB).
- If IOFB present, early vitrectomy and IOFB removal must be performed within 24 h of injury.
- Extreme pain with hypopyon and vitritis indicate endophthalmitis until proven otherwise, and samples must be obtained.
- Treat with empirical intravitreal and intravenous antibiotic guided by nature of trauma, and adjust based on culture.

Shaken Baby Syndrome
 Syndrome of findings characterized by absence of external signs of abuse with respiratory arrest, seizures, or coma. Ocular exam findings are important diagnostically for Shaken Baby Syndrome. These findings include extensive retinal and vitreous hemorrhages that occur during the shaking process and are extremely rare in accidental trauma. A detailed fundoscopic exam or an ophthalmology referral should be conducted for all infants in whom abuse is suspected

Hyphema

- blood in anterior chamber, often due to damage to root of the iris
- may occur with blunt trauma

Treatment

- refer to ophthalmology
- shield and bedrest x 5 d or as determined by ophthalmologist
- sleep with head upright
- may need surgical drainage if hyphema persists or if re-bleed

Complications

- risk of re-bleed highest on d 2-5, resulting in secondary glaucoma, corneal staining, and iris necrosis
- never prescribe Aspirin®, as it increases the risk of a re-bleed

Blow-Out Fracture

- see [Plastic Surgery, PL33](#)
- blunt trauma causing fracture of orbital floor and herniation of orbital contents into maxillary sinus
- orbital rim remains intact
- inferior rectus and/or inferior oblique muscles may be incarcerated at fracture site
- infraorbital nerve courses along the floor of the orbit and may be damaged

Clinical Features

- pain and nausea at time of injury
- diplopia, restriction of EOM
- infraorbital and upper lip paresthesia (CN V2)
- enophthalmos (sunken eye), periorbital ecchymoses

Investigations

- plain films: Waters' view and lateral
- CT: anteroposterior and coronal view of orbits

Treatment

- refrain from coughing, blowing nose
- systemic antibiotics may be indicated
- surgery if fracture >50% orbital floor, diplopia not improving, or enophthalmos >2 mm
- may delay surgery if the diplopia improves

Classic Signs of Blow-Out

- Enophthalmos
- Decreased upgaze (IR trapped)
- Cheek anesthetized (infraorbital nerve trapped)

Chemical Burns

- alkali burns have a worse prognosis than acid burns because acids coagulate tissue and inhibit further corneal penetration
- poor prognosis if cornea opaque, likely irreversible stromal damage
- even with a clear cornea initially, alkali burns can progress for weeks (thus, very guarded prognosis)

Treatment

- immediately irrigate at site of accident with water or buffered solution
 - irrigate with eyelids retracted in emergency department with IV drip until pH physiologic
 - swab upper and lower fornices to remove possible particulate matter
- do not attempt to neutralize an acid with a base, or vice versa
- cycloplegic drops to decrease iris spasm (pain) and prevent secondary glaucoma (due to posterior synechiae formation)
- topical antibiotics and patching
- topical steroids (by ophthalmologist) to decrease inflammation, use for <2 wk (in the case of a persistent epithelial defect)

Ocular Drug Toxicity

Table 12. Drugs with Ocular Toxicity

Amiodarone	Corneal microdeposits and superficial keratopathy (vortex keratopathy) Rare: ischemic optic neuropathy
Atropine, benzotropine	Pupillary dilation (risk of angle closure glaucoma)
Bisphosphonates (Fosamax®, Actonel®)	Inflammatory eye disease (iritis, scleritis, episcleritis)
Chloroquine, hydroxychloroquine	Bull's eye maculopathy Vortex keratopathy
Chlorpromazine	Anterior subcapsular cataract
Contraceptive pills	Decreased tolerance to contact lenses Migraine Optic neuritis Central vein occlusion, benign increase intracranial pressure
Digitalis	Yellow vision Blurred vision
Ethambutol	Optic neuropathy
Haloperidol (Haldol®)	Oculogyric crises Blurred vision
Indomethacin	Superficial keratopathy
Interferon	Retinal hemorrhages and cotton wool spots
Isoniazid	Optic neuropathy
Nalidixic acid	Papilledema
Steroids	Posterior subcapsular cataracts Glaucoma Papilledema (systemic steroids) Increased severity of HSV infections (geographic ulcers) Predisposition to fungal infections
Sulphonamides, NSAIDs	Stevens-Johnson syndrome
Tamsulosin (Flomax®)	Intraoperative Floppy Iris Syndrome, which can complicate cataract surgery
Tetracycline	Papilledema (associated with pseudotumour cerebri)
Thioridazine	Pigmentary degeneration of retina
Vigabatrin	Retinal deposition with macular sparing, peripheral visual field loss
Vitamin A toxicity	Papilledema
Vitamin D toxicity	Band keratopathy

Common Medications

TOPICAL OCULAR DIAGNOSTIC DRUGS

Fluorescein Dye

- water soluble orange-yellow dye
- green under cobalt blue light (ophthalmoscope or slit-lamp)
- absorbed in areas of epithelial loss (ulcer or abrasion)
- also stains mucus and contact lenses

Rose Bengal Stain

- stains devitalized epithelial cells and mucus

Anesthetics

- e.g. proparacaine HCl 0.5%, tetracaine 0.5%
- indications: removal of foreign body and sutures, tonometry, examination of painful cornea
- toxic to corneal epithelium (inhibit mitosis and migration) and can lead to corneal ulceration and scarring with prolonged use, therefore **NEVER** prescribe

Mydriatics

- dilate pupils
- two classes
 - cholinergic blocking (e.g. tropicamide – Mydracyl®)
 - ♦ dilation plus cycloplegia (loss of accommodation) by paralysis of iris sphincter and the ciliary body
 - ♦ indications: refraction, ophthalmoscopy, therapy for iritis
 - adrenergic stimulating (e.g. phenylephrine HCl 2.5%)
 - ♦ stimulate pupillary dilator muscles, no effect on accommodation
 - ♦ usually used with tropicamide for additive effects
 - ♦ side effects: HTN, tachycardia, arrhythmias

Table 13. Mydriatic Cycloplegic Drugs and Duration of Action

Drugs	Duration of Action
Tropicamide (Mydracyl®) 0.5%, 1%	4-5 h
Cyclopentolate HCl 0.5%, 1%	3-6 h
Homatropine HBr 1%, 2%	3-7 d
Atropine sulfate 0.5%, 1%	1-2 wk
Scopolamine HBr 0.25%, 5%	1-2 wk

Green	Cholinergics
Red	Anti-Cholinergics
White	Anaesthetics, Antibiotics, Artificial tears, Steroids
Yellow	Beta-Blockers
Blue	Beta-Blocker combinations
Purple	Alpha-Agonists
Teal	Prostaglandins
Orange	Carbonic Anhydrase Inhibitors
Tan	Fluoroquinolones
Grey	NSAIDs
Pink	Anti-inflammatories, Steroids

GLAUCOMA MEDICATIONS

Table 14. Glaucoma Medications

Drug Category	Dose	Effect	Comment/Side Effects
α-Agonist Non-selective <ul style="list-style-type: none"> • epinephrine HCl 1% (Epirin®) • dipivalyl epinephrine 0.1% (Propine®) α2-selective <ul style="list-style-type: none"> • brimonidine 0.2% (Alphagan®) • apraclonidine 0.5% (Iopidine®) 	1 gtt OS/OD bid/tid	1. Non-selective: ↓ aqueous production + ↑ TM outflow 2. Selective: ↓ aqueous production + ↑ uveoscleral outflow	1. Non-selective: mydriasis, macular edema, tachycardia 2. Selective: contact allergy, hypotension in children
β-Blocker Non-selective <ul style="list-style-type: none"> • timolol (Timoptic®) • levobunolol (Betagan®) β1-selective betaxolol (Betoptic®)	1 gtt OS/OD qd/bid	↓ aqueous production	Bronchospasm (caution in asthma/COPD) ↑ CHF Bradycardia, hypotension, depression, heart block, impotence
Carbonic Anhydrase Inhibitor <ul style="list-style-type: none"> • dorzolamide (Trusopt®) • brinzolamide (Azopt®) • oral: acetazolamide (Diamox®), methazolamide (Neptazane®) 	1 gtt OS/OD tid Diamox®: 500 mg PO bid	↓ aqueous production	Must ask about sulfa allergy Generally local side effects with topical preparations Oral: diuresis, fatigue, paresthesias, GI upset, etc.
Parasympathomimetic (cholinergic stimulating) <ul style="list-style-type: none"> • pilocarpine (Pilopine®) • carbachol (Isopto Carbachol®) 	1-2 gtts OS/OD tid/qid	↑ TM outflow	Miosis ↓ night vision ↑ GI motility, brow ache, headache ↓ heart rate
Prostaglandin Analogues <ul style="list-style-type: none"> • latanoprost (Xalatan®) • travaprost (Travatan®) • bimatoprost (Lumigan®) 	1 gtt OS/OD qhs	↑ uveoscleral outflow (uveoscleral responsible for 20% of drainage)	Iris colour change Periocular skin pigmentation Lash growth Conjunctival hyperemia

Cosopt® = timolol + dorzolamide; Xalatan® = timolol + lantanoprost; Combigan® = timolol + brimonidine; DuoTrav® = timolol + travaprost; gtt = drop, gtts = drops

WET AGE-RELATED MACULAR DEGENERATION MEDICATIONS

VEGF Inhibitors

- block VEGF which prevents ocular angiogenesis and further development of choroidal neovascularization
- administered via intravitreal injections
- pegaptanib (Macugen[®]) is a selective anti-VEGF targeting VEGF isoform 165 (no longer widely used)
- ranibizumab (Lucentis[®]) is a non-selective anti-VEGF agent
- aflibercept (Eylea[®]) is an VEGF “trap” agent that binds VEGF-A and placental growth factor
- bevacizumab (Avastin[®]) is another non-selective anti-VEGF agent, but is only FDA approved for metastatic breast cancer, colorectal cancer, and non-small cell lung cancer; therefore, its widespread ophthalmologic use is off-label

TOPICAL OCULAR THERAPEUTIC DRUGS

NSAIDs

- used for less serious chronic inflammatory conditions
- e.g. ketorolac (Acular[®]), diclofenac (Voltaren[®]), nepafenac (Nevanac[®]) drops

Anti-Histamines

- used to relieve red and itchy eye, often in combination with decongestants
- sodium cromoglycate – stabilizes membranes

Decongestants

- weak adrenergic stimulating drugs (vasoconstrictor)
- e.g. naphazoline, phenylephrine (Isopto Frin[®])
- rebound vasodilation with overuse; rarely can precipitate angle closure glaucoma

Antibiotics

- indications: bacterial conjunctivitis, keratitis, or blepharitis
- commonly as topical drops or ointments, may give systemically
- e.g. sulfonamide (sodium sulfacetamide, sulfisoxazole), gentamicin (Garamycin[®]), erythromycin, tetracycline, bacitracin, polymyxin B, fluoroquinolones (ciprofloxacin [Ciloxan[®]], ofloxacin [Ocuflox[®]], moxifloxacin [Vigamox[®]], gatifloxacin [Zymar[®]])

Corticosteroids

- e.g. fluorometholone (FML[®]), betamethasone, dexamethasone (Maxidex[®]), prednisolone (Predsol[®] 0.5%, Pred Forte[®] 1%), rimexolone (Vexol[®]), loteprednol etabonate 0.5% (Lotamax[®]), difluprednate (Durezol[®])
- primary care physicians should avoid prescribing topical corticosteroids due to risk of glaucoma, cataracts, and reactivation of HSV keratitis
- complications
 - potentiates HSV keratitis and fungal keratitis as well as masking symptoms
 - increased IOP, more rapidly in steroid responders (within weeks)
 - posterior subcapsular cataract (within months)

Figure 3. Nerves and arteries of lower limbs

Fractures – General Principles

Fracture Description

1. Name of Injured Bone

2. Integrity of Skin/Soft Tissue

- closed: skin/soft tissue over and near fracture is intact
- open: skin/soft tissue over and near fracture is lacerated or abraded, fracture exposed to outside environment, or contaminated (i.e. bowel)
- signs: continuous bleeding from puncture site or fat droplets in blood are suggestive of an open fracture

3. Location (Figure 5)

- epiphyseal: end of bone, forming part of the adjacent joint
- metaphyseal: the flared portion of the bone at the ends of the shaft
- diaphyseal: the shaft of a long bone (proximal, middle, distal)
- physis: growth plate

4. Orientation/Fracture Pattern (Figure 4)

- transverse: fracture line perpendicular (<30° of angulation) to long axis of bone; result of direct high energy force
- oblique: angular fracture line (30° - 60° of angulation); result of angulation and compressive force, high energy
- butterfly: fracture site fragment which looks like a butterfly
- segmental: a separate segment of bone bordered by fracture lines; result of high energy force
- spiral: complex, multi-planar fracture line; result of rotational force, low energy
- comminuted/multi-fragmentary: >2 fracture fragments
- intra-articular: fracture line crosses articular cartilage and enters joint
- avulsion: tendon or ligament tears/pulls off bone fragment; often in children, high energy
- compression/impacted: impaction of bone; typical sites are vertebrae or proximal tibia
- torus: a buckle fracture of one cortex, often in children (Figure 49)
- greenstick: an incomplete fracture of one cortex, often in children (Figure 49)
- pathologic: fracture through bone weakened by disease/tumour

5. Alignment of Fracture Fragments

- non-displaced: fracture fragments are in anatomic alignment
- displaced: fracture fragments are not in anatomic alignment
- distracted: fracture fragments are separated by a gap (opposite of impacted)
- impacted: fracture fragments are compressed, resulting in shortened bone
- angulated: direction of fracture apex (e.g. varus/valgus)
- translated/shifted: percentage of overlapping bone at fracture site
- rotated: fracture fragment rotated about long axis of bone

Figure 4. Fracture types

Displacement
Refers to position of the distal fragment relative to the proximal fragment

Varus/Valgus Angulation
Varus = Apex away from midline
Valgus = Apex toward midline

Figure 5. Schematic diagram of the long bone

Quick Motor Nerve Exam
"Thumbs Up": PIN (Radial Nerve)
"OK Sign": AIN (Median Nerve)
"Spread Fingers": Ulnar Nerve

X-Ray Rule of 2s
2 sides = bilateral
2 views = AP + lateral
2 joints = joint above + below
2 times = before + after reduction

Reasons for Splinting

- Pain control
- Reduces further damage to vessels, nerves, and skin and may improve vascular status
- Decreases risk of inadvertently converting closed to open fracture
- Facilitates patient transport

Indications for Open Reduction

NO CAST
Non-union
Open fracture
Neurovascular Compromise
Displaced intra-Articular fracture
Salter-Harris 3,4,5
PolyTrauma

Buck's Traction
A system of weights, pulleys, and ropes that are attached to the end of a patient's bed exerting a longitudinal force on the distal end of a fracture, improving its length, alignment, and rotation

Approach to Fractures

1. Clinical Assessment

- ABCs, primary survey, and secondary survey (ATLS protocol)
 - rule out other fractures/injuries
 - rule out open fracture
- AMPLE history (minimum): Allergies, Medications, Past medical history, Last meal, Events surrounding injury
 - mechanism of injury
 - previous significant injury or surgery to affected area
 - consider pathologic fracture with history of only minor trauma
- Physical exam: look (deformity, soft tissue integrity); feel (maximal tenderness, NVS-document best possible neurovascular exam, avoid ROM/moving injured area to prevent exacerbation)

2. Analgesia

3. Imaging (see Orthopedic X-Ray Imaging, OR7)

4. Splint Extremity

5. Management: Closed vs. Open Reduction

1. obtain the reduction (see appropriate IV sedation, see Table 27, OR48)
 - closed reduction
 - apply traction in the long axis of the limb
 - reverse the mechanism that produced the fracture
 - reduce with IV sedation and muscle relaxation (fluoroscopy can be used if available)
 - indications for open reduction
 - "NO CAST"
 - other indications include
 - failed closed reduction
 - not able to cast or apply traction due to site (e.g. hip fracture)
 - pathologic fractures
 - potential for improved function with ORIF
- ALWAYS re-check and document NVS after reduction and obtain post-reduction x-ray

2. maintain the reduction
 - external stabilization: splints, casts, traction, external fixator
 - internal stabilization: percutaneous pinning, extramedullary fixation (screws, plates, wires), IM fixation (rods)
 - follow-up: evaluate bone healing
3. rehabilitate to regain function and avoid joint stiffness

Fracture Healing

Normal Healing

Weeks 0-3	Hematoma, macrophages surround fracture site
Weeks 3-6	Osteoclasts remove sharp edges, callus forms within hematoma
Weeks 6-12	Bone forms within the callus, bridging fragments
Months 6-12	Cortical gap is bridged by bone
Years 1-2	Normal architecture is achieved through remodelling

Figure 6. Stages of bone healing

Evaluation of Healing: Tests of Union

- clinical: no longer tender to palpation or stressing on physical exam
- x-ray: trabeculae cross fracture site, visible callus bridging site on at least 3 of 4 cortices

General Fracture Complications

Table 2. General Fracture Complications

	Early	Late
Local	Compartment syndrome Neurological injury Vascular injury Infection Implant failure Fracture blisters	Mal-/non-union AVN Osteomyelitis Heterotopic ossification Post-traumatic OA Joint stiffness/adhesive capsulitis CRPS type I/RSD
Systemic	Sepsis DVT PE ARDS secondary to fat embolism Hemorrhagic shock	

Heterotopic Ossification

The formation of bone in abnormal locations (e.g. in muscle), secondary to pathology

Wolff's Law

Bone remodels itself to over time in response to mechanical load to better withstand loading stressors placed upon it

Avascular Necrosis

Ischemia of bone due to disrupted blood supply; most commonly affecting the femoral neck, talus neck, or proximal scaphoid

Fracture Blister

Formation of vesicles or bullae that occur on edematous skin overlying a fractured bone

Osteochondritis dissecans

Osteonecrosis of subchondral bone most often occurring in children and adolescents and causing pain and potentially hindering joint motion

Articular Cartilage

Properties

- 2-4 mm layer covering ends of articulating bones, provides nearly frictionless surface
- avascular (nutrition from synovial fluid), aneural, alymphatic

ARTICULAR CARTILAGE DEFECTS

Etiology

- overt trauma, repetitive minor trauma (such as repetitive ankle sprains or patellar maltracking); common sports injury
- degenerative conditions such as early stage OA or osteochondritis dissecans

Clinical Features

- similar to symptoms of OA (joint line pain with possible effusion, etc.)
- often have predisposing factors, such as ligament injury, malalignment of the joint (varus/valgus), obesity, bone deficiency (AVN, osteochondritis dissecans, ganglion bone cysts), inflammatory arthropathy, and familial osteoarthritis
- may have symptoms of locking or catching related to the torn/displaced cartilage

Investigations

- x-ray (to rule out bony defects and check alignment)
- MRI
- diagnostic arthroscopy (treatment is often guided by what is seen during arthroscopy)

Table 3. Outerbridge Classification of Chondral Defects

Grade	Chondral Damage
I	Softening and swelling of cartilage
II	Fragmentation and fissuring <1/2" in diameter
III	Fragmentation and fissuring >1/2" in diameter
IV	Erosion of cartilage down to bone

Treatment

- individualized
 - patient factors (age, skeletal maturity, activity level, etc.)
 - defect factors (Outerbridge Classification, subchondral bone involvement, etc.)
- non-operative
 - rest, NSAIDs, bracing
- operative
 - microfracture, osteochondral grafting (autograft or allograft), autologous chondrocyte implantation

Orthopedic X-Ray Imaging

General Principles

- x-ray 1 joint above and 1 below
- obtain at least 2 orthogonal views ± specialized views

Table 4. Orthopedic X-Ray Imaging

Site	Injury	X-Ray Views	
Shoulder	Anterior dislocation	AP	
	Posterior dislocation	Axillary ± stress view with 10 lb in hand	
	AC	Trans-scapular	
	Frozen shoulder	Zanca view (10-15 cephalic tilt)	
Arm	Humerus #	AP Lateral Trans-scapular Axillary	
	Elbow/Forearm	Supracondylar #	AP
		Radial head #	Lateral
		Monteggia #	
		Night stick #	
Galeazzi #			
Wrist	Colles' #	AP	
	Smith #	Lateral	
	Scaphoid #	Scaphoid (wrist extension and ulnar deviation x 2 wk)	
Pelvis	Pelvic #	AP pelvis Inlet and outlet views Judet views (obturator and iliac oblique for acetabular #)	
Hip	Femoral head/neck #	AP	
	Intertrochanteric #	Lateral	
	Arthritis	Frog-leg lateral	
	SCFE	Dunn	
	FAI		
Knee	Knee dislocation	AP standing, lateral	
	Femur/tibia #	Skyline – tangential view with knees flexed at 45° to see patellofemoral joint	
	Patella #		
	Patella dislocation		
	Patella femoral syndrome Tibia shaft #		
Ankle	Ankle #	AP Lateral Mortise view: ankle at 15° of internal rotation	
Foot	Talar #	AP	
	Calcaneal #	Lateral Harris Axial	
Spine	Compression #	AP spine	
	Burst #	AP odontoid	
	Cervical spine #	Lateral	
		Oblique	
		Swimmer's view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate Lateral flexion/extension view: evaluate subluxation of cervical vertebrae	

CRPS/RSD

An exaggerated response to an insult in the extremities; characterized by symptoms of hyperalgesia and allodynia, with signs of autonomic dysfunction (temperature asymmetry, mottling, hair or nail changes)

Orthopedic Emergencies

Trauma Patient Workup

Etiology

- high energy trauma e.g. MVC, fall from height
- may be associated with spinal injuries or life-threatening visceral injuries

Clinical Features

- local swelling, tenderness, deformity of the limbs, and instability of the pelvis or spine
- decreased level of consciousness, hypotension/hypovolemia
- consider involvement of EtOH or other substances

Investigations

- trauma survey (see [Emergency Medicine, ER7, ER15](#))
- x-rays: lateral cervical spine, AP chest, AP pelvis, AP and lateral of all bones suspected to be injured
- CT is also utilized to inspect for musculoskeletal injuries in the trauma setting
- other views of pelvis: AP, inlet, and outlet; Judet views for acetabular fracture (for [Classification of Pelvic Fractures see Table 18, OR27](#))

Treatment

- ABCDEs and initiate resuscitation for life-threatening injuries
- assess genitourinary injury (rectal exam/vaginal exam mandatory)
- external or internal fixation of all fractures
- DVT prophylaxis

Complications

- hemorrhage – life-threatening (may produce signs and symptoms of hypovolemic shock)
- fat embolism syndrome (SOB, hypoxemia, petechial rash, thrombocytopenia, and neurological symptoms)
- venous thrombosis – DVT and PE
- bladder/urethral/bowel injury
- neurological damage
- persistent pain/stiffness/limp/weakness in affected extremities
- post-traumatic OA of joints with intra-articular fractures
- sepsis if missed open fracture

Open Fractures

- fractured bone and hematoma in communication with the external or contaminated environment

Emergency Measures

- ABCs, primary survey, and resuscitation as needed
- removal of obvious foreign material
- irrigate with normal saline if grossly contaminated
- cover wound with sterile dressings
- immediate IV antibiotics
- tetanus toxoid or immunoglobulin as needed
- reduce and splint fracture
- NPO and prepare for OR (blood work, consent, ECG, CXR)
 - operative irrigation and debridement within 6-8 h to decrease risk of infection
 - traumatic wound often left open to drain but vacuum-assisted closure dressing may be used
 - re-examine with repeat irrigation and debridement in 48 h

Table 5. Gustilo Classification of Open Fractures

Gustilo Grade	Length of Open Wound	Description	Prophylactic Antibiotic Regimen
I	<1 cm	Minimal contamination and soft tissue injury Simple or minimally comminuted fracture	First generation cephalosporin (cefazolin) for 3 d If allergy use fluoroquinolone If MRSA positive use vancomycin
II	1-10 cm	Moderate contamination Moderate soft tissue injury	As per Grade I
III*	>10 cm	IIIA: Extensive soft tissue injury with adequate ability of soft tissue to cover wound IIIB: Extensive soft tissue injury with periosteal stripping and bone exposure; inadequate soft tissue to cover wound IIIC: Vascular injury/compromise	First generation cephalosporin (cefazolin) for 3 d plus Gram-negative coverage (gentamicin) for at least 3 d For soil contamination, penicillin is added for clostridial coverage

*Any high energy, comminuted fracture, shot gun, farmyard/soil/water contamination, exposure to oral flora, or fracture >8 h old is immediately classified as Grade III

Orthopedic Emergencies

VON CHOP

- Vascular compromise
- Open fracture
- Neurological compromise/cauda equina syndrome
- Compartment syndrome
- Hip dislocation
- Osteomyelitis/septic arthritis
- Unstable Pelvic fracture

Controversies in Initial Management of Open Fractures

Scand J Surg 2014;103(2):132-137

Study: Literature review examining the initial management of open fractures. 40 studies included.

Findings:

- A first-generation cephalosporin (or clindamycin) should be administered upon arrival. In general, 24 h of antibiotics after each debridement is sufficient to reduce infection rates.
- Although cultures are taken from delayed (>24 h) or infected injuries, it may not be necessary to routinely take post-debridement cultures in open fractures.
- Open fractures should be debrided as soon as possible, although the "6-h rule" is not generally valid.
- Wounds should be closed within 7 d once soft tissue has stabilized and all non-viable tissue removed.
- Negative pressure wound therapy (NPWT) has been shown to decrease infection rates in open fractures.

33% of patients with open fractures have multiple injuries

Antibiotics for Preventing Infection in Open Limb Fractures

Cochrane DB Syst Rev 2004;1:CD003764

Purpose: To review the evidence regarding the effectiveness of antibiotics in the initial treatment of open fractures of the limbs.

Methods: Randomized or quasi-randomized controlled trials comparing antibiotic treatment with placebo or no treatment in preventing acute wound infection were identified and reviewed. Data were extracted and pooled for analysis.

Results: Eight studies (n=1,106) were reviewed. The use of antibiotics had a protective effect against early infection compared with no antibiotics or placebo (RRR=0.43, 95% CI 0.29, 0.65; ARR=0.07, 95% CI 0.03=0.10).

Conclusions: Antibiotics reduce the incidence of early infections in open fractures of the limbs.

Cauda Equina Syndrome

- see [Neurosurgery, NS27](#)

Cauda equina syndrome is a surgical emergency

Compartment Syndrome

- increased interstitial pressure in an anatomical compartment (forearm, calf) where muscle and tissue are bounded by fascia and bone (fibro-osseous compartment), with little room for expansion
- interstitial pressure exceeds capillary perfusion pressure, leading to muscle necrosis (in 4-6 h) and eventually nerve necrosis

Etiology

- intracompartmental
 - fracture (particularly tibial shaft or paediatric supracondylar and forearm fractures)
 - reperfusion injury, crush injury, or ischemia
- extracompartmental: constrictive dressing (circumferential cast), poor position during surgery, circumferential burn

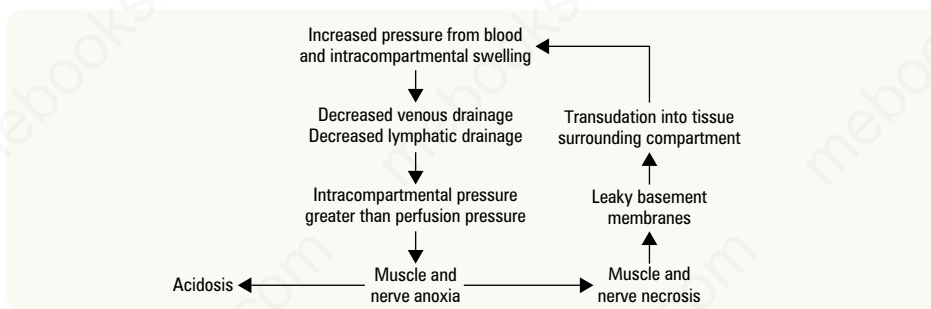

Figure 7. Pathogenesis of compartment syndrome

Clinical Features

- pain out of proportion to injury (typically first symptom)
- pain with active contraction of compartment
- pain with passive stretch (most sensitive)
- swollen, tense compartment
- suspicious history
- **5 Ps:** late sign – do not wait for these to develop to make the diagnosis!

Investigations

- usually not necessary, as compartment syndrome is a clinical diagnosis
- in children or unconscious patients where clinical exam is unreliable, compartment pressure monitoring with catheter AFTER clinical diagnosis is made (normal = 0 mmHg; elevated ≥ 30 mmHg or [measured pressure – dBP] ≤ 30 mmHg)

Treatment

- non-operative
 - remove constrictive dressings (casts, splints), elevate limb at the level of the heart
- operative
 - urgent fasciotomy
 - 48-72 h post-operative: wound closure \pm necrotic tissue debridement

Complications

- Volkmann's ischemic contracture: ischemic necrosis of muscle, followed by secondary fibrosis, and finally calcification; especially following supracondylar fracture of humerus
- rhabdomyolysis, renal failure secondary to myoglobinuria

Osteomyelitis

- bone infection with progressive inflammatory destruction

Etiology

- most commonly caused by *S. aureus*
- mechanism of spread: hematogenous (most common) vs. direct-inoculation vs. contiguous focus
- risk factors: recent trauma/surgery, immunocompromised patients, DM, IV drug use, poor vascular supply, peripheral neuropathy

Most important sign is increased pain with passive stretch. Most important symptom is pain out of proportion to injury

5 Ps of Compartment Syndrome

- Pain:** out of proportion for injury and not relieved by analgesics
- Increased pain with passive stretch of compartment muscles
- Pallor:** late finding
- Paresthesia**
- Paralysis:** late finding
- Pulselessness:** late finding

Plain Film Findings of Osteomyelitis

- Soft tissue swelling
 - Lytic bone destruction*
 - Periosteal reaction (formation of new bone, especially in response to #)*
- *Generally not seen on plain films until 10-12 d after onset of infection

Clinical Features

- symptoms: pain and fever
- on exam: erythema, tenderness, edema common ± abscess/draining sinus tract; impaired function/WB

Diagnosis

- see **Medical Imaging, MI23**
- workup includes: WBC and differential, ESR, CRP, blood culture, aspirate culture/bone biopsy

Table 6. Treatment of Osteomyelitis

Acute Osteomyelitis	Chronic Osteomyelitis
IV antibiotics 4-6 wk; started empirically and adjusted after obtaining blood and aspirate cultures	Surgical debridement
± surgery (I&D) for abscess or significant involvement	Antibiotics: both local (e.g. antibiotic beads) and systemic (IV)
± hardware removal (if present)	

Rapid progression of signs and symptoms (over hours) necessitates need for serial examinations

Acute osteomyelitis is a medical emergency which requires an early diagnosis and appropriate antimicrobial and surgical treatment

Most commonly affected joints in descending order
knee → hip → elbow → ankle → sternoclavicular joint

Plain Film Findings in a Septic Joint

- Early (0-3 d): usually normal; may show soft-tissue swelling or joint space widening from localized edema
- Late (4-6 d): joint space narrowing and destruction of cartilage

Serial C-reactive protein (CRP) can be used to monitor response to therapy

Does This Adult Patient Have Septic Arthritis?
JAMA 2007;297(13):1478-1488

Purpose: To review the accuracy and precision of the clinical evaluation for the diagnosis of nongonococcal bacterial arthritis.

Methods: Review of 14 studies including 6242 patients of which 653 had positive synovial culture (gold standard diagnostic tool for septic arthritis).

Results/Conclusions: Age, diabetes mellitus, rheumatoid arthritis, joint surgery, hip or knee prosthesis, skin infection, and human immunodeficiency virus type 1 infection significantly increase the probability of septic arthritis. Joint pain, history of joint swelling, and fever are useful clinical findings in identifying patients with a monoarticular arthritis who may have septic arthritis. Laboratory findings from an arthrocentesis are also required and helpful prior to Gram stain and culture. The presence of increased WBC increases the likelihood ratio (for counts <25 000/μL: LR, 0.32; 95% CI, 0.23-0.43; for counts ≥25 000/μL: LR, 2.9; 95% CI, 2.5-3.4; for counts ≥100 000/μL: LR, 28.0; 95% CI, 12.0-66.0). A polymorphonuclear cell count of ≥90% increases the LR of septic arthritis by 3.4, while a PMN cell count of <90% reduces the LR by 0.34.

Posterior Shoulder Dislocation
Up to 60-80% are missed on initial presentation due to poor physical exam and radiographs

There are 4 Joints in the Shoulder
glenohumeral, AC, sternoclavicular (SC), scapulothoracic

Septic Joint

- joint infection with progressive destruction if left untreated

Etiology

- most commonly caused by *S. aureus* in adults
- consider coagulase-negative *Staphylococcus* in patients with prior joint replacement
- consider *Neisseria gonorrhoeae* in sexually active adults and newborns
- most common route of infection is hematogenous
- risk factors: young/elderly (age >80 yr), RA, prosthetic joint, recent joint surgery, skin infection/ulcer, IV drug use, previous intra-articular corticosteroid injection, immune compromise (cancer, DM, alcoholism)

Clinical Features

- inability/refusal to bear weight, localized joint pain, erythema, warmth, swelling, pain on active and passive ROM, ± fever

Investigations

- x-ray (to rule out fracture, tumour, metabolic bone disease), ESR, CRP, WBC, blood cultures
- joint aspirate: cloudy yellow fluid, WBC >50,000 with >90% neutrophils, protein level >4.4 mg/dL, joint glucose level <60% blood glucose level, no crystals, positive Gram stain results
- listen for heart murmur (to reduce suspicion of infective endocarditis, use Duke Criteria)

Treatment

- IV antibiotics, empiric therapy (based on age and risk factors), adjust following joint aspirate C&S results
- non-operative
 - therapeutic joint aspiration, serially if necessary (if early diagnosis and joint superficial)
- operative
 - arthroscopic/open irrigation and irrigation and drainage ± decompression

Shoulder

Shoulder Dislocation

- complete separation of the glenohumeral joint; may be anterior or posterior

Investigations

- anterior dislocation X-rays: AP, trans-scapular, axillary views
- posterior dislocation X-rays: AP, trans-scapular, axillary; or CT scan

Table 7. Anterior and Posterior Shoulder Dislocation

	Anterior Shoulder Dislocation (>90%)	Posterior Shoulder Dislocation (5%)
MECHANISM	Abducted arm is externally rotated/hyperextended, or blow to posterior shoulder Involuntary, usually traumatic; voluntary, atraumatic	Adducted, internally rotated, flexed arm FOOSH 3 Es (epileptic seizure, EtOH, electrocution) Blow to anterior shoulder
CLINICAL FEATURES		
Symptoms	Pain, arm slightly abducted and externally rotated with inability to internally rotate	Pain, arm is held in adduction and internal rotation; external rotation is blocked
Shoulder Exam	“Squared off” shoulder Positive apprehension test: patient looks apprehensive with gentle shoulder abduction and external rotation to 90° as humeral head is pushed anteriorly and recreates feeling of anterior dislocation (see Figure 11) Positive relocation test: a posteriorly directed force applied during the apprehension test relieves apprehension since anterior subluxation is prevented Positive sulcus sign: presence of subacromial indentation with distal traction on humerus indicates inferior shoulder instability (see Figure 11)	Anterior shoulder flattening, prominent coracoid, palpable mass posterior to shoulder Positive posterior apprehension (“jerk”) test: with patient supine, flex elbow 90° and adduct, internally rotate the arm while applying a posterior force to the shoulder; patient will “jerk” back with the sensation of subluxation (see Figure 11) Note: the posterior apprehension test is used to test for recurrent posterior instability, NOT for acute injury
Neurovascular Exam Including	Axillary nerve: sensory patch over deltoid and deltoid contraction Musculocutaneous nerve: sensory patch on lateral forearm and biceps contraction	Full neurovascular exam as per anterior shoulder dislocation
RADIOGRAPHIC FINDINGS		
Axillary View	Humeral head is anterior	Humeral head is posterior
Trans-scapular ‘Y’ View	Humeral head is anterior to the centre of the “Mercedes-Benz” sign	Humeral head is posterior to centre of “Mercedes-Benz” sign
AP View	Sub-coracoid lie of the humeral head is most common	Partial vacancy of glenoid fossa (vacant glenoid sign) and > 6 mm space between anterior glenoid rim and humeral head (positive rim sign), humeral head may resemble a lightbulb due to internal rotation (lightbulb sign)
Hill-Sachs and Bony Bankart Lesions	± Hill-Sachs lesion: compression fracture of posterior humeral head due to forceful impaction of an anteriorly dislocated humeral head against the glenoid rim (see Figure 10) ± bony Bankart lesion: avulsion of the anterior glenoid labrum (with attached bone fragments) from the glenoid rim (see Figure 10)	± reverse Hill-Sachs lesion (75% of cases): divot in anterior humeral head ± reverse bony Bankart lesion: avulsion of the posterior glenoid labrum from the bony glenoid rim
TREATMENT	Closed reduction with IV sedation and muscle relaxation Traction-countertraction: assistant stabilizes torso with a folded sheet wrapped across the chest while the surgeon applies gentle steady traction Stimson: while patient lies prone with arm hanging over table edge, hang a 5 lb weight on wrist for 15-20 min Hippocratic method: place heel into patient’s axilla and apply traction to arm Cunningham’s method: low risk, low pain; if not successful try above methods Obtain post-reduction x-rays Check post-reduction NVS Sling x 3 wk (avoid abduction and external rotation), followed by shoulder rehabilitation (dynamic stabilizer strengthening)	Closed reduction with sedation and muscle relaxation Inferior traction on a flexed elbow with pressure on the back of the humeral head Obtain post-reduction x-rays Check post-reduction NVS Sling in abduction and external rotation x 3 wk, followed by shoulder rehabilitation (dynamic stabilizer strengthening)

Prognosis

- recurrence rate depends on age of first dislocation
- <20 yr = 65-95%; 20-40 yr = 60-70%; >40 yr = 2-4%

Specific Complications

- rotator cuff or capsular or labral tear (Bankart/SLAP lesion), shoulder stiffness
- injury to axillary nerve/artery, brachial plexus
- recurrent/unreduced dislocation (most common complication)

Shoulder passive ROM: abduction – 180°, adduction – 45°, flexion – 180°, extension – 45°, int. rotation – level of T4, ext. rotation – 40-45°

Factors Causing Shoulder Instability

- Shallow glenoid
- Loose capsule
- Ligamentous laxity

Frequency of Dislocations

- Anterior shoulder > Posterior shoulder
 - Posterior hip > Anterior hip
- The glenohumeral joint is the most commonly dislocated joint in the body since stability is sacrificed for motion

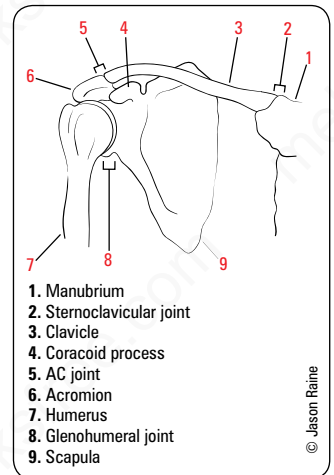

Figure 8. Shoulder joints

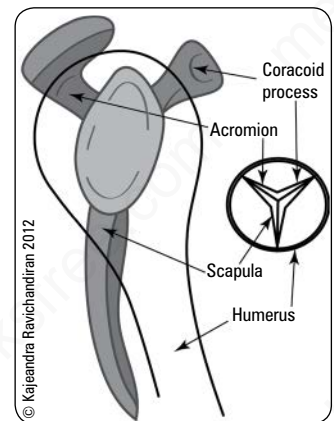

Figure 9. Mercedes-Benz

Figure 10. Posterior view of anterior dislocation causing Hill-Sachs and Bankart lesions

Figure 11. Shoulder maneuvers

Rotator Cuff Disease

- rotator cuff consists of 4 muscles that act to stabilize the humeral head within the glenoid fossa

Table 8. Rotator Cuff Muscles (SITS)

Muscle	Muscle Attachments		Nerve Supply	Muscle Function
	Proximal	Distal		
Supraspinatus	Scapula	Greater tuberosity of humerus	Suprascapular nerve	Abduction
Infraspinatus	Scapula	Greater tuberosity of humerus	Suprascapular nerve	External rotation
Teres Minor	Scapula	Greater tuberosity of humerus	Axillary nerve	External rotation
Subscapularis	Scapula	Lesser tuberosity of humerus	Subscapular nerve	Internal rotation and adduction

SPECTRUM OF DISEASE: IMPINGEMENT, TENDONITIS, MICRO OR MACRO TEARS

Etiology

- anything that leads to a narrow subacromial space
- most commonly, a relative imbalance of rotator cuff and larger shoulder muscles, allowing for superior translation and subsequent wear of the rotator cuff muscle tendons
 - glenohumeral muscle weakness leading to abnormal motion of humeral head
 - scapular muscle weakness leading to abnormal motion of acromion
- acromial abnormalities, such as congenital narrow space or osteophyte formation or Type III acromion morphology
 - outlet/subacromial impingement: “painful arc syndrome”, compression of rotator cuff tendons (primarily supraspinatus) and subacromial bursa between the head of the humerus and the undersurface of acromion, AC joint, and CA ligament
 - bursitis and tendonitis
 - rotator cuff thinning and tear if left untreated

Clinical Features

- insidious onset, but may present as an acute exacerbation of chronic disease, night pain, and difficulty sleeping on affected side
- pain worse with active motion (especially overhead); passive movement generally permitted
- weakness and loss of ROM, especially between 90°-130° (e.g. trouble with overhead activities)
- tenderness to palpation over greater tuberosity
- rule out bicep tendinosis: Speed test; SLAP lesion: O’Brien’s test

Investigations

- X-ray: AP view may show high riding humerus relative to glenoid, indicating large tear, evidence of chronic tendonitis
- MRI: coronal/sagittal, oblique and axial orientations are useful for assessing full/partial tears and tendinopathy ± arthrogram: geysers sign (injected dye leaks out of joint through rotator cuff tear)
- arthrogram: can assess full thickness tears, difficult to assess partial tears

Figure 12. Muscles of the rotator cuff

Bigliani Classification of Acromion Morphology

- Type I – flat
- Type II – curved
- Type III – hooked

Screening Out Rotator Cuff Tears*

- No night pain (SN 87.7%)
- No painful arc (SN 97.5%)
- No impingement signs (SN 97.2%)
- No weakness

*Returning to the bedside: Using the history and physical examination to identify rotator cuff tears

JAM Geri Soc 2000;48:1633-1637

Treatment

- non-operative
 - for mild (“wear”) or moderate (“tear”) cases
 - physiotherapy, NSAIDs ± steroid injection
- operative
 - indication: severe (“repair”)
 - impingement that is refractory to 2-3 mo physiotherapy and 1-2 corticosteroid injections
 - arthroscopic or open surgical repair (i.e. acromioplasty, rotator cuff repair)

Table 9. Rotator Cuff Special Tests

Test	Examination	Positive Test
Jobe’s Test	Supraspinatus: place the shoulder in 90° of abduction and 30° of forward flexion and internally rotate the arm so that the thumb is pointing toward the floor	Weakness with active resistance suggests a supraspinatus tear
Lift-off Test	Subscapularis: internally rotate arm so dorsal surface of hand rests on lower back; patient instructed to actively lift hand away from back against examiner resistance (use Belly Press Test if too painful)	Inability to actively lift hand away from back suggests a subscapularis tear
Posterior-Cuff Test	Infraspinatus and teres minor: arm positioned at patient’s side in 90° of flexion; patient instructed to externally rotate arm against the resistance of the examiner	Weakness with active resistance suggests posterior cuff tear
Neer’s Test	Rotator cuff impingement: passive shoulder flexion	Pain elicited between 130-170° suggests impingement
Hawkins-Kennedy Test	Rotator cuff impingement: shoulder flexion to 90° and passive internal rotation	Pain with internal rotation suggests impingement
Painful Arc Test	Rotator cuff tendinopathy: patient instructed to actively abduct the shoulder	Pain with abduction >90° suggests tendinopathy
Speed’s Test	Apply resistance to the forearm when the arm is in forward flexion with the elbows fully extended.	Pain in the bicipital groove
O’Brien’s Test	SLAP lesion: forward flexion of the arm to 90 degrees while keeping the arm extended. Arm is adducted 10-15 degrees. Internally rotate the arm so thumb is facing down and apply a downward force. Repeat the test with arm externally rotated	Pain or clicking in the glenohumoral joint in internal rotation but not external rotation

Ruling in Rotator Cuff Tears – 98% probability of rotator cuff tear if all 3 of the following are present:

- Supraspinatus weakness
- External rotation weakness
- Positive impingement sign(s)

Diagnosis of rotator cuff tears. *Lancet* 2001; 357:769-770

Does this Patient with Shoulder Pain have Rotator Cuff Disease? The Rational Clinical Examination Systematic Review

JAMA 2013;310:837-847

Study: 5 studies of sufficient quality including 30-203 shoulders and a prevalence of RCD ranging from 33-81%.

Results/Conclusions: Among pain provocation tests, a positive painful arc test had the greatest specificity and sensitivity (SP 81%, SN 71%)

Among strength tests, a positive external rotation lag test and internal rotation lag test were the most accurate for full-thickness tears (SP 47%, SN 94%; SP 97%, SN 83% respectively). The internal rotation lag test was therefore also the most accurate for identifying patients without a full-thickness tear. A positive drop arm test is helpful to identify patients with RCD (SN 24%, SP 93%).

Figure 13. Rotator cuff tests

Acromioclavicular Joint Pathology

- subluxation or dislocation of AC joint
- 2 main ligaments attach clavicle to scapula: AC and CC ligaments

Mechanism

- fall onto shoulder with adducted arm or direct trauma to point of shoulder

Clinical Features

- pain with adduction of shoulder and/or palpation over AC joint
- palpate step deformity between distal clavicle and acromion (with dislocation)
- limited ROM

Investigations

- X-rays: bilateral AP, Zanca view (10-15° cephalic tilt), axillary

Treatment

- non-operative
 - sling 1-3 wk, ice, analgesia, early ROM and rehabilitation
- operative
 - indication: Rockwood Class IV-VI (III if labourer or high level athlete)
 - number of different approaches involving AC/CC ligament reconstruction or screw/hook plate insertion

Pneumothorax or pulmonary contusion are potential complications of severe AC joint dislocation

Table 10. Rockwood Classification of Acromioclavicular Joint Separation

Grade	Features	Treatment
I	Joint sprain, absence of complete tear of either ligament	Non-operative
II	Complete tear of AC ligament, incomplete tear of CC ligament, without marked elevation of lateral clavicular head	Non-operative
III	Complete tear of AC and CC ligaments, >5 mm elevation at AC joint, superior aspect of acromion is below the inferior aspect of the clavicle	Most non-operative, operative if labourer or high level athlete Will heal with step deformity, although most fully functional in 4-6 mo
IV-VI	Based on the anatomical structure the displaced clavicle is in proximity to	Operative in most cases

Clavicle Fracture

- incidence: proximal (5%), middle (80%), or distal (15%) third of clavicle
- common in children (unites rapidly without complications)

Mechanism

- fall on shoulder (87%), direct trauma to clavicle (7%), FOOSH (6%)

Clinical Features

- pain and tenting of skin
- arm is clasped to chest to splint shoulder and prevent movement

Investigations

- evaluate NVS of entire upper limb
- X-ray: AP, 45° cephalic tilt (superior/inferior displacement), 45° caudal tilt (AP displacement)
- CT: useful for medial physeal fractures and sternoclavicular injury

Treatment

- medial and middle-third clavicle fractures
 - simple sling x 1-2 wk
 - early ROM and strengthening once pain subsides
 - if fracture is shortened >2 cm, consider ORIF
- distal-third clavicle fractures
 - undisplaced (with ligaments intact): sling x 1-2 wk
 - displaced (CC ligament injury): ORIF

Specific Complications (see *General Fracture Complications, OR6*)

- cosmetic bump usually only complication
- shoulder stiffness, weakness with repetitive activity
- pneumothorax, brachial plexus injuries, and subclavian vessel (all very rare)

Associated Injuries with Clavicle Fractures

- Up to 9% of clavicle fractures are associated with other fractures (most commonly rib fractures)
- Majority of brachial plexus injuries are associated with proximal third fractures

Frozen Shoulder (Adhesive Capsulitis)

- disorder characterized by progressive pain and stiffness of the shoulder, usually resolving spontaneously after 18 mo

Mechanism

- primary adhesive capsulitis
 - idiopathic, usually associated with DM
 - usually resolves spontaneously in 9-18 mo
- secondary adhesive capsulitis
 - due to prolonged immobilization
 - shoulder-hand syndrome: CRPS/RSD characterized by arm and shoulder pain, decreased motion, and diffuse swelling
 - following MI, stroke, shoulder trauma
 - poorer outcomes

Clinical Features

- gradual onset (weeks to months) of diffuse shoulder pain with:
 - decreased active AND passive ROM
 - pain worse at night and often prevents sleeping on affected side
 - increased stiffness as pain subsides: continues for 6-12 mo after pain has disappeared

Investigations

- X-ray: AP (neutral, internal/external rotation), scapular Y, axillary
 - may be normal, or may show demineralization from disease

Treatment

- freezing phase
 - active and passive ROM (physiotherapy)
 - NSAIDs and steroid injections if limited by pain
- thawing phase
 - manipulation under anesthesia and early physiotherapy
 - arthroscopy for debridement/decompression

Conditions Associated with an Increased Incidence of Adhesive Capsulitis

- Prolonged immobilization (most significant)
- Female gender
- Age >49 yr
- DM (5x)
- Cervical disc disease
- Hyperthyroidism
- Stroke
- MI
- Trauma and surgery
- Autoimmune disease

Stages of Adhesive Capsulitis

- Freezing phase: gradual onset, diffuse pain (lasts 6-9 mo)
- Frozen phase: decreased ROM impacting functioning (lasts 4-9 mo)
- Thawing phase: gradual return of motion (lasts 5-26 mo)

Humerus

Proximal Humeral Fracture

Mechanism

- young: high energy trauma (MVC)
- elderly: FOOSH from standing height in osteoporotic individuals

Clinical Features

- proximal humeral tenderness, deformity with severe fracture, swelling, painful ROM, bruising extends down arm and chest

Investigations

- test axillary nerve function (deltoid contraction and skin over deltoid)
- X-rays: AP, trans-scapular, axillary are essential
- CT scan: to evaluate for articular involvement and fracture displacement

Classification

- Neer classification is based on 4 fracture locations or 'parts'
- displaced: displacement >1 cm and/or angulation >45°
- the Neer system regards the number of displaced fractures, not the fracture line, in determining classification
- ± dislocated/subluxed: humeral head dislocated/subluxed from glenoid

Treatment

- treat osteoporosis if needed
- non-operative
 - nondisplaced: broad arm sling immobilization, begin ROM within 14 d to prevent stiffness
 - minimally displaced (85% of patients) - closed reduction with sling immobilization x 2 wk, gentle ROM
- operative
 - ORIF (anatomic neck fractures, displaced, associated dislocated glenohumeral joint)
 - hemiarthroplasty or reverse TSA may be necessary, especially in elderly

Specific Complications (see *General Fracture Complications*, OR6)

- AVN, nerve palsy (45%; typically axillary nerve), malunion, post-traumatic arthritis

Neer Classification

Based on 4 parts of humerus

- Greater Tuberosity
- Lesser Tuberosity
- Humeral Head
- Shaft

One-part fracture: any of the 4 parts with none displaced

Two-part fracture: any of the 4 parts with 1 displaced

Three-part fracture: displaced fracture of surgical neck + displaced greater tuberosity or lesser tuberosity

Four-part fracture: displaced fracture of surgical neck + both tuberosities

Anatomic neck fractures disrupt blood supply to the humeral head and AVN of the humeral head may ensue

Humeral Shaft Fracture

Mechanism

- high energy: direct blows/MVC (especially young); low energy: FOOSH, twisting injuries, metastases (in elderly)

Clinical Features

- pain, swelling, weakness \pm shortening, motion/crepitus at fracture site
- must test radial nerve function before and after treatment: look for drop wrist, sensory impairment dorsum of hand

Investigations

- X-ray: AP and lateral radiographs of the humerus, including the shoulder and elbow joints

Treatment

- in general, humeral shaft fractures are treated non-operatively
- non-operative
 - \pm reduction; can accept deformity due to compensatory ROM of shoulder
 - hanging cast (weight of arm in cast provides traction across fracture site) with collar and cuff sling immobilization until swelling subsides, then Sarmiento functional brace, followed by ROM
- operative
 - indications: see "NO CAST" (OR5), pathological fracture, "floating elbow" (simultaneous unstable humeral and forearm fractures)
 - ORIF: plating (most common), IM rod insertion, external fixation

Specific Complications (see *General Fracture Complications*, OR6)

- radial nerve palsy: expect spontaneous recovery in 3-4 mo, otherwise send for EMG
- non-union: most frequently seen in middle 1/3
- decreased ROM
- compartment syndrome

Figure 14. Fractures of the proximal humerus

Acceptable Humeral Shaft Deformities for Non-Operative Treatment

- $<20^\circ$ anterior angulation
- $<30^\circ$ varus angulation
- <3 cm of shortening

Risk of radial nerve and brachial artery injury

Distal Humeral Fracture

Mechanism

- young: high energy trauma (MVC)
- elderly: FOOSH

Clinical Features

- elbow pain and swelling
- assess brachial artery

Investigations

- X-ray: AP and lateral of humerus and elbow
- CT scan: helpful when suspecting shear fracture of capitulum or trochlea

Classification

- supracondylar, distal single column, distal bicolunar, and coronal shear fractures

Treatment

- goal is to restore ROM 30-130° flexion (unsatisfactory outcomes in 25%)
- non-operative
 - cast immobilization (in supination for lateral condyle fracture; pronation for medial condyle fractures)
- operative
 - indications: displaced, supracondylar, bicolunar
 - closed reduction and percutaneous pinning; ORIF; total elbow arthroplasty (bicolunar in elderly)

The anterior humeral line refers to an imaginary line drawn along the anterior surface of the humeral cortex that passes through the middle third of the capitulum when extended inferiorly. In subtle supracondylar fractures, the anterior humeral line is disrupted, typically passing through the anterior third of the capitulum

Elbow

Supracondylar Fracture

- subclass of distal humerus fracture: extra-articular, fracture proximal to capitulum and trochlea, usually transverse
- most common in pediatric population (peak age ~7 yr old), rarely seen in adults
- AIN (median nerve) injury commonly associated with extension type

Mechanism

- >96% are extension injuries via FOOSH (e.g. fall off monkey bars); <4% are flexion injuries

Clinical Features

- pain, swelling, point tenderness
- neurovascular injury: assess median and radial nerves, radial artery (check radial pulse)

Investigations

- X-ray: AP, lateral of elbow
 - disruption of anterior humeral line suggests supracondylar fracture
 - fat pad sign: a sign of effusion and can be indicative of occult fracture

Treatment

- reduction indications: evidence of arterial obstruction, unacceptable angulation, displaced (>50%)
- non-operative
 - nondisplaced: long arm plaster slab in 90° flexion x 3 wk
- operative
 - indications: displaced, vascular injury, open fracture
 - requires percutaneous pinning followed by limb cast with elbow flexed <90°
 - in adults, ORIF is necessary

Specific Complications (see *General Fracture Complications, OR6*)

- stiffness is most common
- brachial artery injury (kinking can occur if displaced fracture), median or ulnar nerve injury, compartment syndrome (leads to Volkmann's ischemic contracture), malalignment cubitus varus (distal fragment tilted into varus)

Radial Head Fracture

- a common fracture of the upper limb in young adults

Mechanism

- FOOSH with elbow extended and forearm pronated

Clinical Features

- marked local tenderness on palpation over radial head (lateral elbow)
- decreased ROM at elbow, ± mechanical block to forearm pronation and supination
- pain on pronation/supination

Investigations

- X-ray: enlarged anterior fat pad ("sail sign") or the presence of a posterior fat pad indicates effusion which could occur with occult radial head fractures

Table 11. Classification and Treatment of Radial Head Fractures

Mason Class	Radiographic Description	Treatment
1	Nondisplaced fracture	Elbow slab or sling x 3-5 d with early ROM
2	Displaced fracture	ORIF if: angulation >30°, involves ≥1/3 of the radial head, or if ≥3 mm of joint incongruity exists
3	Comminuted fracture	Radial head excision ± prosthesis (if ORIF not feasible)
4	Comminuted fracture with posterior elbow dislocation	Radial head excision ± prosthesis

Specific Complications (see *General Fracture Complications, OR6*)

- myositis ossificans – calcification of muscle
- recurrent instability (if MCL injured and radial head excised)

Three Joints at the Elbow

- Humeroradial joint
- Humeroulnar joint
- Radioulnar joint

Normal carrying angle of elbow is ~10° of valgus

Figure 15. X-ray of transverse displaced supracondylar fracture of humerus with elbow dislocation

Figure 16. Lateral view of elbow

Terrible Triad

- Radial head fracture
- Coronoid fracture
- Elbow dislocation

Figure 17. X-ray of fat pad sign

To avoid stiffness do not immobilize elbow joint >2-3 wk

Olecranon Fracture

Mechanism

- direct trauma to posterior aspect of elbow (fall onto the point of the elbow) or FOOSH

Clinical Features

- localized pain, palpable defect
- \pm loss of active extension due to avulsion of triceps tendon

Investigations

- X-ray: AP and lateral (require true lateral to determine fracture pattern)

Treatment

- non-operative
 - non-displaced (<2 mm, stable): cast x 3 wk (elbow in 90° flexion), then gentle ROM
- operative
 - displaced: ORIF (plate and screws or tension band wiring) and early ROM if stable

Elbow Dislocation

- third most common joint dislocation after shoulder and patella
- anterior capsule and collateral ligaments disrupted

Mechanism

- elbow hyperextension via FOOSH or valgus/supination stress during elbow flexion
- usually the radius and ulna are dislocated together, or the radial head dislocates and the ulna remains ("Monteggia")
- 80% are posterior/posterolateral, anterior are rare and usually devastating

Clinical Features

- elbow pain, swelling, deformity
- flexion contracture
- \pm absent radial or ulnar pulses

Investigations

- x-ray: AP and lateral views

Treatment

- assess NVS before reduction: brachial artery, median and ulnar nerves (can become entrapped during manipulation)
- non-operative
 - closed reduction under conscious sedation (post-reduction x-rays required)
 - Parvin's method: patient lies prone with arm hanging down; apply gentle traction downwards on wrist; as olecranon slips distally, gently lift up the arm at elbow to reduce joint
 - long-arm splint with forearm in neutral rotation and elbow in 90° flexion
 - early ROM (<2 wk)
- operative
 - indications: complex dislocation or persistent instability after closed reduction
 - ORIF

Specific Complications (see *General Fracture Complications, OR6*)

- stiffness (loss of extension), intra-articular loose body, neurovascular injury (ulnar nerve, median nerve, brachial artery), radial head fracture
- recurrent instability uncommon

Epicondylitis

- lateral epicondylitis = "tennis elbow", inflammation of the common extensor tendon as it inserts into the lateral epicondyle
- medial epicondylitis = "golfer's elbow", inflammation of the common flexor tendon as it inserts into the medial epicondyle

Mechanism

- repeated or sustained contraction of the forearm muscles/chronic overuse

Clinical Features

- point tenderness over humeral epicondyle and/or distal to it
- pain upon resisted wrist extension (lateral epicondylitis) or wrist flexion (medial epicondylitis)
- generally a self-limited condition, but may take 6-18 mo to resolve

Elbow Dislocation

The radio-capitellar line refers to an imaginary line along the longitudinal axis of the radial neck that passes through the centre of the capitellum, regardless of the degree of elbow flexion. If the radio-capitellar line does not pass through the centre of the capitellum a dislocation should be suspected

Tennis Elbow = lateral epicondylitis; pain associated with extension of wrist

Treatment

- non-operative (very good outcomes)
 - rest, ice, NSAIDs
 - use brace/strap
 - physiotherapy, stretching, and strengthening
 - corticosteroid injection
- operative
 - indication: failed 6-12 mo conservative therapy
 - percutaneous or open release of common tendon from epicondyle

**Elbow Joint Injection**

Inject at the centre of the triangle formed by the lateral epicondyle, radial head, and olecranon

Forearm

Radius and Ulna Shaft Fractures

Mechanism

- high-energy direct or indirect (MVA, fall from height, sports) trauma
- fractures usually accompanied by displacement due to high force

Clinical Features

- deformity, pain, swelling
- loss of function in hand and forearm

Investigations

- X-ray: AP and lateral of forearm ± oblique of elbow and wrist
- CT if fracture is close to joint

Treatment

- goal is anatomic reduction since imperfect alignment significantly limits forearm pronation and supination
- ORIF with plates and screws; closed reduction with immobilization usually yields poor results for displaced forearm fractures (except in children)

Specific Complications (see *General Fracture Complications, OR6*)

- soft tissue contracture resulting in limited forearm rotation – surgical release of tissue may be warranted

Monteggia Fracture

- fracture of the proximal ulna with radial head dislocation and proximal radioulnar joint injury
- more common and better prognosis in the pediatric age group when compared to adults

Mechanism

- direct blow on the posterior aspect of the forearm
- hyperpronation
- fall on the hyperextended elbow

Clinical Features

- pain, swelling, decreased rotation of forearm ± palpable lump at the radial head
- ulna angled apex anterior and radial head dislocated anteriorly (rarely the reverse deformity occurs)

Investigations

- X-ray: AP, lateral elbow, wrist and forearm

Treatment

- adults: ORIF of ulna with indirect radius reduction in 90% of patients (ORIF of radius if unsuccessful)
- splint and early post-operative ROM if elbow completely stable, otherwise immobilization in plaster with elbow flexed for 6 wk
- pediatrics: attempt closed reduction and immobilization in plaster with elbow flexed for Bado Type I-III, surgery for Type IV

Specific Complications (see *General Fracture Complications, OR6*)

- PIN: most common nerve injury; observe for 3 mo as most resolve spontaneously
- radial head instability/redislocation
- radioulnar synostosis

© Joey Trautmann 2007

Figure 18. Monteggia fracture

In all isolated ulna fractures, assess proximal radius to rule out a Monteggia fracture

**Bado Type Classification of Monteggia Fractures**

Based on the direction of displacement of the dislocated radial head, generally the same direction as the apex of the ulnar fracture

- Type I: anterior dislocation of radial head and proximal/middle third ulnar fracture (60%)
- Type II: posterior dislocation of radial head and proximal/middle third ulnar fracture (15%)
- Type III: lateral dislocation of radial head and metaphyseal ulnar fracture (20%)
- Type IV – combined: proximal fracture of the ulna and radius, dislocation of the radial head in any direction (<5%)

Nightstick Fracture

- isolated fracture of ulna without dislocation of radial head

Mechanism

- direct blow to forearm (e.g. holding arm up to protect face)

Treatment

- non-operative
 - non-displaced
 - below elbow cast (x 10 d), followed by forearm brace (~8 wk)
- operative
 - displaced
 - ORIF if >50% shaft displacement or >10° angulation

Figure 19. Nightstick fracture

Galeazzi Fracture

- fracture of the distal radial shaft with disruption of the DRUJ
- most commonly in the distal 1/3 of radius near junction of metaphysis/diaphysis

Mechanism

- hand FOOSH with axial loading of pronated forearm or direct wrist trauma

Clinical Features

- pain, swelling, deformity, and point tenderness at fracture site

Investigations

- X-ray: AP, lateral elbow, wrist, and forearm
 - shortening of distal radius >5 mm relative to the distal ulna
 - widening of the DRUJ space on AP
 - dislocation of radius with respect to ulna on true lateral

Treatment

- all cases are operative
 - ORIF of radius; afterwards, assess DRUJ stability by balloting distal ulna relative to distal radius
 - if DRUJ is stable and reducible, splint for 10-14 d with early ROM encouraged
 - if DRUJ is unstable, ORIF or percutaneous pinning with long arm cast in supination x 6 wk

For all isolated radius fractures assess DRUJ to rule out a Galeazzi fracture

Figure 20. Galeazzi fracture

Wrist

Colles' Fracture

- extra-articular transverse distal radius fracture (~2 cm proximal to the radiocarpal joint) with dorsal displacement ± ulnar styloid fracture
- most common fracture in those >40 yr, especially in women and those with osteoporotic bone

Mechanism

- FOOSH

Clinical Features

- "dinner fork" deformity
- swelling, ecchymosis, tenderness

Investigations

- X-ray: AP and lateral wrist

Treatment

- goal is to restore radial height (13 mm), radial inclination (22°), volar tilt (11°), as well as DRUJ stability and useful forearm rotation
- non-operative
 - closed reduction (think opposite of the deformity)
 - hematoma block (sterile prep and drape, local anesthetic injection directly into fracture site) or conscious sedation
 - closed reduction: 1) traction with extension (exaggerate injury), 2) traction with ulnar deviation, pronation, flexion (of distal fragment – not at wrist)
 - dorsal slab/below elbow cast for 5-6 wk
 - x-ray at 1 wk, 3 wk, and at cessation of immobilization to ensure reduction is maintained
 - obtain post-reduction films immediately; repeat reduction if necessary

Indications for surgical management of Colles' Fracture

- Displaced intra-articular fracture
- Comminuted
- Severe osteoporosis
- Dorsal angulation >5° or volar tilt >20°
- >5 mm radial shortening

ORIF Colles' Fracture if Post-Reduction Demonstrates

- Radial shortening >3 mm or,
- Dorsal tilt >10° or,
- Intra-articular displacement/step-off >2 mm

- operative
 - indication: failed closed reduction, or loss of reduction
 - percutaneous pinning, external fixation, or ORIF

Smith's Fracture

- volar displacement of the distal radius (i.e. reverse Colles' fracture)

Mechanism

- fall onto the back of the flexed hand

Investigations

- X-ray: AP and lateral wrist

Treatment

- usually unstable and needs ORIF
- if patient is poor operative candidate, may attempt non-operative treatment
 - closed reduction with hematoma block (reduction opposite of Colles')
 - long-arm cast in supination x 6 wk

Complications of Wrist Fractures

- most common complications are poor grip strength, stiffness, and radial shortening
- distal radius fractures in individuals <40 yr of age are usually highly comminuted and are likely to require ORIF
- 80% have normal function in 6-12 mo

Table 12. Early and Late Complications of Wrist Fractures

Early	Late
Difficult reduction ± loss of reduction	Malunion, radial shortening
Compartment syndrome	Painful wrist secondary to ulnar prominence
Extensor pollicis longus tendon rupture	Frozen shoulder ("shoulder-hand syndrome")
Acute carpal tunnel syndrome	Post-traumatic arthritis
Finger swelling with venous block	Carpal tunnel syndrome
Complications of a tight cast/splint	CRPS/RSD

Scaphoid Fracture

Epidemiology

- common in young men; not common in children or in patients beyond middle age
- most common carpal bone injured
- may be associated with other carpal or wrist injuries (e.g. Colles' fracture)

Mechanism

- FOOSH: impaction of scaphoid on distal radius, most commonly resulting in a transverse fracture through the waist (65%), distal (10%), or proximal (25%) scaphoid

Clinical Features

- pain with resisted pronation
- tenderness in the anatomical "snuff box", over scaphoid tubercle, and pain with long axis compression into scaphoid
- usually nondisplaced

Investigations

- X-ray: AP, lateral, scaphoid views with wrist extension and ulnar deviation
- ± CT or MRI
- bone scan rarely used
 - note: a fracture may not be radiologically evident up to 2 wk after acute injury, so if a patient complains of wrist pain and has anatomical snuff box tenderness but a negative x-ray, treat as if positive for a scaphoid fracture and repeat x-ray 2 wk later to rule out a fracture; if x-ray still negative, order CT or MRI

Treatment

- early treatment critical for improving outcomes
- non-operative
 - non-displaced (<1 mm displacement/<15° angulation): long-arm thumb spica cast x 4 wk, then short arm cast until radiographic evidence of healing is seen (2-3 mo)
- operative
 - displaced: ORIF with headless/countersink compression screw is the mainstay treatment

Figure 21. Colles' fracture and associated bony deformity

Figure 22. Normal wrist angles + wrist angles in Colles' fracture

Note the relative shortening of the radius relative to the ulna on AP view in Colles' fracture

Scaphoid Fracture Special Tests

Tender snuff box: 100% sensitivity, but 29% specific, as it is also positive with many other injuries of radial aspect of wrist with FOOSH

Specific Complications (see *General Fracture Complications, OR6*)

- most common: nonunion/malunion (use bone graft from iliac crest or distal radius with fixation to heal)
- AVN of the proximal fragment
- delayed union (recommend surgical fixation)
- scaphoid nonunion advanced collapse (SNAC) – chronic nonunion leading to advanced collapse and arthritis of wrist

Prognosis

- proximal fifth fracture: AVN rate 100%; proximal third fracture: AVN rate 33%
- waist fractures have healing rates of 80-90%
- distal third fractures have healing rates close to 100%

The proximal pole of the scaphoid receives as much as 100% of its arterial blood supply from the radial artery that enters at the distal pole. A fracture through the proximal third disrupts this blood supply and results in a high incidence of AVN/nonunion

Figure 24. Carpal bones

Fractures of the Spine

- see [Neurosurgery, NS33](#)

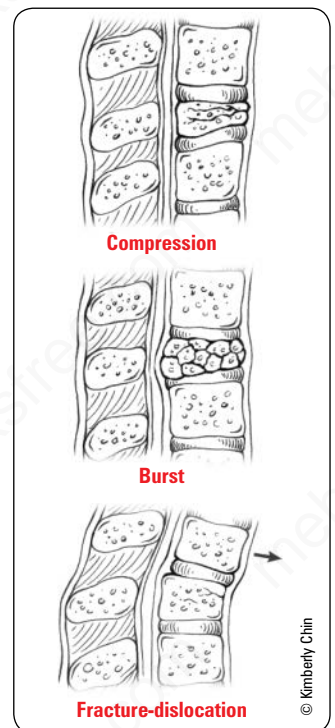

Cervical Spine

General Principles

- C1 (atlas): no vertebral body, no spinous process
- C2 (axis): odontoid = dens
- 7 cervical vertebrae; 8 cervical nerve roots
- nerve root exits above vertebra (i.e. C4 nerve root exits above C4 vertebra), C8 nerve root exits below C7 vertebra
- radiculopathy = impingement of nerve root
- myelopathy = impingement of spinal cord

Special Testing

- compression test: pressure on head worsens radicular pain
- distraction test: traction on head relieves radicular symptoms
- Valsalva test: Valsalva maneuver increases intrathecal pressure and causes radicular pain

© Kimberly Chin

Figure 26. Compression, burst, and dislocation fractures of the spine

Table 13. Cervical Radiculopathy/Neuropathy

Root	C5	C6	C7	C8
Motor	Deltoid Biceps Wrist extension	Biceps Brachioradialis	Triceps Wrist flexion Finger extension	Interossei Digital flexors
Sensory	Axillary nerve (patch over lateral deltoid)	Thumb	Index and middle finger	Ring and little finger
Reflex	Biceps	Biceps Brachioradialis	Triceps	Finger jerk

X-Rays for C-Spine

- AP spine: alignment
- AP odontoid: atlantoaxial articulation
- lateral
 - vertebral alignment: posterior vertebral bodies should be aligned (translation >3.5 mm is abnormal)
 - angulation: between adjacent vertebral bodies (>11° is abnormal)
 - disc or facet joint widening
 - anterior soft tissue space (at C3 should be ≤3 mm; at C4 should be ≤8-10 mm)
- oblique: evaluate pedicles and intervertebral foramen
- ± swimmer's view: lateral view with arm abducted 180° to evaluate C7-T1 junction if lateral view is inadequate
- ± lateral flexion/extension view: evaluate subluxation of cervical vertebrae

Differential Diagnosis of C-Spine Pain

- neck muscle strain, cervical spondylosis, cervical stenosis, RA (spondylitis), traumatic injury, whiplash, myofascial pain syndrome

C-SPINE INJURY

- see [Neurosurgery, NS35](#)

Thoracolumbar Spine

General Principles

- spinal cord terminates at conus medullaris (L1/2)
- individual nerve roots exit below pedicle of vertebra (i.e. L4 nerve root exits below L4 pedicle)

Special Tests

- straight leg raise: passive lifting of leg (30-70°) reproduces radicular symptoms of pain radiating down posterior/lateral leg to knee ± into foot
- Lasegue maneuver: dorsiflexion of foot during straight leg raise makes symptoms worse or, if leg is less elevated, dorsiflexion will bring on symptoms
- femoral stretch test: with patient prone, flexing the knee of the affected side and passively extending the hip results in radicular symptoms of unilateral pain in anterior thigh

Table 14. Lumbar Radiculopathy/Neuropathy

Root	L4	L5	S1
Motor	Quadriceps (knee extension + hip adduction) Tibialis anterior (ankle inversion + dorsiflexion)	Extensor hallucis longus Gluteus medius (hip abduction)	Peroneus longus + brevis (ankle eversion) Gastrocnemius + soleus (plantar flexion)
Sensory	Medial malleolus	1st dorsal webspace and lateral leg	Lateral foot
Screening Test	Squat and Rise	Heel Walking	Walking on Toes
Reflex	Knee (patellar)	Medial hamstring*	Ankle (Achilles)
Test	Femoral stretch	Straight leg raise	Straight leg raise

*Unreliable

Differential Diagnosis of Back Pain

1. mechanical or nerve compression (>90%)
 - degenerative (disc, facet, ligament)
 - peripheral nerve compression (disc herniation)
 - spinal stenosis (congenital, osteophyte, central disc)
 - cauda equina syndrome
2. others (<10%)
 - neoplastic (primary, metastatic, multiple myeloma)
 - infectious (osteomyelitis, TB)
 - metabolic (osteoporosis)
 - traumatic fracture (compression, distraction, translation, rotation)
 - spondyloarthropathies (ankylosing spondylitis)
 - referred (aorta, renal, ureter, pancreas)

DEGENERATIVE DISC DISEASE

- loss of vertebral disc height with age resulting in
 - bulging and tears of annulus fibrosus
 - change in alignment of facet joints
 - osteophyte formation

Mechanism

- compression over time with age

Clinical Features

- axial back pain without radicular symptoms
- pain worse with axial loading and flexion
- negative straight leg raise

Investigations

- X-ray, MRI, provocative discography

Treatment

- non-operative
 - staying active with modified activity
 - back strengthening
 - NSAIDs
 - do not treat with opioids; no proven efficacy of spinal traction or manipulation
- operative – rarely indicated
 - decompression ± fusion
 - no difference in outcome between non-operative and surgical management at 2 yr

SPINAL STENOSIS

- narrowing of spinal canal <10 mm
- congenital (idiopathic, osteopetrosis, achondroplasia) or acquired (degenerative, iatrogenic – post spinal surgery, ankylosing spondylosis, Paget’s disease, trauma)

Clinical Features

- ± bilateral back and leg pain
- neurogenic claudication
- ± motor weakness
- normal back flexion; difficulty with back extension (Kemp sign)
- positive straight leg raise, pain not worse with Valsalva

Investigations

- CT/MRI reveals narrowing of spinal canal, but gold standard = CT myelogram

Treatment

- non-operative
 - vigorous physiotherapy (flexion exercises, stretch/strength exercises), NSAIDs, lumbar epidural steroids
- operative
 - indication: non-operative failure >6 mo
 - decompressive surgery

Table 15. Differentiating Claudication

	Neurogenic	Vascular
Aggravation	With standing or exercise Walking distance variable	Walking set distance
Alleviation	Change in position (usually flexion, sitting, lying down)	Stop walking
Time	Relief in ~10 min	Relief in ~2 min
Character	Neurogenic ± neurological deficit	Muscular cramping

MECHANICAL BACK PAIN

- back pain NOT due to prolapsed disc or any other clearly defined pathology

Clinical Features

- dull backache aggravated by activity and prolonged standing
- morning stiffness
- no neurological signs

Treatment

- symptomatic (analgesics, physiotherapy)
- prognosis: symptoms may resolve in 4-6 wk, others become chronic

Cauda equina syndrome and ruptured aortic aneurysms are causes of low back pain that are considered surgical emergencies

LUMBAR DISC HERNIATION

- tear in annulus fibrosus allows protrusion of nucleus pulposus, causing either a central, posterolateral, or lateral disc herniation, most commonly at L5-S1 > L4-5 > L3-4
- 3:1 male to female
- only 5% become symptomatic
- usually a history of flexion-type injury

Clinical Features

- back dominant pain (central herniation) or leg dominant pain (lateral herniation)
- tenderness between spinous processes at affected level
- muscle spasm ± loss of normal lumbar lordosis
- neurological disturbance is segmental and varies with level of central herniation
 - motor weakness (L4, L5, S1)
 - diminished reflexes (L4, S1)
 - diminished sensation (L4, L5, S1)
- positive straight leg raise
- positive contralateral SLR
- positive Lasegue and Bowstring sign
- cauda equina syndrome (present in 1-10%): surgical emergency

Investigations

- X-ray, MRI, consider a post-void residual volume to check for urinary retention; post-void >100 mL should heighten suspicion for cauda equina syndrome

Treatment

- non-operative
 - symptomatic
 - ♦ extension protocol
 - ♦ NSAIDS
- operative
 - indication: progressive neurological deficit, failure of symptoms to resolve within 3 mo, or cauda equina syndrome due to central disc herniation
 - surgical discectomy
- prognosis
 - 90% of patients improve in 3 mo with non-operative treatment

Figure 27. Disc herniation causing nerve root compression

Neurogenic claudication is position dependent; vascular claudication is exercise dependent

MRI abnormalities (e.g. spinal stenosis, disc herniation) are quite common in both asymptomatic and symptomatic individuals and are not necessarily an indication for intervention without clinical correlation

Table 16. Types of Low Back Pain

	Mechanical Back Pain		Direct Nerve Root Compression	
	Disc Origin	Facet Origin	Spinal Stenosis	Root Compression
Pain Dominance	Back	Back	Leg	Leg
Aggravation	Flexion	Extension, standing, walking	Exercise, extension, walking, standing	Flexion
Onset	Gradual	More sudden	Congenital or acquired	Acute leg ± back pain
Duration	Long (weeks, months)	Shorter (days, weeks)	Acute or chronic history (weeks to months)	Short episodes Attacks (minutes)
Treatment	Relief of strain, exercise	Relief of strain, exercise	Relief of strain, exercise + surgical decompression if progressive or severe deficit	Relief of strain, exercise + surgical decompression if progressive or severe deficit

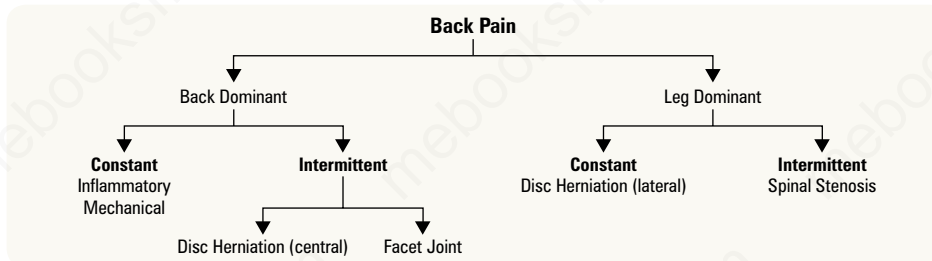

Figure 28. Approach to back pain

SPONDYLOLYSIS

Definition

- defect in the pars interarticularis with no movement of the vertebral bodies

Mechanism

- trauma: gymnasts, weightlifters, backpackers, loggers, labourers

Red Flags for

BACK PAIN

- Bowel or bladder dysfunction
- Anesthesia (saddle)
- Constitutional symptoms/malignancy
- Chronic disease
- Paresthesias
- Age >50 yr
- IV drug use
- Neuromotor deficits

Sciatica

- Most common symptom of radiculopathy (L4-S3)
- Leg dominant, constant, burning pain
- Pain radiates down leg ± foot
- Most common cause = disc herniation

Clinical Features

- activity-related back pain, pain with unilateral extension (Micheli's test)

Investigations

- oblique X-ray: "collar" break in the "Scottie dog's" neck
- bone scan
- CT scan

Treatment

- non-operative
 - activity restriction, brace, stretching exercise

ADULT ISTHMIC SPONDYLOLISTHESIS

Definition

- defect in pars interarticularis causing a forward translation or slippage of one vertebra on another, usually at L5-S1, less commonly at L4-5

Mechanism

- congenital (children), degenerative (adults), traumatic, pathological, teratogenic

Clinical Features

- lower back pain radiating to buttocks relieved with sitting
- neurogenic claudication
- L5 radiculopathy
- Meyerding Classification (percentage of slip)

Investigations

- X-ray (AP, lateral, oblique flexion-extension views), MRI

Treatment

- non-operative
 - activity restriction, bracing, NSAIDs
- operative

Table 17. Classification and Treatment of Spondylolisthesis

Class	Percentage of Slip	Treatment
1	0-25%	Symptomatic operative fusion only for intractable pain
2	25-50	Same as above
3	50-75	Decompression for spondylolisthesis and spinal fusion
4	75-100	Same as above
5	>100	Same as above

Specific Complications

- may present as cauda equina syndrome due to roots being stretched over the edge of L5 or sacrum

Figure 29. Spondylolysis, spondylolisthesis

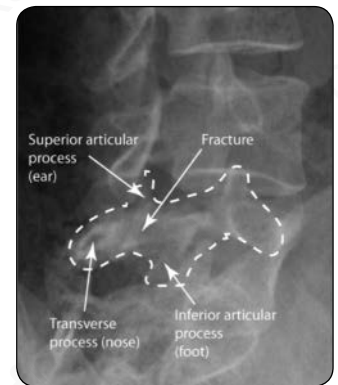

Figure 30. "Scottie dog" fracture

Pelvis

Pelvic Fracture

Mechanism

- young: high energy trauma, either direct or by force transmitted longitudinally through the femur
- elderly: fall from standing height, low energy trauma
- lateral compression, vertical shear, or anteroposterior compression fractures

Clinical Features

- pain, inability to bear weight
- local swelling, tenderness
- deformity of lower extremity
- pelvic instability

Figure 31. Pelvic columns

Investigations

- X-ray: AP pelvis, inlet and outlet views, Judet views (obturator and iliac oblique for acetabular fracture)
 - 6 cardinal radiographic lines of the acetabulum: ilioischial line, iliopectineal line, teardrop, roof, posterior rim, anterior rim
- CT scan useful for evaluating posterior pelvic injury and acetabular fracture
- assess genitourinary injury (rectal exam, vaginal exam, hematuria, blood at urethral meatus)
 - if involved, the fracture is considered an open fracture

Classification

Table 18. Tile Classification of Pelvic Fractures

Type	Stability	Description
A	Rotationally stable Vertically stable	A1: fracture not involving pelvic ring (i.e. avulsion or iliac wing fracture) A2: minimally displaced fracture of pelvic ring (e.g. ramus fracture) A3: transverse sacral fracture
B	Rotationally unstable Vertically stable	B1: open book (external rotation) B2: lateral compression – ipsilateral B2-1: with anterior ring rotation/displacement through ipsilateral rami B2-2: with anterior ring rotation/displacement through non-ipsilateral rami (bucket-handle) B3: bilateral
C	Rotationally unstable Vertically unstable	C1: unilateral C1-1: iliac fracture, C1-2: sacroiliac fracture-dislocation C1-3: sacral fracture C2: bilateral with 1 side type B and 1 side type C C3: bilateral both sides type C

Treatment

- ABCDEs
- non-operative treatment: protected weight bearing
 - indication: stable fracture
- emergency management
 - IV fluids/blood
 - pelvic binder/sheeting
 - external fixation vs. emergent angiography/embolization
 - ± laparotomy (if FAST/DPL positive)
- operative treatment: ORIF
 - indications
 - ♦ unstable pelvic ring injury
 - ♦ disruption of anterior and posterior SI ligament
 - ♦ symphysis diastasis >2.5 cm
 - ♦ vertical instability of the posterior pelvis
 - ♦ open fracture

Specific Complications (see *General Fracture Complications, OR6*)

- hemorrhage (**life-threatening**)
- injury to rectum or urogenital structures
- obstetrical difficulties, sexual and voiding dysfunction
- persistent SI joint pain
- post-traumatic arthritis of the hip with acetabular fractures
- high risk of DVT/PE

Possible Radiological Findings

- Pubic rami fractures: superior/inferior
- Pubic symphysis diastasis: common in AP compression (N=5 mm)
- Sacral fractures: common in lateral compression
- SI joint diastasis: common in AP compression (N=1-4 mm)
- Disrupted anterior column (iliopectineal line) or posterior column (ilioischial line)
- “Teardrop” displacement: acetabular fracture
- Iliac, ischial avulsion fractures
- Displacement of the major fragment: superior (VS), open book (APC), bucket handle (LC)

Figure 32. Tile classification of pelvic fractures

Hip

Hip Dislocation

- full trauma survey (see *Emergency Medicine, Patient Assessment/Management, ER2*)
- examine for neurovascular injury PRIOR to open or closed reduction
- reduce hip dislocations within 6 h to decrease risk of AVN of the femoral head
- hip precautions (no extreme hip flexion, adduction, internal or external rotation) for 6 wk post-reduction
- see *Hip Dislocation Post-Total Hip Arthroplasty, OR29*

ANTERIOR HIP DISLOCATION

- mechanism: posteriorly directed blow to knee with hip widely abducted
- clinical features: shortened, abducted, externally rotated limb
- treatment
 - closed reduction under conscious sedation/GA
 - post-reduction CT to assess joint congruity

Up to 50% of patients with hip dislocations suffer fractures elsewhere at the time of injury

Figure 33. Rochester method

POSTERIOR HIP DISLOCATION

- most frequent type of hip dislocation
- mechanism: severe force to knee with hip flexed and adducted
 - e.g. knee into dashboard in MVC
- clinical features: shortened, adducted, internally rotated limb
- treatment
 - closed reduction under conscious sedation/GA only if no associated femoral neck fracture or ipsilateral displacement
 - ORIF if unstable, intra-articular fragments, or posterior wall fracture
 - post-reduction CT to assess joint congruity and fractures
 - if reduction is unstable, put in traction x 4-6 wk

COMPLICATIONS FOR ALL HIP DISLOCATIONS

- post-traumatic OA
- AVN of femoral head
- fracture of femoral head, neck, or shaft
- sciatic nerve palsy in 25% (10% permanent)
- HO
- thromboembolism – DVT/PE

Rochester Method to Reduce Posterior Dislocations

- Patient lying supine with hip and knee flexed on injured side
- Surgeon stands on patient's injured side
- Surgeon passes one arm under patient's flexed knee, reaching to place that hand on patient's other knee (thus supporting patient's injured leg)
- With other hand, surgeon grasps patient's ankle on injured side, applying traction, while assistant stabilizes pelvis
- Reduction via traction, internal rotation, then external rotation once femoral head clears acetabular rim

Hip Fracture

General Features

- acute onset of hip pain
- unable to weight-bear
- shortened and externally-rotated leg
- painful ROM

Figure 34. Subcapital, intertrochanteric, and subtrochanteric hip fractures

Table 19. Overview of Hip Fractures

Fracture Type	Definition	Mechanism	Special Clinical Features	Investigations	Treatment	Complications
Femoral Neck (Subcapital)	Intracapsular (See Garden Classification, Table 20)	Young: MVC, fall from height Elderly: fall from standing, rotational force	Same as general	X-Ray: AP hip, AP pelvis, cross table lateral hip	See Table 20	DVT, non-union, AVN, dislocation
Intertrochanteric Stable: intact posteromedial cortex Unstable: non-intact posteromedial cortex	Extracapsular fracture including the greater and lesser trochanters and transitional bone between the neck and shaft	Same as femoral neck fracture Direct or indirect force transmitted to the intertrochanteric area	Ecchymosis at back of upper thigh	X-Ray: AP pelvis, AP/lateral hip	Closed reduction under fluoroscopy then dynamic hip screw or IM nail	DVT, varus displacement of proximal fragment, malrotation, non-union, failure of fixation device
Subtrochanteric	Fracture begins at or below the lesser trochanter and involves the proximal femoral shaft	Young: high energy trauma Elderly: osteopenic bone + fall, pathological fracture	Ecchymosis at back of upper thigh	X-Ray: AP pelvis, AP/lateral hip and femur	Closed/open under fluoroscopy, then plate fixation or IM nail	Malalignment, non-union, wound infection

X-Ray Features of Subcapital Hip Fractures

- Disruption of Shenton's line (a radiographic line drawn along the upper margin of the obturator foramen, extending along the inferomedial side of the femoral neck)
- Altered neck-shaft angle (normal is 120-130°)

DVT Prophylaxis in Hip Fractures

LMWH (i.e. enoxaparin 40 mg SC bid), fondaparinux, low dose heparin on admission, do not give < 12 h before surgery

AVN of Femoral Head

- Distal to proximal blood supply along femoral neck to head (medial and lateral femoral circumflex arteries)
- Susceptible to AVN if blood supply disrupted
- Etiology: femoral neck fracture, chronic systemic steroid use, SCFE, Legg-Calvé-Perthes, SLE, RA

Comparative Effectiveness of Pain Management Interventions for Hip Fracture: A Systematic Review

Study: Randomized controlled trials (RCTs); nonrandomized controlled trials (non-RCTs); and cohort studies of pain management techniques in older adults after acute hip fracture.
Conclusions: Nerve blockade seems to be effective in reducing acute pain after hip fracture. Low-level evidence suggests that preoperative traction does not reduce acute pain. Evidence was insufficient on the benefits and harms of many other interventions.

Table 20. Garden Classification of Femoral Neck Fractures

Type	Displacement	Extent	Alignment	Trabeculae	Treatment
I	None	"Incomplete"	Valgus or neutral	Malaligned	Internal fixation to prevent displacement (valgus impacted fracture)
II	None	Complete	Neutral	Aligned	Internal fixation to prevent displacement
III	Some	Complete	Varus	Malaligned	Young: ORIF Elderly: hemi-/total hip arthroplasty
IV	Complete	Complete	Varus	Aligned	Young: ORIF Elderly: hemi-/total hip arthroplasty

**Figure 35. Garden classification of femoral neck fractures**

Arthritis of the Hip

Etiology

- OA, inflammatory arthritis, post-traumatic arthritis, late effects of congenital hip disorders, or septic arthritis

Clinical Features

- pain (groin, medial thigh) and stiffness aggravated by activity, better with rest in OA
- RA: morning stiffness >1 h, multiple joint swelling, hand nodules
- decreased ROM (internal rotation is lost first)
- crepitus
- effusion
- ± fixed flexion contracture leading to apparent limb shortening (Thomas test)
- ± Trendelenburg sign

Investigations

- X-ray: weight-bearing views of affected joint
 - OA: joint space narrowing, subchondral sclerosis, subchondral cysts, osteophytes
- RA: osteopenia, erosion, joint space narrowing, subchondral cysts
- blood work: ANA, RF

Treatment

- non-operative
 - weight reduction, activity modification, physiotherapy, analgesics, walking aids
- operative
 - indication: advanced disease
 - realign = osteotomy; replace = arthroplasty; fuse = arthrodesis
- complications with arthroplasty: component loosening, dislocation, HO, thromboembolism, infection, neurovascular injury, limb length discrepancy
- arthroplasty is standard of care in most patients with hip arthritis

Hip Dislocation Post-Total Hip Arthroplasty

- occurs in 1-4% of primary THA and 10-16% of revision THAs
- risk factors: neurological impairment, post-traumatic arthritis, revision surgery, substance abuse

Mechanism

- THA that is unstable when hip is flexed, adducted, and internally rotated, or extended and externally rotated (avoid flexing hip >90° or crossing legs for ~6 wk after surgery)

Investigations

- X-ray: AP pelvis, AP and lateral hip

Treatment

- non-operative
 - closed reduction: external abduction splint to prevent hip adduction (most often)
- operative
 - indication: 2 or more dislocations with evidence of polyethylene wear, malalignment, hardware failure
 - revision THA
 - conversion to hemiarthroplasty with a larger femoral head
 - resection arthroplasty is a last resort

Complications

- sciatic nerve palsy in 25% (10% permanent)
- HO
- infection

**DVT Prophylaxis in Elective THA**

(continue 10-35 d post-operative)
Fondaparinux, low molecular weight heparin, or warfarin

Femur

Femoral Diaphysis Fracture

Mechanism

- high energy trauma (MVC, fall from height, gunshot wound)
 - pathologic as a result of malignancy, osteoporosis, bisphosphonate use
- in children, can result from low energy trauma (spiral fracture)

Clinical Features

- shortened, externally rotated leg (if fracture displaced)
- inability to weight-bear
- often open injury, always a Gustilo III (Table 5)
- Winquist and Hansen classification

Investigations

- X-ray: AP pelvis, AP/lateral hip, femur, knee

Treatment

- non-operative (uncommon)
 - indication: non-displaced femoral shaft fractures in co-morbid patients
 - long leg cast
- operative
 - ORIF with antegrade IM nail (most common) or retrograde IM nail; external fixator for unstable patients, open fractures, or highly vascular areas; or plate and screws for open growth plates within 24 h
 - early mobilization and strengthening

Complications

- blood loss
- fat embolism leading to ARDS
- extensive soft tissue damage
- ipsilateral hip dislocation/fracture (2-6%)
- nerve injury

It is important to rule out ipsilateral femoral neck fracture, as they occur in 2-6% of femoral diaphysis fractures and are reportedly missed in 19-31% of cases

Distal Femoral Fracture

- fractures from articular surface to 5 cm above metaphyseal flare

Mechanism

- direct high energy force or axial loading
- three types: extra articular, partial articular, complete articular

Clinical Features

- extreme pain
- knee effusion (hemarthrosis)
- neurovascular deficits can occur with displaced fracture

Investigations

- X-ray: AP, lateral
- CT, angiography if diminished pulses

Figure 36. Distal femoral fractures

Treatment

- non-operative (uncommon)
 - indication: non-displaced extra-articular fracture
 - ♦ hinged knee brace
- operative
 - indication: displaced fracture, intra-articular fracture, non-union
 - ♦ ORIF or retrograde IM nail if supracondylar and non-comminuted
 - ♦ early mobilization and strengthening

Specific Complications (see *General Fracture Complications*, OR6)

- femoral artery tear
- popliteal artery injury
- nerve injury
- extensive soft tissue injury
- angulation deformities

1. Posterior horn of lateral meniscus
2. Anterior horn of lateral meniscus
3. PCL
4. ACL
5. Posterior horn of medial meniscus
6. Anterior horn of medial meniscus

© Jenn Platt 2004

Figure 37. Diagram of the right tibial plateau

Figure 38. Knee ligament and anatomy

Knee

Evaluation of Knee

Common Complaints

- locking, instability, and swelling
 - torn meniscus/loose body in joint
- pseudo-locking: limited ROM without mechanical block
 - effusion, muscle spasm after injury, arthritis
- painful clicking (audible)
 - torn meniscus
- giving way: instability
 - cruciate ligament or meniscal tear, patellar dislocation

Special Tests of the Knee

- **anterior and posterior drawer tests (Figure 39)**
 - demonstrate ACL and PCL, respectively
 - ♦ knee flexed at 90°, foot immobilized, hamstrings released
 - ♦ if able to sublax tibia anteriorly (anterior drawer test), then ACL may be torn
 - ♦ if able to sublax tibia posteriorly (posterior drawer test), then PCL may be torn
 - ♦ anterior drawer test for ACL: 3.8 positive likelihood ratio, 0.30 negative likelihood ratio
- **Lachman test**
 - demonstrates torn ACL
 - hold knee in 10-20° flexion, stabilizing the femur
 - try to sublax tibia anteriorly on femur
 - similar to anterior drawer test, more reliable due to less muscular stabilization
 - for ACL: 25.0 positive likelihood ratio, 0.1 negative likelihood ratio
- **pivot shift sign**
 - demonstrates torn ACL
 - start with the knee in extension
 - internally rotate foot, slowly flex knee while palpating and applying a valgus force
 - if incompetent ACL, tibia will sublax anteriorly on femur at start of maneuver. During flexion, the tibia will reduce and externally rotate about the femur (the "pivot")
 - reverse pivot shift (start in flexion, externally rotate, apply valgus and extend knee) suggests torn PCL
 - composite assessment for ACL: 25.0 positive likelihood ratio, 0.04 negative likelihood ratio
 - composite assessment for PCL: 21.0 positive likelihood ratio, 0.05 negative likelihood ratio
- **posterior sag sign**
 - demonstrates torn PCL
 - may give a false positive anterior draw sign
 - flex knees and hips to 90°, hold ankles and knees
 - view from the lateral aspect
 - if one tibia sags posteriorly compared to the other, its PCL is torn
- **collateral ligament stress test**
 - palpate ligament for "opening" of joint space while testing
 - with knee in full extension, apply valgus force to test MCL, apply varus force to test LCL
 - repeat tests with knee in 20° flexion to relax joint capsule
 - opening in 20° flexion due to MCL damage only
 - opening in 20° of flexion and full extension is due to MCL, cruciate, and joint capsule damage
- **Thessaly test**
 - demonstrates meniscal tear
 - patient stands flat footed on one leg while the examiner provides his or her hands for balance. The patient then flexes the knee to 20° and rotates the femur on the tibia medially and laterally three times while maintaining the 20° flexion

Figure 39. Anterior and posterior drawer test

6 Degrees of Freedom of the Knee

- Flexion and extension
- External and internal rotation
- Varus and valgus angulation
- Anterior and posterior glide
- Medial and lateral shift
- Compression and distraction

On physical exam of the knee, do not forget to evaluate the hip

- positive for a meniscal tear if the patient experiences medial or lateral joint line discomfort
- for medial meniscus: 29.67 positive likelihood ratio, 0.11 negative likelihood ratio
- for lateral meniscus: 23.0 positive likelihood ratio, 0.083 negative likelihood ratio
- **tests for meniscal tear**
 - joint line tenderness
 - ♦ joint line pain when palpated
 - ♦ palpate one side at a time and watch patient's eyes
 - ♦ for meniscal tear: 0.9 positive likelihood ratio, 1.1 negative likelihood ratio
 - crouch compression test
 - ♦ joint line pain when squatting (anterior pain suggests patellofemoral pathology)
 - McMurray's test (Figure 40)
 - ♦ with knee in flexion, palpate joint line for painful "pop/click"
 - ♦ lateral meniscus tear exam: internally rotate foot, varus stress, and extend knee
 - ♦ medial meniscus tear exam: externally rotate foot, valgus stress, and extend knee
 - ♦ for meniscal tear: 1.3 positive likelihood ratio, 0.8 negative likelihood ratio
 - composite assessment for meniscal tears: 2.7 positive likelihood ratio, 0.4 negative likelihood ratio

X-Rays

- AP standing, lateral
- skyline: tangential view with knees flexed at 45° to see patellofemoral joint
- 3-foot standing view: useful in evaluating leg length and varus/valgus alignment
- Ottawa Knee Rules (see [Emergency Medicine, ER16](#))

Figure 40. McMurray test

Cruciate Ligament Tears

- ACL tear much more common than PCL tear

Table 21. Comparison of ACL and PCL Injuries

	Anterior Cruciate Ligament	Posterior Cruciate Ligament
Anatomy	From medial wall of lateral femoral condyle to the anteromedial and posterolateral intercondyloid eminence of the tibial plateau	Lateral wall of medial femoral condyle to posterior intercondyloid eminence of the tibial plateau
Mechanism	Sudden deceleration Hyperextension and internal rotation of tibia on femur (i.e. "plant and turn")	Sudden posterior displacement of tibia when knee is flexed or hyperextended (e.g. dashboard MVC injury)
History	Audible "pop" Immediate swelling Knee "giving way" Inability to continue activity	Audible "pop" Immediate swelling Pain with push off Cannot descend stairs
Physical	Effusion (hemarthrosis) Posterolateral joint line tenderness Positive anterior drawer Positive Lachmann Pivot shift Test for MCL, meniscal injuries	Effusion (hemarthrosis) Anteromedial joint line tenderness Positive posterior drawer Reverse pivot shift Other ligamentous, bony injuries
Treatment	Stable knee with minimal functional impairment: immobilization 2-4 wk with early ROM and strengthening High demand lifestyle: ligament reconstruction	Unstable knee or young person/high-demand lifestyle: ligament reconstruction

Figure 41. T1 MRI of torn ACL and PCL

Collateral Ligament Tears

Mechanism

- valgus force to knee = MCL tear
- varus force to knee = LCL tear

Clinical Features

- swelling/effusion
- tenderness above and below joint line medially (MCL) or laterally (LCL)
- joint laxity with varus or valgus force to knee
 - laxity with endpoint suggests partial tear
 - laxity with no endpoint suggests a complete tear
- test for other injuries (e.g. O'Donoghue's unhappy triad), common peroneal nerve injury

Investigations

- x-ray: AP and lateral; MRI

O'Donoghue's Unhappy Triad

- ACL rupture
- MCL rupture
- Meniscal damage (medial and/or lateral)

Treatment

- non-operative
 - partial tear: immobilization x 2-4 wk with early ROM and strengthening
 - complete tear: immobilization at 30° flexion
- operative
 - indication: multiple ligamentous injuries
 - surgical repair of ligaments

Partial ligamentous tears are much more painful than complete ligamentous tears

Meniscal Tears

- medial tear much more common than lateral tear

Mechanism

- twisting force on knee when it is partially flexed (e.g. stepping down and turning)
- requires moderate trauma in young person, but only mild trauma in elderly due to degeneration

Clinical Features

- immediate pain, difficulty weight-bearing, instability, and clicking
- increased pain with squatting and/or twisting
- effusion (hemarthrosis) with insidious onset (24-48 h after injury)
- joint line tenderness medially or laterally
- locking of knee (if portion of meniscus mechanically obstructing extension)

Investigations

- MRI, arthroscopy

Treatment

- non-operative
 - indication: not locked
 - ROM and strengthening (NSAIDs)
- operative
 - indication: locked or failed non-operative treatment
 - arthroscopic repair/partial meniscectomy

Meniscal repair is done if tear is peripheral with good vascular supply, is a longitudinal tear and 1-4 cm in length

Partial meniscectomy is done with tears not amenable to repair (complex, degenerative, radial)

**Tissue Sources for ACL Reconstruction**

- Hamstring
- Middle 1/3 patellar tendon (bone-patellar-bone)
- Allograft (e.g. cadaver)

Quadriceps/Patellar Tendon Rupture

Mechanism

- sudden forceful contraction of quadriceps during an attempt to stop
- more common in obese patients and those with pre-existing degenerative changes in tendon
 - DM, SLE, RA, steroid use, renal failure on dialysis

Clinical Features

- inability to extend knee or weight-bear
- possible audible “pop”
- patella in lower or higher position with palpable gap above or below patella, respectively
- may have an effusion

Investigations

- ask patient to straight leg raise (unable with complete rupture)
- knee X-ray to rule out patellar fracture, MRI to distinguish between complete and partial tears
- lateral view: patella alta with patella tendon rupture, patella baja (infera) with quadriceps tendon rupture

Treatment

- non-operative
 - indication: incomplete tears with preserved extension of knee
 - immobilization in brace
- operative
 - indication: complete ruptures with loss of extensor mechanism
- early surgical repair: better outcomes compared with delayed repair (>6 wk post-injury)
- delayed repair complicated by quadriceps contracture, patella migration, and adhesions

Patella alta = high riding patella
Patella baja (infera) = low riding patella

Dislocated Knee

Mechanism

- high energy trauma
- by definition, caused by tears of multiple ligaments

Clinical Features

- classified by relation of tibia with respect to femur
 - anterior, posterior, lateral, medial, rotary
- knee instability
- effusion
- pain
- ischemic limb
- Schenck classification

Investigations

- X-ray: AP, lateral, skyline
- associated radiographic findings include tibial plateau fracture dislocations, proximal fibular fractures, and avulsion of fibular head
- ABI (abnormal if <0.9)
- arteriogram or CT angiogram if abnormal vascular exam (such as abnormal pedal pulses)

Treatment

- urgent closed reduction
 - complicated by interposed soft tissue
- assessment of peroneal nerve, tibial artery, and ligamentous injuries
- emergent operative repair if vascular injury, open fracture or dislocation, non-reducible dislocation, compartment syndrome
- knee immobilization x 6-8 wk

Specific Complications

- high incidence of associated injuries
- popliteal artery tear
- peroneal nerve injury
- capsular tear
- chronic: instability, stiffness, post-traumatic arthritis

Schenck Classification

- Type 1: single ligament injury (ACL or PCL)
- Type 2: Injury to ACL and PCL
- Type 3: Injury to ACL, PCL and either MCL or LCL
- Type 4: Injury to ACL, PCL, MCL, LCL
- Type 5: Multiligamentous injury with periarticular fracture

Patella

Patellar Fracture

Mechanism

- direct blow to the patella: fall, MVC (dashboard)
- indirect trauma by sudden flexion of knee against contracted quadriceps

Clinical Features

- marked tenderness
- inability to extend knee or straight leg raise
- proximal displacement of patella
- patellar deformity
- \pm effusion/hemarthrosis

Investigations

- X-rays: AP, lateral, skyline
- do not confuse with bipartite patella: congenitally unfused ossification centres with smooth margins on X-ray at superolateral corner

Treatment

- non-operative
 - indication: non-displaced (step-off $<2-3$ mm and fracture gap $<1-4$ mm)
 - ♦ straight leg immobilization 1-4 wk with hinged knee brace, weight bearing as tolerated
 - ♦ progress in flexion after 2-3 wk
 - ♦ physiotherapy: quadriceps strengthening when pain has subsided
- operative
 - indication: displaced (>2 mm), comminuted, disrupted extensor mechanism
 - ORIF; if comminuted may require partial/complete patellectomy
- goal: restore extensor mechanism with maximal articular congruency

© Julie Saunders 2003

Figure 42. Types of patellar fractures

Complications

- Symptomatic wiring
- Loss of reduction
- Osteonecrosis (proximal fragment)
- Hardware failure
- Knee stiffness
- Nonunion
- Infection

Patellar Dislocation

Mechanism

- usually a non-contact twisting injury
- lateral displacement of patella after contraction of quadriceps at the start of knee flexion in an almost straight knee joint
- direct blow, e.g. knee/helmet to knee collision

Risk Factors

- young, female
- obesity
- high-riding patella (patella alta)
- genu valgus
- Q-angle (quadriceps angle) $\geq 20^\circ$
- shallow intercondylar groove
- weak vastus medialis
- tight lateral retinaculum
- ligamentous laxity (Ehlers-Danlos)

Clinical Features

- knee catches or gives way with walking
- severe pain, tenderness anteromedially from rupture of capsule
- weak knee extension or inability to extend leg unless patella reduced
- positive patellar apprehension test
 - passive lateral translation results in guarding and patient apprehension
- often recurrent, self-reducing
- concomitant MCL injury
- increased Q-angle
- J-sign

Investigations

- X-rays: AP, lateral, skyline view of patella
- check for fracture of medial patella (most common) and lateral femoral condyle

Treatment

- non-operative first
 - NSAIDs, activity modification, and physical therapy
 - short-term immobilization for comfort, then 6 wk controlled motion
 - progressive weight bearing and isometric quadriceps strengthening
- operative
 - indication: if recurrent or if loose bodies present
 - surgical tightening of medial capsule and release of lateral retinaculum, possible tibial tuberosity transfer, or proximal tibial osteotomy

Patellofemoral Syndrome (Chondromalacia Patellae)

- syndrome of anterior knee pain associated with idiopathic articular changes of patella

Risk Factors

- malalignment causing patellar maltracking (Q angle $\geq 20^\circ$, genu valgus)
- post-trauma
- deformity of patella or femoral groove
- recurrent patellar dislocation, ligamentous laxity
- excessive knee strain (athletes)

Mechanism

- softening, erosion, and fragmentation of articular cartilage, predominantly medial aspect of patella
- commonly seen in active young females

Clinical Features

- deep, aching anterior knee pain
 - exacerbated by prolonged sitting (theatre sign), strenuous athletic activities, stair climbing, squatting, or kneeling
- insidious onset and vague in nature
- sensation of instability, pseudolocking
- pain with extension against resistance through terminal 30-40°
- pain with compression of patella with knee ROM or resisted knee extension
- swelling rare, minimal if present
- palpable crepitus

Investigations

- X-ray: AP, lateral, skyline – may find chondrosis, lateral patellar tilt, patella alta/baja, or shallow sulcus
- CT-scan
- MRI – best to assess articular cartilage

Figure 43. Q-angle

The angle between a vertical line through the patella and tibial tuberosity and a line from the ASIS to the middle patella; the larger the angle, the greater the amount of lateral force on the knee (normal $< 20^\circ$)

J-sign: associated with patella alta; increased lateral translation in extension which pops into the patellofemoral groove as the patella engages the trochlea early in flexion

Pain with firm compression of patella into medial femoral groove is pathognomonic of patellofemoral syndrome

Treatment

- non-operative
 - continue non-impact activities; rest and rehabilitation
 - NSAIDs
 - physiotherapy: vastus medialis and core strengthening
- operative
 - indication: failed non-operative treatment
 - tibial tubercle elevation
 - arthroscopic shaving/debridement
 - lateral release of retinaculum

Tibia

Tibial Plateau Fracture

Mechanism

- varus/valgus load ± axial loading (e.g. fall from height)
- femoral condyles driven into proximal tibia
- can result from minor trauma in those with osteoporosis

Clinical Features

- frequency: lateral > bicondylar > medial
- medial fractures require higher energy – often have concomitant vascular injuries
- knee effusion
- inability to bear weight
- swelling
- associated with compartment syndrome, ACL injury, and meniscal tears
- Schatzker classification

Investigations

- X-ray: AP, lateral, oblique
- CT: pre-operative planning, identify articular depression and comminution
- ABI if any differences in pulses between extremities

Treatment**Approach #1 (based on amount of depression seen on x-ray)**

Non-operative indication (if depression on x-ray is <3 mm): straight leg immobilization x 4-6 wk with progressive ROM weight bearing
Operative indication (if depression is >3 mm): ORIF often requiring bone grafting to elevate depressed fragment

Approach #2 (based on varus/valgus instability)

Non-operative indication (if minimal varus/valgus instability [$<15^\circ$]): straight leg immobilization x 4-6 wk with progressive ROM weight bearing
Operative indication (if significant varus/valgus instability [$>15^\circ$]): ORIF often requiring bone grafting to elevate depressed fragment

Specific Complications (see *General Fracture Complications, OR6*)

- ligamentous injuries
- meniscal lesions
- AVN
- infection
- OA

Tibial Shaft Fracture

- most common long bone fracture and open fracture

Mechanism

- low energy pattern: torsional injury
- high energy: including MVC, falls, sporting injuries

Clinical Features

- pain, inability to weight bear
- open vs. closed
- neurovascular compromise

Investigations

- X-ray: AP, lateral
 - full length, plus knee and ankle

**Schatzker Classification**

Type	Description
I	Involvement of lateral plateau split fracture
II	Lateral split-depressed fracture
III	Involvement of lateral plateau: pure depression fracture
IV	Medial plateau fracture
V	Bicondylar plateau fracture
VI	Bicondylar with metaphyseal/diaphyseal involvement

Figure 44. Tibial shaft fracture treated with IM nail and screws

Treatment

- non-operative
 - indication: closed and minimally displaced or adequate closed reduction
 - ♦ long leg cast x 8-12 wk, functional brace after
- operative
 - indication: displaced or open
 - ♦ if displaced and closed: ORIF with IM nail, plate and screws, or external fixator
 - ♦ if open: antibiotics, I&D, external fixation or IM nail, and vascularized coverage of soft tissue defects

Specific Complications (see *General Fracture Complications, OR6*)

- high incidence of neurovascular injury and compartment syndrome
- poor soft tissue coverage (critical to outcome)

Tibial shaft fractures have high incidence of compartment syndrome and are often associated with soft tissue injuries

Ankle

Evaluation of Ankle and Foot Complaints

Special Tests

- anterior drawer: examiner attempts to displace the foot anteriorly against a fixed tibia
- talar tilt: foot is stressed in inversion and angle of talar rotation is evaluated by X-ray

X-Ray

- AP, lateral
- mortise view: ankle at 15° of internal rotation
 - gives true view of ankle joint
 - joint space should be symmetric with no talar tilt
- Ottawa Ankle Rules should guide X-ray use (see *Emergency Medicine, ER17*); nearly 100% sensitivity
- ± CT to better characterize fractures

**Ottawa Ankle Rules** (see *Emergency Medicine, ER17*)

X-rays are only required if:
Pain in the malleolar zone AND bony tenderness over the distal 6 cm of the posterior aspect of the tibia or tip of the medial or lateral malleolus OR inability to weight bear both immediately after injury and in the ER

Ankle Fracture

Mechanism

- pattern of fracture depends on the position of the ankle when trauma occurs
- generally involves
 - ipsilateral ligamentous tears or transverse bony avulsion
 - contralateral shear fractures (oblique or spiral)
- classification systems
 - Danis-Weber
 - Lauge-Hansen: based on foot's position and motion relative to leg

Treatment

- non-operative
 - indication: non-displaced, no history of dislocation
 - below knee cast, NWB
- operative
 - indications
 - ♦ any fracture-dislocation: restore vascularity, minimize articular injury, reduce pain and skin pressure
 - ♦ most of type B, and all of type C
 - ♦ trimalleolar (medial, posterior, lateral) fractures
 - ♦ talar tilt >10°
 - ♦ medial clear space on X-ray greater than superior clear space
 - ♦ open fracture/open joint injury
 - ORIF

Complications

- high incidence of post-traumatic arthritis

Figure 45. Ring principle of the ankle and Danis-Weber classification

Ankle Ligamentous Injuries

- see Figure 46 for ankle ligaments

Medial Ligament Complex (deltoid ligament)

- eversion injury
- usually avulses medial or posterior malleolus and strains syndesmosis

Lateral Ligament Complex (Anterior Talofibular, Calcaneofibular, Posterior Talofibular)

- inversion injury, >90% of all ankle sprains
- ATF most commonly and severely injured if ankle is plantarflexed
- swelling and tenderness anterior to lateral malleolus
- ++ ecchymosis
- positive ankle anterior drawer
- may have significant medial talar tilt on inversion stress X-ray

Treatment

- non-operative
 - microscopic tear (Grade I)
 - ♦ rest, ice, compression, elevation
 - macroscopic tear (Grade II)
 - ♦ strap ankle in dorsiflexion and eversion x 4-6 wk
 - ♦ physiotherapy: strengthening and proprioceptive retraining
- complete tear (Grade III)
 - ♦ below knee walking cast x 4-6 wk
 - ♦ physiotherapy: strengthening and proprioceptive retraining
 - ♦ surgical intervention may be required if chronic symptomatic instability develops

Danis-Weber Classification

- based on level of fibular fracture relative to syndesmosis

Type A (infra-syndesmotiC)

- pure inversion injury
- avulsion of lateral malleolus below plafond or torn calcaneofibular ligament
- ± shear fracture of medial malleolus

Type B (trans-syndesmotiC)

- external rotation and eversion (most common)
- ± avulsion of medial malleolus or rupture of deltoid ligament
- spiral fracture of lateral malleolus starting at plafond

Type C (supra-syndesmotiC)

- pure external rotation
- avulsion of medial malleolus or torn deltoid ligament
- ± posterior malleolus avulsion with posterior tibio-fibular ligament
- fibular fracture is above plafond (called Maisonneuve fracture if at proximal fibula)
- frequently tears syndesmosis

With a history of significant trauma from axial loading of lower limb, always consider spinal injuries, femoral neck, tibial plateau, and talar/calcaneal fractures

Foot

Talar Fracture

Mechanism

- axial loading or hyperdorsiflexion (MVC, fall from height)
- 60% of talus covered by articular cartilage
- talar neck is most common fracture of talus (50%)
- tenuous blood supply runs distal to proximal along talar neck
 - high risk of AVN with displaced fractures

Investigations

- X-ray: AP, lateral, Canale view
- CT to better characterize fracture
- MRI can clearly define extent of AVN

Treatment

- non-operative
 - indication: non-displaced
 - NWB, below-knee cast x 6 wk
- operative
 - indication: displaced
 - ORIF (high rate of nonunion, AVN)
 - neck fracture: ORIF

Calcaneal Fracture

- most common tarsal fracture

Mechanism

- high energy, axial loading: fall from height onto heels
- 10% of fractures associated with compression fractures of thoracic or lumbar spine (rule out spine injury)
- 75% are intra-articular and 10% are bilateral

Clinical Features

- marked swelling, bruising on heel/sole
- wider, shortened, flatter heel when viewed from behind
- varus heel

Legend

- PTF: Posterior talofibular
- CF: Calcaneofibular
- ATF: Anterior talofibular
- PTT: Posterior tibiotalar
- TC: Tibiocalcaneal
- ATT: Anterior tibiotalar
- TN: Tibionavicular

Figure 46. Ankle ligament complexes

Investigations

- X-rays: AP, lateral, oblique foot (mandatory views); can also assess with Broden view, Harris view, or AP ankle.
- loss of Bohler's angle
- CT: gold-standard, assess intra-articular extension

Treatment

- closed vs. open reduction is controversial
- NWB cast x 3 mo with early ROM and strengthening

**Calcaneal Fracture Treatment Principles**

- Avoid wound complications (10-25%)
- Restore articular congruity
- Restore normal calcaneal width and height
- Maximum functional recovery may take longer than 12 mo

Achilles Tendonitis**Mechanism**

- chronic inflammation from activity or poor-fitting footwear
- may also develop heel bumps (retrocalcaneobursitis or Haglund deformity)

Clinical Features

- pain, stiffness, and crepitus with ROM
- thickened tendon, palpable bump

Investigations

- X-ray: lateral, evaluate bone spur and calcification; U/S, MRI (to assess degenerative change)

Treatment

- non-operative
 - rest, NSAIDs, shoe wear modification (orthotics, open back shoes)
 - heel sleeves and pads are mainstay of non-operative treatment
 - gentle gastrocnemius-soleus stretching, eccentric training with physical therapy, deep tissue calf massage
 - shockwave therapy in chronic tendonitis
 - DO NOT inject steroids (risk of tendon rupture)

Haglund Deformity: an enlargement of the posterior-superior tuberosity of the calcaneus

Achilles Tendon Rupture**Mechanism**

- loading activity, stop-and-go sports (e.g. squash, tennis, basketball)
- secondary to chronic tendonitis, steroid injection

Clinical Features

- audible pop, sudden pain with push-off movement
- pain or inability to plantarflex
- palpable gap
- apprehensive toe off when walking
- weak plantarflexion strength
- Thompson test: with patient prone, squeeze calf, normal response is plantar flexion
 - no passive plantarflexion is positive test = ruptured tendon

Investigations

- X-ray (to rule out other pathology), U/S or MRI (for partial vs. complete ruptures)

Treatment

- non-operative
 - indication: low athletic demand or elderly
 - cast foot in plantar flexion (to relax tendon) x 8-12 wk
- operative
 - indication: high athletic demand
 - surgical repair, then cast as above x 6-8 wk

The most common site of Achilles tendon rupture is 2-6 cm from its insertion where the blood supply is the poorest

**Complications of Achilles Tendon Rupture**

- Infection
- Sural nerve injury
- Re-rupture: surgical repair decreases likelihood of re-rupture compared to non-operative management

Plantar Fasciitis (Heel Spur Syndrome)**Definition**

- inflammation of plantar aponeurosis at calcaneal origin
- common in athletes (especially runners, dancers)
- also associated with obesity, DM, seronegative and seropositive arthritis

Mechanism

- repetitive strain injury causing microtears and inflammation of plantar fascia

Figure 47. X-ray of bony heel spur

Clinical Features

- insidious onset of heel pain, pain when getting out of bed, and stiffness
- intense pain when walking from rest that subsides as patient continues to walk, worse at end of day with prolonged standing
- swelling, tenderness over sole
- greatest at medial calcaneal tubercle and 1-2 cm distal along plantar fascia
- pain with toe dorsiflexion (stretches fascia)

Investigations

- plain radiographs to rule out fractures
- often see bony exostoses (heel spurs) at insertion of fascia into medial calcaneal tubercle
- spur is secondary to inflammation, not the cause of pain

Treatment

- non-operative
 - pain control and stretching programs are first-line
 - rest, ice, NSAIDs, steroid injection
 - physiotherapy: Achilles tendon and plantar fascia stretching, extracorporeal shockwave therapy
 - orthotics with heel cup – to counteract pronation and disperse heel strike forces
- operative
 - indication: failed non-operative treatment
 - endoscopic surgical release of fascia
 - spur removal is not required

Bunions (Hallux Valgus)

Definition

- bony deformity characterized by medial displacement of first metatarsal and lateral deviation of hallux

Mechanism

- valgus alignment on 1st MTP (hallux valgus) causes eccentric pull of extensor and intrinsic muscles
- many associated deformities in foot from altered mechanics
- reactive exostosis forms with thickening of the skin, creating a bunion
- most often associated with poor-fitting footwear (high heel and narrow toe box)
- can be hereditary (70% have family history)
- 10x more frequent in women

Clinical Features

- painful bursa over medial eminence of 1st MT head
- pronation (rotation inward) of great toe
- numbness over medial aspect of great toe

Investigations

- X-ray: standing AP/lateral/sesamoid view, NWB oblique

Treatment

- indications: painful corn or bunion, overriding 2nd toe
- non-operative (first-line)
 - properly fitted shoes (low heel) and toe spacer
- operative: goal is to restore normal anatomy, not cosmetic reasons alone
 - osteotomy with realignment of 1st MTP joint (Chevron Procedure)
 - arthrodesis

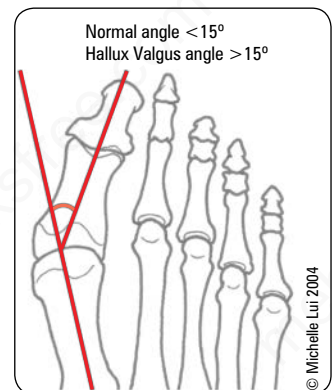

Figure 48. Hallux valgus

Metatarsal Fracture

- as with the hand, 1st, 4th, 5th MT are relatively mobile, while the 2nd and 3rd are fixed
- use Ottawa Foot Rules to determine need for x-ray

Table 22. Types of Metatarsal Fractures

Fracture Type	Mechanism	Clinical	Treatment
Avulsion of Base of 5th MT	Sudden inversion followed by contraction of peroneus brevis	Tender base of 5th MT	Requires ORIF if displaced
Midshaft 5th MT (Jones Fracture)	Stress injury	Painful shaft of 5th MT	*NWB BK cast x 6 wk ORIF if athlete
Shaft 2nd, 3rd MT (March Fracture)	Stress injury	Painful shaft of 2nd or 3rd MT	Symptomatic
1st MT	Trauma	Painful 1st MT	ORIF if displaced otherwise *NWB BK cast x 3 wk then walking cast x 2 wk
Tarso-MT Fracture – Dislocation (Lisfranc Fracture)	Fall onto plantar flexed foot or direct crush injury	Shortened forefoot prominent base	ORIF

*NWB BK = Non weight bearing, below knee

Ottawa Ankle and Foot Rules
 (see [Emergency Medicine, ER17](#))
 X-rays only required if:
 Pain in the midfoot zone AND bony tenderness over the navicular or base of the fifth metatarsal OR inability to weight bear both immediately after injury and in the ER

Pediatric Orthopedics

Fractures in Children

- type of fracture
 - thicker, more active periosteum results in pediatric-specific fractures: greenstick (one cortex), torus (i.e. 'buckle', impacted cortex) and plastic (bowing)
 - distal radius fracture most common in children (phalanges second), the majority are treated with closed reduction and casting
 - adults fracture through both cortices
- epiphyseal growth plate
 - weaker part of bone, susceptible to fractures
 - plate often mistaken for fracture on x-ray and vice versa (X-ray opposite limb for comparison), especially in elbow
 - tensile strength of bone < ligaments in children, therefore clinician must be confident that fracture and/or growth plate injury have been ruled out before diagnosing a sprain
 - intra-articular fractures have worse consequences in children because they usually involve the growth plate
- anatomic reduction
 - gold standard with adults
 - may cause limb length discrepancy in children (overgrowth)
 - accept greater angular deformity in children (remodelling minimizes deformity)
- time to heal
 - shorter in children
- always be aware of the possibility of child abuse
 - make sure stated mechanism compatible with injury
 - high index of suspicion with fractures in non-ambulating children (<1 yr); look for other signs, including X-ray evidence of healing fractures at different sites and different stages of healing
 - common suspicious fractures in children: metaphyseal corner fracture (hallmark of non-accidental trauma), femur fracture < 1 yo, humeral shaft < 3 yo, sternal fractures, posterior rib fractures, spinous process fractures

Figure 49. Greenstick (left) and torus (right) fractures

Greenstick fractures are easy to reduce but can redisplace while in cast due to intact periosteum

Stress Fractures

Mechanism

- insufficiency fracture
 - stress applied to a weak or structurally deficient bone
- fatigue fracture
 - repetitive, excessive force applied to normal bone
- most common in adolescent athletes
- tibia is most common site

Diagnosis

- localized pain and tenderness over the involved bone
- plain films may not show fracture for 2 wk
- bone scan positive in 12-15 d

Treatment

- rest from strenuous activities to allow remodelling (can take several months)

Epiphyseal Injury

Table 23. Salter-Harris Classification of Epiphyseal Injury

SALT(E)R-Harris Type	Description	Treatment
I (Straight through; Stable)	Transverse through growth plate	Closed reduction and cast immobilization (except SCFE – ORIF); heals well, 95% do not affect growth
II (Above)	Through metaphysis and along growth plate	Closed reduction and cast if anatomic; otherwise ORIF
III (Low)*	Through epiphysis to plate and along growth plate	Anatomic reduction by ORIF to prevent growth arrest, avoid fixation across growth plate
IV (Through and through)*	Through epiphysis and metaphysis	Closed reduction and cast if anatomic; otherwise ORIF
V (Ram)*	Crush injury of growth plate	High incidence of growth arrest; no specific treatment

* Types III – IV are more likely to cause growth arrest and progressive deformity

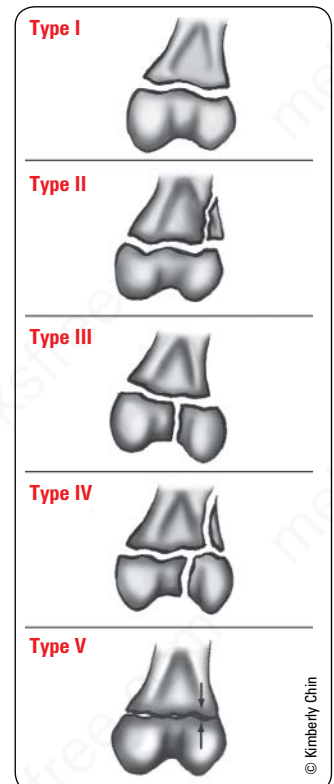

Figure 50. Salter-Harris classification

Slipped Capital Femoral Epiphysis

Definition

- type I Salter-Harris epiphyseal injury at proximal hip
- most common adolescent hip disorder, peak incidence at pubertal growth spurt
- risk factors: male, obese (#1 factor), hypothyroid (risk of bilateral involvement)

Etiology

- multifactorial
 - genetic: autosomal dominant, black children at highest risk
 - cartilaginous physis hypertrophies too rapidly under growth hormone effects
 - sex hormone secretion, which stabilizes physis, has not yet begun
 - overweight: mechanical stress
 - trauma: causes acute slip

Clinical Features

- acute: sudden, severe pain with limp
- chronic (typically): groin and anterior thigh pain, may present with knee pain
 - positive Trendelenburg sign on affected side, due to weakened gluteal muscles
- tender over joint capsule
- restricted internal rotation, abduction, flexion
 - Whitman's sign: obligatory external rotation during passive flexion of hip
- Loder classification: stable vs. unstable (provides prognostic information)
 - unstable means patient cannot ambulate even with crutches

Investigations

- X-ray: AP, frog-leg, lateral radiographs both hips
 - posterior and medial slip of epiphysis
 - disruption of Klein's line
 - AP view may be normal or show widened/lucent growth plate compared with opposite side

Treatment

- operative
 - mild/moderate slip: stabilize physis with pins in current position
 - severe slip: ORIF or pin physis without reduction and osteotomy after epiphyseal fusion

Complications

- AVN (roughly half of unstable hips), chondrolysis (loss of articular cartilage, resulting in narrowing of joint space), pin penetration, premature OA, loss of ROM

Bilateral involvement occurs in about 25%

Klein's Line

On AP view, line drawn along supero-lateral border of femoral neck should cross at least a portion of the femoral epiphysis. If it does not, suspect SCFE

Developmental Dysplasia of the Hip

Definition

- abnormal development of hip, resulting in dysplasia and subluxation/dislocation of hip
- most common orthopedic disorder in newborns

Etiology

- due to ligamentous laxity, muscular underdevelopment, and abnormal shallow slope of acetabular roof
- spectrum of conditions
 - dislocated femoral head completely out of acetabulum
 - dislocatable head in socket
 - head subluxates out of joint when provoked
 - dysplastic acetabulum, more shallow and more vertical than normal
- if painful, suspect septic dislocation (normally painless)

Physical Exam

- diagnosis is clinical
 - limited abduction of the flexed hip (<60°)
 - affected leg shortening results in asymmetry in skin folds and gluteal muscles, wide perineum
 - Barlow's test (checks if hips are dislocatable (Figure 51))
 - ♦ flex hips and knees to 90° and grasp thigh
 - ♦ fully adduct hips, push posteriorly to try to dislocate hips
 - Ortolani's test (checks if hips are dislocated (Figure 51))
 - ♦ initial position as above but try to reduce hip with fingertips during abduction
 - ♦ positive test: palpable clunk is felt (not heard) if hip is reduced
 - Galeazzi's sign
 - ♦ knees at unequal heights when hips and knees flexed
 - ♦ dislocated hip on side of lower knee
 - ♦ difficult test if child <1 yr
 - ♦ Trendelenburg test and gait useful if older (>2 yr)

Figure 51. Barlow's test and Ortolani's test

Investigations

- U/S in first few months to view cartilage (bone is not calcified in newborns until 4-6 mo)
- follow-up radiograph after 3 mo
- X-ray signs (at 4-6 mo): false acetabulum, acetabular index $>25^\circ$, broken Shenton's line, femoral neck above Hilgenreiner's line, ossification centre outside of inner lower quadrant (quadrants formed by intersection of Hilgenreiner's and Perkin's lines)

Treatment

- 0-6 mo: reduce hip using Pavlik harness to maintain abduction and flexion
- 6-18 mo: reduction under GA, hip spica cast x 2-3 mo (if Pavlik harness fails)
- >18 mo: open reduction; pelvic and/or femoral osteotomy

Complications

- redislocation, inadequate reduction, stiffness
- AVN of femoral head

5 Fs that Predispose to Developmental Dysplasia of the Hip

- Family history
- Female
- Frank breech
- First born
- LeFt hip

Legg-Calvé-Perthes Disease (Coxa Plana)

Definition

- idiopathic AVN of femoral head, presents at 4-8 yr of age
- 12% bilateral, M>F = 5:1, 1/1,200
- associations
 - family history
 - low birth weight
 - abnormal pregnancy/delivery
 - ADHD in 33% of cases, delayed bone age in 89%
 - second-hand smoke exposure
 - Asian, Inuit, Central European
- key features
 - AVN of proximal femoral epiphysis, abnormal growth of the physis, and eventual remodelling of regenerated bone

Clinical Features

- child with antalgic or Trendelenburg gait \pm pain
- intermittent knee, hip, groin, or thigh pain
- flexion contracture (stiff hip): decreased internal rotation and abduction of hip
- limb length discrepancy (late)

Investigations

- X-ray: AP pelvis, frog leg laterals
- may be negative early (if high index of suspicion, move to bone scan or MRI)
- eventually, characteristic collapse of femoral head (diagnostic)

Treatment

- goal is to preserve ROM and keep femoral head contained in acetabulum
- non-operative
 - physiotherapy: ROM exercises
 - brace in flexion and abduction x 2-3 yr (controversial)
- operative
 - femoral or pelvic osteotomy (>8 yr of age or severe)
 - ♦ prognosis better in males, <6 yr, $<50\%$ of femoral head involved, abduction $>30^\circ$
- 60% of involved hips do not require operative intervention
- natural history is early onset OA and decreased ROM

Osgood-Schlatter Disease

Definition

- inflammation of patellar ligament at insertion point on tibial tuberosity
- M>F
- age of onset: boys 12-15 yr; girls 8-12 yr

Mechanism

- repetitive tensile stress on insertion of patellar tendon over the tibial tuberosity causes minor avulsion at the site and subsequent inflammatory reaction (tibial tubercle apophysitis)

Clinical Features

- tender lump over tibial tuberosity
- pain on resisted leg extension
- anterior knee pain exacerbated by jumping or kneeling, relieved by rest

Investigations

- X-ray lateral knee: fragmentation of the tibial tubercle, \pm ossicles in patellar tendon

Figure 52. Pelvic x-ray and reference lines and angles for assessment of DDH

- Triradiate Cartilage**
y-shaped epiphyseal plate at junction of ilium, ischium and pubis
- Hilgenreiner's Line**
Line running between triradiate cartilages
- Perkin's Line**
Line through lateral margin of acetabulum, perpendicular to Hilgenreiner's Line
- Shenton's Line**
Arced line along inferior border of femoral neck and superior margin of obturator foramen
- Acetabular Index**
Angle between Hilgenreiner's Line and line from triradiate cartilage to point on lateral margin of acetabulum

Most common in adolescent athletes, especially jumping/sprinting sports

Children diagnosed with coxa plana <6 yr of age have improved prognosis

Treatment

- benign, self-limited condition, does not resolve until growth halts
- non-operative (majority)
 - may restrict activities such as basketball or cycling
 - NSAIDs, rest, flexibility, isometric strengthening exercises
 - casting if symptoms do not resolve with conservative management
- operative: ossicle excision in refractory cases (patient is skeletally mature with persistent symptoms)

Congenital Talipes Equinovarus (Club Foot)

Definition

- congenital foot deformity
- muscle contractures resulting in CAVE deformity
- bony deformity: talar neck medial and plantar deviated; varus calcaneus and rotated medially around talus; navicular and cuboid medially displaced
- 1-2/1,000 newborns, 50% bilateral, occurrence M>F, severity F>M

Etiology

- intrinsic causes (neurologic, muscular, or connective tissue diseases) vs. extrinsic (intrauterine growth restriction); may be idiopathic, neurogenic, or syndrome-associated
- fixed deformity

Physical Exam

- examine hips for associated DDH
- examine knees for deformity
- examine back for dysraphism (unfused vertebral bodies)

Treatment

- largely non-operative via Ponseti Technique (serial manipulation and casting)
 - correct deformities in CAVE order
 - ♦ change strapping/cast q1-2wk
 - ♦ surgical release in refractory case (rare)
 - delayed until 3-4 mo of age
- 3 yr recurrence rate = 5-10%
- mild recurrence common; affected foot is permanently smaller/stiffer than normal foot with calf muscle atrophy

Figure 53. Club Foot - depicting the gross and bony deformity

CAVE deformity

- midfoot Cavus
- forefoot Adductus
- hindfoot Varus
- hindfoot Equinus

Scoliosis

Definition

- lateral curvature of spine with vertebral rotation
- age: 10-14 yr
- more frequent and more severe in females

Etiology

- idiopathic: most common (90%)
- congenital: vertebrae fail to form or segment
- neuromuscular: UMN or LMN lesion, myopathy
- postural: leg length discrepancy, muscle spasm
- other: osteochondrodystrophies, neoplastic, traumatic

Clinical Features

- ± back pain
- primary curve where several vertebrae affected
- secondary curves above and below fixed 1° curve to try and maintain normal position of head and pelvis
- asymmetric shoulder height when bent forward
- Adam's test: rib hump when bent forward
- prominent scapulae, creased flank, asymmetric pelvis
- associated posterior midline skin lesions in neuromuscular scolioses
 - café-au-lait spots, dimples, neurofibromas
 - axillary freckling, hemangiomas, hair patches
- associated pes cavus or leg atrophy
- apparent leg length discrepancy

Investigations

- X-ray: 3-foot standing, AP, lateral
 - measure curvature: Cobb angle
 - may have associated kyphosis

Figure 54. Cobb angle – used to monitor the progression of the scoliotic curve

Scoliosis screening is not recommended in Canada (Grieg A, et al. 2010; Health Canada, 1994)

In structural or fixed scoliosis, bending forwards makes the curve more obvious

Treatment

- based on Cobb angle
 - <25°: observe for changes with serial radiographs
 - >25° or progressive: bracing (many types) that halt/slow curve progression but do NOT reverse deformity
 - >45°, cosmetically unacceptable, or respiratory problems: surgical correction (spinal fusion)

Postural scoliosis can be corrected by correcting the underlying problem

Bone Tumours

- primary bone tumours are rare after 3rd decade
- metastases to bone are relatively common after 3rd decade

Clinical Features

- malignant (primary or metastasis): local pain and swelling (wk – mo), worse on exertion and at night, ± soft tissue mass
- benign: usually asymptomatic
- minor trauma often initiating event that calls attention to lesion

Table 24. Distinguishing Benign from Malignant Bone Lesions on X-Ray

Benign	Malignant
No periosteal reaction	Acute periosteal reaction <ul style="list-style-type: none"> Codman's triangle (Figure 55) "Onion skin" "Sunburst"
Thick endosteal reaction	Broad border between lesion and normal bone
Well developed bone formation	Varied bone formation
Intraosseous and even calcification	Extraosseous and irregular calcification

Adapted from: Buckholtz RW, Heckman JD. Rockwood and Green's Fractures in Adults. Volume 1. Philadelphia: Lippincott Williams & Wilkins, 2001. p558

Diagnosis

- malignancy is suggested by rapid growth, warmth, tenderness, lack of sharp definition
- staging should include
 - blood work including liver enzymes
 - CT chest
 - bone scan
 - bone biopsy
 - should be referred to specialized centre prior to biopsy
 - classified into benign, benign aggressive, and malignant
 - MRI of affected bone

Benign Active Bone Tumours

BONE-FORMING TUMOURS

Osteoid Osteoma

- bone tumour arising from osteoblasts
- peak incidence in 2nd and 3rd decades, M:F = 2:1
- proximal femur and tibia diaphysis most common locations
- not known to metastasize
- radiographic findings: small, round radiolucent nidus (<1.5 cm) surrounded by dense sclerotic bone ("bull's-eye")
- symptoms: produces severe intermittent pain from prostaglandin secretion and COX1/2 expression, mostly at night (diurnal prostaglandin production), thus is characteristically relieved by NSAIDs
- treatment: NSAIDs for night pain; surgical resection of nidus

FIBROUS LESIONS

Fibrous Cortical Defect

- or non-ossifying fibroma; fibrous bone lesion
- most common benign bone tumour in children, typically asymptomatic and an incidental finding
- occur in as many as 35% of children, peak incidence between 2-25 yr old, higher prevalence in males
- femur and proximal tibia most common locations, 50% of patients have multiple defects that are usually bilateral, symmetrical
- radiographic findings: diagnostic, metaphyseal eccentric 'bubbly' lytic lesion near physis; thin, smooth/lobulated, well-defined sclerotic margin
- treatment: most lesions resolve spontaneously

Red Flags

- Persistent skeletal pain
- Localized tenderness
- Spontaneous fracture
- Enlarging mass/soft tissue swelling

X-ray Findings

- lytic, lucent, sclerotic bone
- involvement of cortex, medulla, soft tissue
- radiolucent, radiopaque, or calcified matrix
- periosteal reaction
- permeative margins
- pathological fracture
- soft tissue swelling

Figure 55. Codman's triangle – a radiographic finding in malignancy, where the partially ossified periosteum is lifted off the cortex by neoplastic tissue

Osteochondroma

- cartilage capped bony tumour
- 2nd and 3rd decades, M:F = 1.8:1
- most common of all benign bone tumours – 45%
- 2 types: sessile (broad based and increased risk of malignant degeneration) vs. pedunculated (narrow stalk)
- metaphysis of long bone near tendon attachment sites (usually distal femur, proximal tibia, or proximal humerus)
- radiographic findings: cartilage-capped bony spur on surface of bone (“mushroom” on x-ray)
- may be multiple (hereditary, autosomal dominant form) – higher risk of malignant change
- generally very slow growing and asymptomatic unless impinging on neurovascular structure (‘painless mass’)
 - growth usually ceases when skeletal maturity is reached
- malignant degeneration occurs in 1-2% (becomes painful or rapidly grows)
- treatment: typically observation; surgical excision if symptomatic

Enchondroma

- hyaline cartilage tumour; majority asymptomatic, presenting as incidental finding or pathological fracture
- 2nd and 3rd decades
- 60% occur in the small tubular bones of the hand and foot; others in femur (20% - Figure 56), humerus, ribs
- benign cartilaginous growth, an abnormality of chondroblasts, develops in medullary cavity
 - single/multiple enlarged rarefied areas in tubular bones
 - lytic lesion with sharp margination and irregular central calcification (stippled/punctate/popcorn appearance)
- malignant degeneration to chondrosarcoma occurs in 1-2% (pain in absence of pathologic fracture is an important clue)
- not known to metastasize
- treatment: observation with serial x-rays; surgical curettage if symptomatic or lesion grows

CYSTIC LESIONS

Unicameral/Solitary Bone Cyst

- most common cystic lesion; serous fluid-filled lesion
- children and young adults, peak incidence during first 2 decades, M:F = 2:1
- proximal humerus and femur most common
- symptoms: asymptomatic, or local pain; complete pathological fracture (50% of presentations) or incidental detection
- radiographic findings: lytic translucent area on metaphyseal side of growth plate, cortex thinned/expanded; well-defined lesion
- treatment: aspiration followed by steroid injection; curettage ± bone graft indicated if re-fracture likely

Figure 56. T1MRI of femoral enchondroma

Benign Aggressive Bone Tumours

Giant Cell Tumours/Aneurysmal Bone Cyst/Osteoblastoma

- affects patients of skeletal maturity, peak 3rd decade
- osteoblastoma: found in the distal femur, proximal tibia, distal radius, sacrum, tarsal bones, spine
- giant cell tumour: pulmonary metastases in 3%
- aneurysmal bone cysts (Figure 57): either solid with fibrous/granular tissue, or blood-filled
- radiographic findings
 - giant cell tumour: eccentric lytic lesions in epiphyses adjacent to subchondral bone; may break through cortex; T2 MRI enhances fluid within lesion (hyper-intense signal)
 - aneurysmal bone cyst: expanded with honeycomb shape
 - osteoblastoma: often nonspecific; calcified central nidus (>2 cm) with radiolucent halo and sclerosis
- symptoms: local tenderness and swelling, pain may be progressive (giant cell tumours), ± symptoms of nerve root compression (osteoblastoma)
- 15% recur within 2 yr of surgery

Treatment

- intralesional curettage + bone graft or cement
- wide local excision of expendable bones

Figure 57. X-ray of aneurysmal bone cyst
Note the aggressive destruction of bone

Malignant Bone Tumours

Table 25. Most Common Malignant Tumour Types for Age

Benign	Malignant
No periosteal reaction	Acute periosteal reaction <ul style="list-style-type: none"> • Codman's triangle • "Onion skin" • "Sunburst"
Thick endosteal reaction	Broad border between lesion and normal bone
Well developed bone formation	Varied bone formation
Intraosseous and even calcification	Extraosseous and irregular calcification

Adapted from: Buckholtz RW, Heckman JD. Rockwood and Green's Fractures in Adults. Volume 1. Philadelphia: Lippincott Williams & Wilkins, 2001. p558

Osteosarcoma

- malignant bone tumour
- most frequently diagnosed in 2nd decade of life (60%), 2nd most common primary malignancy in adults
- history of Paget's disease (elderly patients), previous radiation treatment
- predilection for sites of rapid growth: distal femur (45% - **Figure 58**), proximal tibia (20%), and proximal humerus (15%)
 - invasive, variable histology; frequent metastases without treatment (lung most common)
- painful symptoms: progressive pain, night pain, poorly defined swelling, decreased ROM
- radiographic findings
 - characteristic periosteal reaction: Codman's triangle (**Figure 55**) or "sunburst" spicule formation (tumour extension into periosteum)
 - destructive lesion in metaphysis may cross epiphyseal plate
- management: complete resection (limb salvage, rarely amputation), neo-adjuvant chemo; bone scan – rule out skeletal metastases, CT chest – rule out pulmonary metastases
- prognosis: 70% survival (high-grade); 90% survival (low-grade)

Chondrosarcoma

- malignant chondrogenic tumour
- primary (2/3 cases)
 - previous normal bone, patient >40 yr; expands into cortex to cause pain, pathological fracture
- secondary (1/3 cases)
 - malignant degeneration of pre-existing cartilage tumour such as enchondroma or osteochondroma
 - age range 25-45 yr, better prognosis than primary chondrosarcoma
- symptoms: progressive pain, uncommonly palpable mass
- radiographic findings: in medullary cavity, irregular "popcorn" calcification (**Figure 59**)
- treatment: unresponsive to chemotherapy, treat with aggressive surgical resection + reconstruction; regular follow-up X-rays of resection site and chest
- prognosis: 10 yr survival 90% for low-grade, 20-40% for high-grade

Ewing's Sarcoma

- malignant, small round cell sarcoma
- most occur between 5-25 yr old
- florid periosteal reaction in metaphyses of long bone with diaphyseal extension
- metastases frequent without treatment
- signs/symptoms: presents with pain, mild fever, erythema, and swelling; anemia, increased WBC, ESR, LDH (mimics an infection)
- radiographic findings: moth-eaten appearance with periosteal lamellated pattern ("onion-skinning")
- treatment: resection, chemotherapy, radiation
- prognosis – 70% survival, worst prognostic factor is distant metastases

Multiple Myeloma

- proliferation of neoplastic plasma cells
- most common primary malignant tumour of bone in adults (~43%)
- 90% occur in people >40 yr old, M:F = 2:1; twice as common in African-Americans
- signs/symptoms: localized bone pain (cardinal early symptom), compression/pathological fractures, renal failure, nephritis, high incidence of infections (e.g. pyelonephritis/pneumonia), systemic (weakness, weight loss, anorexia)
- labs: anemia, thrombocytopenia, increased ESR, hypercalcemia, increased Cr
- radiographic findings: multiple, "punched-out" well-demarcated lesions, no surrounding sclerosis, marked bone expansion
- diagnosis
 - serum/urine immunoelectrophoresis (monoclonal gammopathy)
 - CT-guided biopsy of lytic lesions at multiple bony sites

Figure 58. X-ray of osteosarcoma of distal femur

Figure 59. X-ray of femur chondrosarcoma

Signs of Hypercalcemia

"Bones, Stones, Moans, Groans, Psychiatric overtones"
 CNS: headache, confusion, irritability, blurred vision
 GI: N/V, abdominal pain, constipation, weight loss
 MSK: fatigue, weakness, unsteady gait, bone and joint pain
 GU: nocturia, polydipsia, polyuria, UTIs

- treatment: chemotherapy, bisphosphonates, radiation, surgery for symptomatic lesions or impending fractures – debulking, internal fixation
- prognosis: 5 yr survival 30%; 10 yr survival 11%
- see [Hematology, H49](#)

Bone Metastases

- most common cause of bone lesions in adults; typically age >40
- 2/3 from breast or prostate; also consider thyroid, lung, kidney
- usually osteolytic; prostate occasionally osteoblastic
- may present with mechanical pain and/or night pain, pathological fracture, hypercalcemia
- bone scan for MSK involvement, MRI for spinal involvement may be helpful
- treatment: pain control, bisphosphonates, stabilization of impending fractures if Mirel's Criteria >8 (ORIF, IM rod, bone cement)

Most Common Tumours Metastatic to Bone

BLT with a Koshier Pickle

- Breast
- Lung
- Thyroid
- Kidney
- Prostate

Table 26. Mirel's Criteria for Impending Fracture Risk and Prophylactic Internal Fixation

Variable	Number Assigned		
	1	2	3
Site	Upper arm	Lower extremity	Peritrochanteric
Pain	Mild	Moderate	Severe
Lesion	Blastic	Mixed	Lytic
Size	<1/3 bone diameter	1/3-2/3 diameter	>2/3 diameter

Common Medications

Table 27. Common Medications

Drug Name	Dosing Schedule	Indications	Comments
cefazolin (Ancef®)	1-2 g IV q8h	Prophylactically before orthopedic surgery	First generation cephalosporin; do not use with penicillin allergy
heparin	5000 IU SC q12h	To prevent venous thrombosis and pulmonary emboli	Monitor platelets, follow PTT which should rise 1.5-2x
LMWH dalteparin (Fragmin®) enoxaparin (Lovenox®) fondaparinux (Arixtra®)	5000 IU SC OD 30-40 mg SC bid 2.5 mg SC OD	DVT prophylaxis especially in hip and knee surgery	Fixed dose, no monitoring, improved bioavailability, increased bleeding rates
oral anticoagulants dabigatran (Pradaxa®) rivaroxaban (Xarelto®) apixaban	110 mg PO x1 then 220 mg PO OD 10 mg PO OD 2.5 mg PO bid	DVT prophylaxis especially TKA and THA	Predictable, no monitoring, oral administration; no antidote
midazolam (Versed®)	0.02-0.04 mg/kg IV	Conscious sedation for short procedures	Medication used during fracture reduction – monitor for respiratory depression
fentanyl (Sublimaze®)	0.5-3 µg/kg IV	Conscious sedation for short procedures	Short acting anesthetic used in conjunction with midazolam (Versed®)
triamcinolone (Aristocort®) – an injectable steroid	0.5-1 mL of 25 mg/mL	Suspension (injected into inflamed joint or bursa); amount varies by joint size	Potent anti-inflammatory effect; increased pain for 24 h, rarely causes fat necrosis and skin depigmentation
naproxen (Aleve®, Naprosyn®)	250-500 mg bid	Pain due to inflammation, arthritis, soft tissue injury	NSAID, may cause gastric erosion and bleeding
misoprostol (Cytotec®)	200 µg qid	Prophylaxis of HO after THA	Use with indomethacin
indomethacin (Indocid®)	25 mg PO tid	Prophylaxis of HO after THA	Use with misoprostol
ibuprofen (Advil®, Motrin®)	200-400 mg tid	Pain (including post-operative), inflammation (including arthritis)	NSAID, may cause gastric erosion and bleeding
propofol (Diprivan®)	1-2 mg/kg IV maintenance 0.5 mg/kg	Conscious sedation for short procedures	Short acting anesthetic often used in conjunction with fentanyl (Sublimaze®)

Figure 9. Anatomy of the neck

Anatomical Triangles of the Neck

Anterior triangle

- bounded by anterior border of SCM, midline of neck, and lower border of mandible
- divided into:
 - **submental triangle:** bounded by both anterior belly of digastric and hyoid bone
 - **digastric triangle:** bounded by anterior and posterior bellies of digastric and inferior border of mandible
 - **carotid triangle:** bounded by sternocleidomastoid, anterior belly of omohyoid, and posterior belly of digastric
 - ♦ contains: tail of parotid, submandibular gland, hypoglossal nerve, carotid bifurcation, and lymph nodes

Posterior triangle

- bounded by posterior border of sternocleidomastoid, anterior border of trapezius, and middle third of clavicle
- divided into:
 - **occipital triangle:** superior to posterior belly of the omohyoid
 - **subclavian triangle:** inferior to posterior belly of omohyoid
- contains: spinal accessory nerve and lymph nodes

Table 1. Lymphatic Drainage of Nodal Groups and Anatomical Triangles of Neck

Nodal Group/Level	Location	Drainage
1. Suboccipital (S)	Base of skull, posterior	Posterior scalp
2. Retroauricular (R)	Superficial to mastoid process	Scalp, temporal region, external auditory meatus, posterior pinna
3. Parotid-preauricular (P)	Anterior to ear	External auditory meatus, anterior pinna, soft tissue of frontal and temporal regions, root of nose, eyelids, palpebral conjunctiva
4. Submental (Level IA)	Anterior bellies (midline) of digastric muscles, tip of mandible, and hyoid bone	Floor of mouth, anterior tongue, anterior mandibular alveolar ridge, lower lip
5. Submandibular (Level IB)	Anterior belly of digastric muscle, stylohyoid muscle, body of mandible	Oral cavity, anterior nasal cavity, soft tissues of the mid-face, submandibular gland
6. Upper jugular (Levels IIA and IIB)	Skull base to inferior border of hyoid bone along SCM muscle	Oral cavity, nasal cavity, naso/oro/hypopharynx, larynx, parotid glands
7. Middle jugular (Level III)	Inferior border of hyoid bone to inferior border of cricoid cartilage along SCM muscle	Oral cavity, naso/oro/hypopharynx, larynx
8. Lower jugular* (Level IV)	Inferior border of cricoid cartilage to clavicle along SCM muscle	Hypopharynx, thyroid, cervical esophagus, larynx
9. Posterior triangle** (Levels VA and VB)	Posterior border of SCM, anterior border of trapezius, from skull base to clavicle	Nasopharynx and oropharynx, cutaneous structures of the posterior scalp and neck
10. Anterior compartment*** (Level VI)	Hyoid bone (midline) to suprasternal notch between the common carotid arteries	Thyroid gland, glottic and subglottic larynx, apex of piriform sinus, cervical esophagus

*Virchow node: left lower jugular (level IV) supraclavicular node

**Includes some supraclavicular nodes

***Includes pretracheal, precricoid, paratracheal, and perithyroidal nodes

Paired Parasympathetic Ganglia of the Head and Neck

- **Ciliary:** pupillary constriction
- **Pterygopalatine:** lacrimal gland, nasal mucosa
- **Submandibular:** submandibular, sublingual glands
- **Otic:** parotid gland

Function of Facial Nerve

"Ears, Tears, Face, Taste"

Ears: stapedius muscle

Tears: lacrimation (lacrimal gland) and salivation (parotid)

Face: muscles of facial expression

Taste: sensory anterior 2/3 of tongue (via chorda tympani)

- **Left-sided** enlargement of a supraclavicular node (Virchow's node) may indicate an abdominal malignancy
- **Right-sided** enlargement may indicate malignancy of the mediastinum, lungs, or esophagus
- **Occipital and/or posterior auricular node** enlargement may indicate rubella

4 Strap Muscles of the Neck

- Thyrohyoid
- Omohyoid
- Sternohyoid
- Sternothyroid

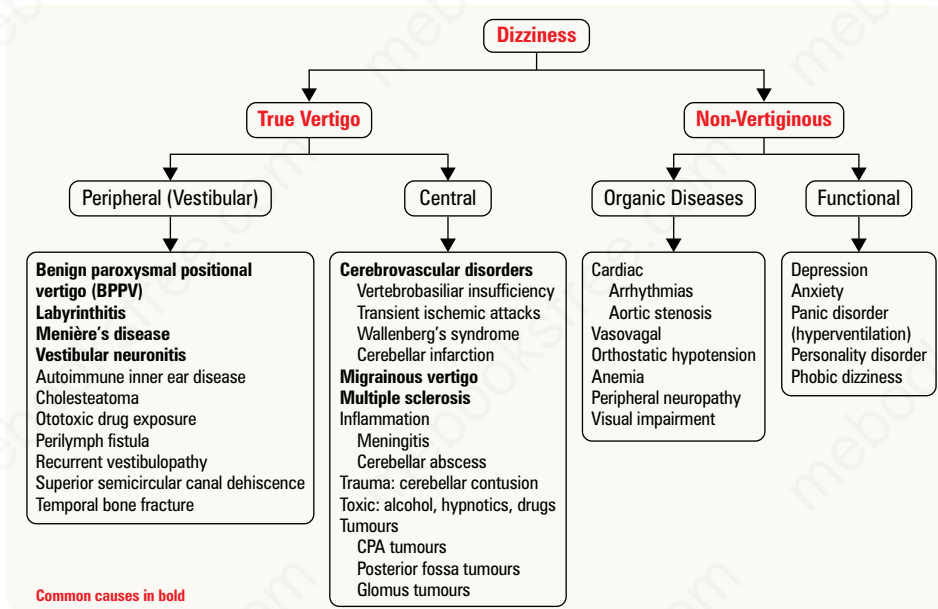

- STA – Superior thyroid artery
- CCA – Common carotid artery
- IVJ – Internal jugular vein
- ITA – Inferior thyroid artery
- RRLN – Right recurrent laryngeal nerve
- TC – Thyroid cartilage
- CC – Cricoid cartilage
- SPG – Superior parathyroid gland
- TG – Thyroid gland
- IPG – Inferior parathyroid gland
- VN (CN X) – Vagus nerve (CN X)
- LRLN – Left recurrent laryngeal nerve

*Thyroidea ima artery: present in 3% of population, arises from aortic arch or innominate artery

Figure 10. Anatomy of the thyroid gland

Differential Diagnoses of Common Presentations

Dizziness

True nystagmus and vertigo caused by a peripheral lesion will never last longer than a few weeks, due to compensation from the cerebellum (unless there is a history of cerebellar ischemia/stroke). Central lesions do not compensate, therefore nystagmus and vertigo will persist

5 "D's" of Vertebrobasilar Insufficiency
 Drop attacks
 Diplopia
 Dysarthria
 Dizziness
 Dysphagia

Figure 11. Differential diagnosis of dizziness

Otalgia

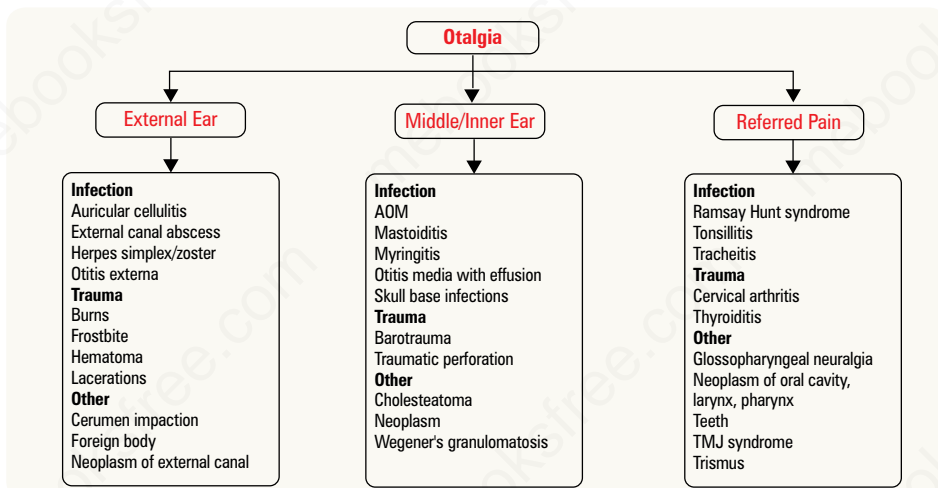

Figure 12. Differential diagnosis of otalgia

Hearing Loss

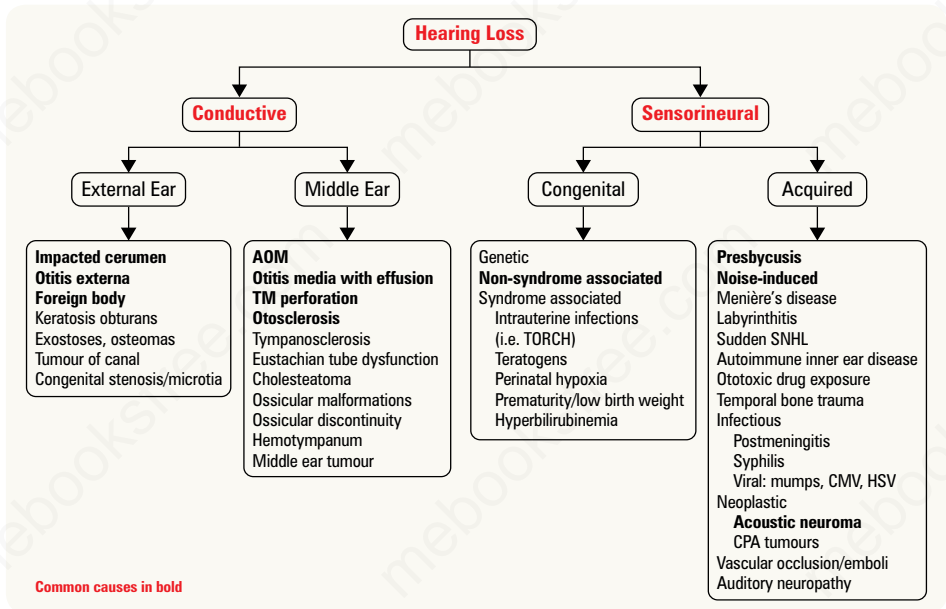

Figure 13. Differential diagnosis of hearing loss

Tinnitus

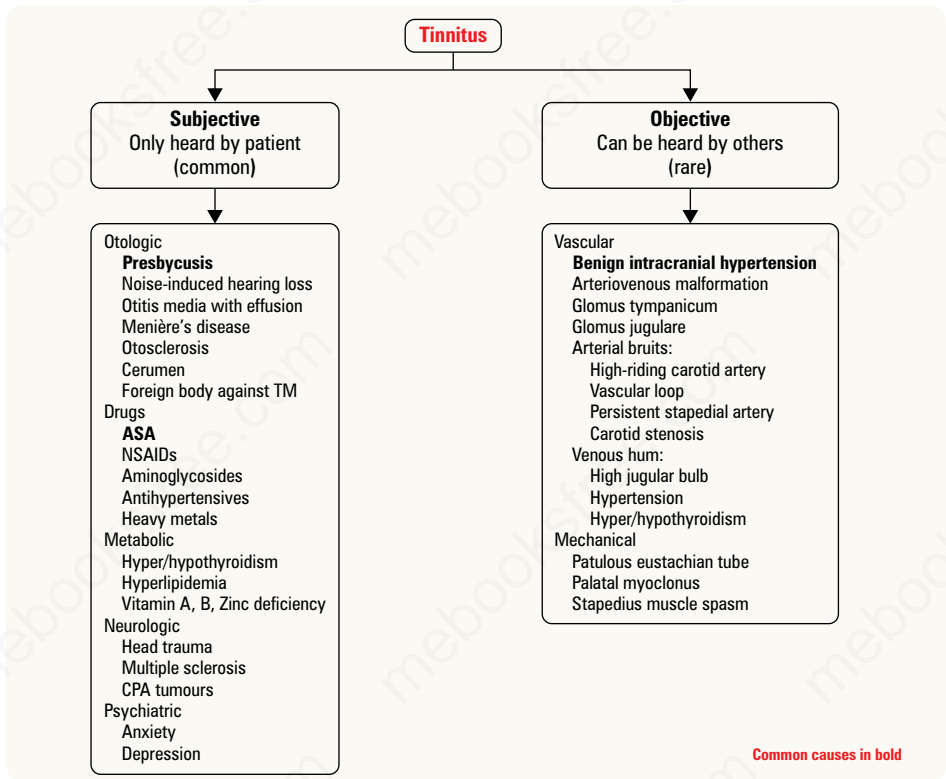

Figure 14. Differential diagnosis of tinnitus

Tinnitus is most commonly associated with SNHL

Glomus Tympanicum/Jugulare Tumour
Signs and Symptoms

- Pulsatile tinnitus
- Hearing loss
- Blue mass behind TM
- Brown's sign (blanching of the TM with pneumatic otoscopy)

Nasal Obstruction

Table 2. Differential Diagnosis of Nasal Obstruction

Acquired	Congenital
Nasal Cavity Rhinitis Acute/chronic Vasomotor Allergic Rhinosinusitis Foreign bodies Enlarged turbinates Tumour Benign: polyps, inverting papilloma Malignant SCC Esthesioneuroblastoma (olfactory neuroblastoma) Adenocarcinoma	Nasal Cavity Nasal dermoid cyst Encephalocele Glioma Choanal atresia
Nasal Septum Septal deviation Septal hematoma/abscess Dislocated septum	Nasal Septum Septal deviation Septal hematoma/abscess Dislocated septum
Nasopharynx Adenoid hypertrophy Tumour Benign: juvenile nasopharyngeal angiofibroma (JNA), polyps Malignant: nasopharyngeal carcinoma	
Systemic Granulomatous diseases, diabetes, vasculitis	

Hoarseness

Table 3. Differential Diagnosis of Hoarseness

Infectious	Acute/chronic laryngitis Laryngotracheobronchitis (croup)	
Inflammatory	GERD Vocal cord polyps/nodules Lifestyle: smoking, chronic EtOH use	
Trauma	External laryngeal trauma Endoscopy and endotracheal tube (e.g. intubation granuloma)	
Neoplasia	Benign tumour Papillomas (HPV infection) Minor salivary gland tumours Other	Malignant tumours (e.g. thyroid) SCC Other
Cysts	Retention cysts	
Systemic	Endocrine Hypothyroidism Virilization	Connective tissue disease RA SLE
Neurologic (vocal cord paralysis due to superior ± recurrent laryngeal nerve injury)	Central lesions Cerebrovascular accident (CVA) Head injury Multiple sclerosis (MS) Skull base tumours Arnold-Chiari malformation Peripheral lesions Unilateral Lung malignancy	Iatrogenic injury: thyroid, parathyroid surgery, carotid endarterectomy, patent ductus arteriosus (PDA) ligation Bilateral Iatrogenic injury: bilateral thyroid surgery, forceps delivery Neuromuscular Myasthenia gravis
Functional	Psychogenic aphonia (hysterical aphonia)	
Congenital	Laryngomalacia Laryngeal web Laryngeal atresia	

Lung malignancy is the most common cause of extralaryngeal vocal cord paralysis

Neck Mass

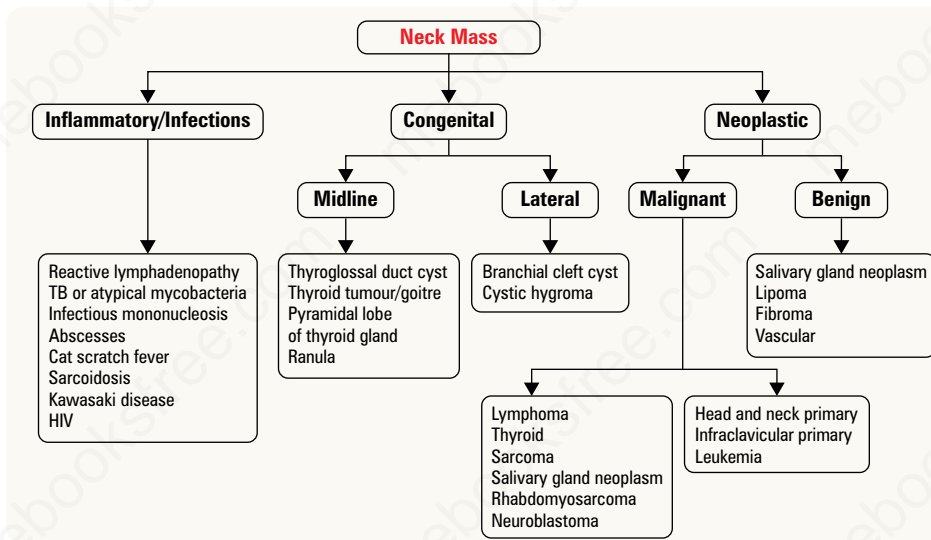

Figure 15. Differential diagnosis of a neck mass

Hearing

Normal Hearing Physiology

- **conductive pathway** (EAC to cochlea): air conduction of sound down the EAC → vibration of TM → sequential vibration of middle ear ossicles (malleus, incus, stapes) → transmission of amplified vibrations from stapes footplate to the oval window of the cochlea → transmitted vibrations via cochlear fluid create movement along the basilar membrane within the cochlea
- **neural pathway** (nerve to brain): basilar membrane vibration stimulates overlying hair cells in the organ of Corti → stimulation of bipolar neurons in the spiral ganglion of the cochlear division of CN VIII → cochlear nucleus → superior olivary nucleus → lateral lemniscus → inferior colliculus → Sylvian fissure of temporal lobe

Order of the Neural Pathway (with corresponding waves on ABR)

E COLI

Eighth cranial nerve (I – II)
Cochlear nucleus (III)
Superior Olivary nucleus
Lateral lemniscus (IV – V)
Inferior colliculus

Types of Hearing Loss

1. Conductive Hearing Loss

- conduction of sound to the cochlea is impaired
- can be caused by external and middle ear disease

2. Sensorineural Hearing Loss

- defect in the conversion of sound into neural signals or in the transmission of those signals to the cortex
- can be caused by disease of the inner ear (cochlea), acoustic nerve (CN VIII), brainstem, or cortex

3. Mixed Hearing Loss

- combination of conductive and sensorineural hearing loss

Auditory Acuity

- whispered-voice test: mask one ear and whisper into the other
- tuning fork tests (see Table 4; audiogram is of greater utility)
 - Rinne test
 - ♦ 512 Hz tuning fork is struck and held firmly on mastoid process to test bone conduction (BC); the tuning fork is then placed beside the pinna to test air conduction (AC)
 - ♦ If AC > BC → positive Rinne (normal)
 - Weber test
 - ♦ 512 Hz tuning fork is held on vertex of head and patient states whether it is heard centrally (Weber negative) or is lateralized to one side (Weber right, Weber left)
 - ♦ can place vibrating fork on patient's chin while they clench their teeth, or directly on teeth to elicit more reliable response
 - ♦ will only lateralize if difference in hearing loss between ears is >6 dB

Weber Test lateralization = ipsilateral conductive hearing loss or contralateral sensorineural hearing loss

The Weber test is more sensitive in detecting conductive hearing loss than the Rinne test

Table 4. The Interpretation of Tuning Fork Tests

Examples	Weber	Rinne
Normal or bilateral sensorineural hearing loss	Central	AC > BC (+) bilaterally
Right-sided conductive hearing loss, normal left ear	Lateralizes to right	BC > AC (-) right
Right-sided sensorineural hearing loss, normal left ear	Lateralizes to left	AC > BC (+) bilaterally
Right-sided severe sensorineural hearing loss or dead right ear, normal left ear	Lateralizes to left	BC > AC (-) right*

*A vibrating tuning fork on the mastoid stimulates the cochlea bilaterally, therefore in this case the left cochlea is stimulated by the Rinne test on the right (e.g. a false negative test). These tests are not valid if the ear canals are obstructed with cerumen (e.g. will create conductive loss)

Frequency of Tuning Fork (Hz)	Minimum Hearing Loss for Rinne to Reverse (BC > AC, NEGATIVE Rinne) (dB)
256	15
512	30
1024	45

- Range of Frequencies Audible to Human Ear**
- 20 to 20000 Hz
 - Most sensitive frequencies: 1000 to 4000 Hz
 - Range of human speech: 500 to 2000 Hz

Hearing loss most often occurs at higher frequencies. Noise-induced (occupational) HL is classically seen at 4000 Hz. HL associated with otosclerosis is seen at 2000 Hz (Carhart's notch)

Pure Tone Audiometry

- a threshold is the lowest intensity level at which a patient can hear the tone 50% of the time
- thresholds are obtained for each ear at frequencies of 250, 500, 1000, 2000, 4000, and 8000 Hz
- air conduction thresholds are obtained with headphones and measure outer, middle, inner ear, and auditory nerve function
- bone conduction thresholds are obtained with bone conduction oscillators which bypass the outer and middle ear

Degree of Hearing Loss

- determined on basis of the pure tone average (PTA) at 500, 1000, and 2000 Hz

Figure 16. Types of hearing loss and associated audiograms of a left ear

PURE TONE PATTERNS

1. Conductive Hearing Loss (Figure 16B and 16C)

- BC in normal range
- AC outside of normal range
- gap between AC and BC thresholds >10 dB (an air-bone gap)

2. Sensorineural Hearing Loss (Figure 16D and 16E)

- both air and bone conduction thresholds below normal
- gap between AC and BC <10 dB (no air-bone gap)

3. Mixed Hearing Loss

- both air and bone conduction thresholds below normal
- gap between AC and BC thresholds >10 dB (an air-bone gap)

Speech Audiometry

Speech Reception Threshold

- lowest hearing level at which patient is able to repeat 50% of two syllable words which have equal emphasis on each syllable (spondee words)
- SRT and best pure tone threshold in the 500 to 2000 Hz range (frequency range of human speech) usually agree within 5 dB; if not, suspect a retrocochlear lesion or functional hearing loss
- used to assess the reliability of the pure tone audiometry

Speech Discrimination Test

- percentage of words the patient correctly repeats from a list of 50 monosyllabic words
- tested at 40 dB above the patient's SRT, therefore degree of hearing loss is taken into account
- patients with normal hearing or conductive hearing loss score >90%
- rollover effect: a decrease in discrimination as sound intensity increases; typical of a retrocochlear lesion (e.g. acoustic neuroma)
- investigate further if scores differ more than 20% between ears, as asymmetry may indicate a retrocochlear lesion
- best predictor of hearing aid response: a poor discrimination score indicates significant neural degeneration and hearing aids may not be the best option for the patient

Impedance Audiometry

Tympanogram

- the Eustachian tube equalizes the pressure between the external and middle ear
- tympanograms graph the compliance of the middle ear system against a pressure gradient ranging from to -400 to +200 mmH₂O
- tympanogram peak occurs at the point of maximum compliance: where the pressure in the external canal is equivalent to the pressure in the middle ear
- normal range: -100 to +50 mmH₂O

Figure 17. Tympanograms

Static Compliance

- volume measurement reflecting overall stiffness of the middle ear system
- normal range: 0.3-1.6 cc
- negative middle ear pressure and abnormal compliance indicate middle ear pathology
- in a type B curve, ear canal volumes of >2 cc in children and >2.5 cc in adults indicate TM perforation or presence of a patent ventilation tube

Acoustic Stapedial Reflexes

- stapedius muscle contracts in response to loud sound
- acoustic reflex threshold = 70-100 dB greater than hearing threshold; if hearing threshold >85 dB, reflex likely absent
 - stimulating either ear causes bilateral and symmetrical reflexes
 - for reflex to be present, CN VII must be intact with no conductive hearing loss in monitored ear
 - if reflex is absent without conductive or severe sensorineural loss, suspect CN VII lesion
- **acoustic reflex decay test** = ability of stapedius muscle to sustain contraction for 10 s at 10 dB
 - normally, little reflex decay occurs at 500 and 1000 Hz
- with cochlear hearing loss, acoustic reflex thresholds are 25-60 dB
- with retrocochlear hearing loss (acoustic neuroma), absent acoustic reflexes or marked reflex decay (>50%) within 5 s

Auditory Brainstem Response

- measures neuroelectric potentials (waves) in response to a stimulus in five different anatomic sites (see *Order of Neural Pathway sidebar on OT9*; this test can be used to determine the site of lesion)
- delay in brainstem response suggests cochlear or retrocochlear abnormalities
- does not require volition or co-operation of patient (therefore, of value in children and malingers)

Otoacoustic Emissions

- objective test of hearing where a series of clicks is presented to the ear and the cochlea generates an echo which can be measured
- often used in newborn screening
- can be used to uncover normal hearing in malingering patients
- absence of emissions can be due to hearing loss or fluid in the middle ear

Aural Rehabilitation

- dependent on degree of hearing loss, communicative requirements, motivation, expectations, and physical and mental abilities
- negative prognostic factors
 - poor speech discrimination
 - narrow dynamic range (recruitment)
 - unrealistic expectations
- types of hearing aids
 - BTE: behind-the-ear (with occlusive mould or open fit which allows natural sound to pass – for milder hearing losses)
 - ITE: in-the-ear, placed in concha
 - ITC: in-the-canal, placed entirely in ear canal
 - CIC: contained-in-canal, placed deeply in ear canal
 - bone conduction – bone-anchored hearing aid (BAHA): attached to the skull
 - contralateral routing of signals (CROS)
- assistive listening devices
 - direct/indirect audio output
 - infrared, FM radio, or induction loop systems
 - telephone, television, or alerting devices
- cochlear implants
 - electrode is inserted into the cochlea to allow direct stimulation of the auditory nerve
 - for profound bilateral sensorineural hearing loss not rehabilitated with conventional hearing aids
 - established indication: post-lingually deafened adults, pre- and post-lingually deaf children

Pre-lingually deaf infants are the best candidates for aural rehabilitation because they have maximal benefit from ongoing developmental plasticity

Bone Anchored Hearing Aids (BAHA)
BAHAs function based on bone conduction and are indicated primarily for patients with conductive hearing loss, unilateral hearing loss, and mixed hearing loss who cannot wear conventional hearing aids. BAHAs consist of a titanium implant, an external abutment, and a sound processor. The sound processor transmits vibrations through the external abutment to the titanium implant and then directly to the cochlea

Pre-lingual deafness: deafness occurring before speech and language are acquired
Post-lingual deafness: deafness occurring after speech and language are acquired

Vertigo

Evaluation of the Dizzy Patient

- vertigo: illusion of rotational, linear, or tilting movement of self or environment
- vertigo is produced by peripheral (inner ear) or central (brainstem-cerebellum) stimulation
- it is important to distinguish vertigo from other potential causes of “dizziness” (see Figure 11, OT6)

Table 5. Peripheral vs. Central Vertigo

Symptoms	Peripheral	Central
Imbalance	Moderate-severe	Mild-moderate
Nausea and Vomiting	Severe	Variable
Auditory Symptoms	Common	Rare
Neurologic Symptoms	Rare	Common
Compensation	Rapid	Slow
Nystagmus	Unidirectional Horizontal or rotatory	Bidirectional Horizontal or vertical

Table 6. Differential Diagnosis of Vertigo Based on History

Condition	Duration	Hearing Loss	Tinnitus	Aural Fullness	Other Features
Benign Paroxysmal Positional Vertigo (BPPV)	Seconds	–	–	–	
Ménière's Disease	Minutes to hours Precedes attack	Uni/bilateral, fluctuating	+	Pressure/warmth	
Labyrinthitis/Vestibular Neuritis	Hours to days	Unilateral	± Whistling	–	May have recent AOM
Acoustic Neuroma	Chronic	Progressive	+	–	Ataxia CN VII palsy

Table 7. Differential Diagnosis of Vertigo Based on Time Course

Time Course	Condition
Recurrent, lasting	BPPV
Single episode, lasting minutes to hours	Migraine, transient ischemia of the labyrinth or brainstem
Recurrent to hours	Ménière's
Prolonged	Vestibular neuritis, MS, brainstem/cerebellum infarct
Acoustic neuroma	Chronic

Benign Paroxysmal Positional Vertigo

Definition

- acute attacks of transient rotatory vertigo lasting seconds to minutes, initiated by certain head positions, accompanied by torsional (i.e. rotatory) nystagmus (geotropic = fast phase towards the floor)
- most common form of positional vertigo (50% of patients with peripheral vestibular dysfunction)

Etiology

- due to canalithiasis (migration of free floating otoliths within the endolymph of the semicircular canal) or cupulolithiasis (otolith attached to the cupula of the semicircular canal)
 - can affect each of the 3 semicircular canals, although the posterior canal is affected in >90% of cases
 - causes: head injury, viral infection (URTI), degenerative disease, idiopathic
 - results in slightly different signals being received by the brain from the two balance organs, resulting in sensation of movement

Diagnosis

- history (time course, provoking factors, associative symptoms)
- positive Dix-Hallpike maneuver (sensitivity 82%, specificity 71%)

Dix-Hallpike Positional Testing (see website for video and illustrations)

- the patient is rapidly moved from a sitting position to a supine position with the head hanging over the end of the table, turned to one side at 45°, and neck extended 20° holding the position for 20 s
- onset of vertigo and rotary nystagmus indicate a positive test for the dependent side
- other diagnostic testing is not indicated in posterior canal BPPV

Treatment

- reassure patient that process resolves spontaneously
- particle repositioning maneuvers
 - Epley maneuver (performed by MD or by patient with the help of devices such as the DizzyFIX™)
 - Brandt-Daroff exercises (performed by patient)
- surgery for refractory cases
- anti-emetics for N/V
- drugs to suppress the vestibular system delay eventual recovery and are therefore not used

Ménière's Disease (Endolymphatic Hydrops)

Definition

- episodic attacks of tinnitus, hearing loss, aural fullness, and vertigo lasting minutes to hours

Proposed Etiology

- inadequate absorption of endolymph leads to endolymphatic hydrops (over accumulation) that distorts the membranous labyrinth

Epidemiology

- peak incidence 40-60 yr
- bilateral in 35% of cases

BPPV is the most common cause of episodic vertigo; patients are often symptomatic when rolling over in bed or moving their head to a position of extreme posterior extension (such as looking up at a tall building or getting their hair washed at the hairdresser)

Signs of BPPV seen with Dix-Hallpike Maneuver

- Latency of ~20 s
- Crescendo/decrecendo vertigo lasting 20 s
- Geotropic rotatory nystagmus (nystagmus MUST be present for a positive test)
- Reversal of nystagmus upon sitting up
- Fatigability with repeated stimulation

Diagnostic Criteria for Ménière's Disease (must have all three)

- Two spontaneous episodes of rotational vertigo ≥20 minutes
- Audiometric confirmation of SNHL (often low frequency)
- Tinnitus and/or aural fullness

Clinical Features

- episodic vertigo, fluctuating low frequency SNHL, tinnitus, and aural fullness
- \pm drop attacks (Tumarkin crisis), \pm N/V
- vertigo disappears with time (min to h), but hearing loss remains
- early in the disease: fluctuating SNHL
- later stages: persistent tinnitus and progressive hearing loss
- attacks come in clusters and can be debilitating to the patient
- triggers: high salt intake, caffeine, stress, nicotine, and alcohol

Treatment

- acute management may consist of bed rest, antiemetics, antivertiginous drugs (e.g. betahistine [Serc[®]], meclizine, dimenhydramine), and anticholinergics (e.g. scopolamine)
- long-term management may include
 - medical
 - ♦ low salt diet, diuretics (e.g. hydrochlorothiazide, triamterene, amiloride)
 - ♦ Serc[®] prophylactically to decrease intensity of attacks
 - ♦ intratympanic gentamicin to destroy vestibular end-organ, results in complete SNHL
 - ♦ intratympanic glucocorticoids (e.g. dexamethasone) may improve vertigo symptoms
 - surgical
 - ♦ selective vestibular neurectomy or labyrinthectomy
 - ♦ potential benefit for endolymphatic sac decompression or sacculotomy
- must monitor opposite ear, as bilaterality occurs in 35% of cases

Vestibular Neuronitis (Labyrinthitis)

Definition

- acute onset of disabling vertigo often accompanied by N/V and imbalance without hearing loss that resolves over days, leaving a residual imbalance that lasts days to weeks
- vestibular neuronitis: inflammation of the vestibular portion of CNVIII
- labyrinthitis: inflammation of both vestibular and cochlear portions

Etiology

- thought to be due to a viral infection (e.g. measles, mumps, herpes zoster) or post-viral syndrome
- only ~30% of cases have associated URTI symptoms
- labyrinthitis may occur as a complication of acute and chronic otitis media, bacterial meningitis, cholesteatoma, and temporal bone fractures

Clinical Features

- acute phase
 - severe vertigo with N/V and imbalance lasting 1-5 d
 - irritative nystagmus (fast phase towards the offending ear)
 - ataxia: patient tends to veer towards affected side
 - tinnitus and hearing loss in labyrinthitis
- convalescent phase
 - imbalance and motion sickness lasting days to weeks
 - spontaneous nystagmus away from affected side
 - gradual vestibular adaptation requires weeks to months

Treatment

- acute phase
 - bed rest, antivertiginous drugs
 - corticosteroids (methylprednisolone) \pm antivirals
 - bacterial infection: treat with IV antibiotics, drainage of middle ear, \pm mastoidectomy
- convalescent phase
 - progressive ambulation, especially in the elderly
 - vestibular exercises: involve eye and head movements, sitting, standing, and walking

Drop Attacks (Tumarkin's Otolithic Crisis) are sudden falls occurring without warning and without LOC, where patient experiences feeling of being pushed down into the ground

Before proceeding with gentamicin treatment, perform a gadolinium enhanced MRI to rule out CPA tumour as the cause of symptoms

Acoustic neuroma is the most common intracranial tumour causing SNHL and the most common cerebellopontine angle tumour

In the elderly, unilateral tinnitus or SNHL is acoustic neuroma until proven otherwise

Acoustic Neuroma (Vestibular Schwannoma)

Definition

- schwannoma of the vestibular portion of CN VIII

Pathogenesis

- starts in the internal auditory canal and expands into cerebellopontine angle (CPA), compressing cerebellum and brainstem
- when associated with type 2 neurofibromatosis (NF2): bilateral acoustic neuromas, juvenile cataracts, meningiomas, and ependymomas

Clinical Features

- usually presents with unilateral SNHL (chronic) or tinnitus
- dizziness and unsteadiness may be present, but true vertigo is rare as tumour growth occurs slowly, and thus compensation occurs

- facial nerve palsy and trigeminal (V1) sensory deficit (corneal reflex) are late complications
- risk factors: exposure to loud noise, childhood exposure to low-dose radiation, history of parathyroid adenoma

Diagnosis

- MRI with gadolinium contrast (gold standard)
- audiogram (to assess SNHL)
- poor speech discrimination relative to the hearing loss
- stapedial reflex absent or significant reflex decay
- ABR: increase in latency of the 5th wave
- vestibular tests: normal or asymmetric caloric weakness (an early sign)

Treatment

- expectant management if tumour is very small, or in elderly
- definitive management is surgical excision
- other options: gamma knife, radiation

Tinnitus

Definition

- an auditory perception in the absence of an acoustic stimuli, likely related to loss of input to neurons in central auditory pathways and resulting in abnormal firing

History

- subjective vs. objective (see Figure 14, OT7)
- continuous vs. pulsatile (vascular in origin)
- unilateral vs. bilateral
- associated symptoms: hearing loss, vertigo, aural fullness, otalgia, otorrhea

Investigations

- audiology
- if unilateral
 - ABR, gadolinium-enhanced MRI to exclude a retrocochlear lesion
 - CT to diagnose glomus tympanicum (rare)
 - MRI or angiogram to diagnose AVM
- if suspect metabolic abnormality: lipid profile, TSH, zinc levels

Treatment

- if a cause is found, treat the cause (e.g. drainage of middle ear effusion, embolization or excision of AVM)
- with no treatable cause: 50% will improve, 25% worsen, 25% remain the same
- avoid loud noise, ototoxic meds, caffeine, smoking
- tinnitus clinics
- identify situations where tinnitus is most bothersome (e.g. quiet times), mask tinnitus with soft music or "white noise"
- hearing aid if coexistent hearing loss
- tinnitus instrument: combines hearing aid with white noise masker
- trial of tocainamide

Diseases of the External Ear

Cerumen Impaction

Etiology

- ear wax: a mixture of secretions from ceruminous and pilosebaceous glands, squames of epithelium, dust, and debris

Risk Factors

- hairy or narrow ear canals, in-the-ear hearing aids, cotton swab usage, osteomata

Clinical Features

- hearing loss (conductive)
- ± tinnitus, vertigo, otalgia, aural fullness

Treatment

- water or cerumenolytic drops (bicarbonate solution, olive oil, glycerine, Cerumenol®, Cerumenex®)
- manual debridement (by MD)

Cerumen impaction is the most common cause of conductive hearing loss for those aged 15-50 yr

Syringing

Indications

- Totally occlusive cerumen with pain, decreased hearing, or tinnitus

Contraindications

- Active infection
- Previous ear surgery
- Only hearing ear
- TM perforation

Complications

- Otitis externa
- TM perforation
- Trauma
- Pain
- Vertigo
- Tinnitus
- Otitis media

Method

- Establish that TM is intact
- Gently pull the pinna superiorly and posteriorly
- Using lukewarm water, aim the syringe nozzle upwards and posteriorly to irrigate the ear canal

Exostoses

Definition

- bony protuberances in the external auditory canal composed of lamellar bone

Etiology

- possible association with swimming in cold water

Clinical Features

- usually an incidental finding
- if large, they can cause cerumen impaction or otitis externa

Treatment

- no treatment required unless symptomatic

Otitis Externa

Definition

- inflammation of external auditory canal or auricle

Etiology

- bacterial (90% of OE): *Pseudomonas aeruginosa*, *Pseudomonas vulgaris*, *E. coli*, *S. aureus*
- fungal: *Candida albicans*, *Aspergillus niger*

Risk Factors

- associated with swimming ("swimmer's ear")
- mechanical cleaning (Q-tips®), skin dermatitis, aggressive scratching
- devices that occlude the ear canal: hearing aids, headphones, etc.
- allergic contact dermatitis, dermatologic conditions (psoriasis, atopic dermatitis)

Clinical Features

- acute
 - pain aggravated by movement of auricle (traction of pinna or pressure over tragus)
 - otorrhea (sticky, yellow purulent discharge)
 - conductive hearing loss ± aural fullness 2° to obstruction of external canal by swelling and purulent debris
 - posterior auricular lymphadenopathy
 - complicated OE exists if the pinna and/or the periauricular soft tissues are erythematous and swollen
- chronic
 - pruritus of external ear ± excoriation of ear canal
 - atrophic and scaly epidermal lining, ± otorrhea, ± hearing loss
 - wide meatus but no pain with movement of auricle
 - tympanic membrane appears normal

Treatment

- clean ear under magnification with irrigation, suction, dry swabbing, and C&S
- bacterial etiology
 - antipseudomonal otic drops (e.g. ciprofloxacin) or a combination of antibiotic and steroid (e.g. Cipro HC®)
 - do not use aminoglycoside if the tympanic membrane (TM) is perforated, because of the risk of ototoxicity
 - introduction of fine gauze wick (pope wick) if external canal edematous
 - ± 3% acetic acid solution to acidify ear canal (low pH is bacteriostatic)
 - systemic antibiotics if either cervical lymphadenopathy or cellulitis is present
- fungal etiology
 - repeated debridement and topical antifungals (gentian violet, Mycostatin® powder, boric acid, Locacorten®, Vioform® drops)
- ± analgesics
- chronic otitis externa (pruritus without obvious infection) → corticosteroid alone (e.g. diprosalic acid)

Pulling on the pinna is extremely painful in otitis externa, but is usually well tolerated in otitis media

Malignant (Necrotizing) Otitis Externa (Skull Base Osteomyelitis)

Definition

- osteomyelitis of the temporal bone

Epidemiology

- occurs in elderly diabetics and immunocompromised patients

Etiology

- rare complication of otitis externa
- *Pseudomonas* infection in 99% of cases

Clinical Features

- otalgia and purulent otorrhea that is refractory to medical therapy
- granulation tissue on the floor of the auditory canal

Complications

- cranial nerve palsy (most commonly CN VII>CN X>CN XI)
- systemic infection, death

Management

- imaging: high resolution temporal bone CT scan, gadolinium-enhanced MRI, technetium scan
- requires hospital admission, debridement, IV antibiotics, hyperbaric O₂
- may require OR for debridement of necrotic tissue/bone

**Gallium and Technetium Scans**

Gallium scans are used to show sites of active infection. Gallium is taken up by PMNs, and therefore only lights up when active infection is present. It will not show the extent of osteomyelitis. Technetium scans provide information about osteoblastic activity and, as a result, are used to demonstrate sites of osteomyelitis. Technetium scans help with diagnosis, whereas gallium scans are useful in follow-up

Diseases of the Middle Ear

Acute Otitis Media and Otitis Media with Effusion

- see *Pediatric Otolaryngology*, OT38

Chronic Otitis Media

Definition

- an ear with TM perforation in the setting of recurrent or chronic ear infections

Benign

- dry TM perforation without active infection

Chronic Serous Otitis Media

- continuous serous drainage (straw-coloured)

Chronic Suppurative Otitis Media

- persistent purulent drainage through a perforated TM

Cholesteatoma

Definition

- a cyst composed of keratinized desquamated epithelial cells occurring in the middle ear, mastoid, and temporal bone
- two types: congenital and acquired

Congenital

- presents as a “small white pearl” behind an intact tympanic membrane (anterior and medial to the malleus) or as a conductive hearing loss
- believed to be due to aberrant migration of external canal ectoderm during development
- not associated with otitis media/Eustachian tube dysfunction

Acquired (more common)

- primary cholesteatoma
 - frequently associated with retraction pockets in the pars flaccida (may lead to attic cholesteatomas, which are difficult to visualize)
 - often has crusting or desquamated debris on lateral surface
- secondary cholesteatoma
 - pearly mass evident behind TM, frequently associated with marginal perforation
 - may appear as skin that have replaced the mucosa of the middle ear
- the associated chronic inflammatory process causes progressive destruction of surrounding bony structures

**Mechanisms of Cholesteatoma Formation**

- Epithelial migration through TM perforation (2° acquired)
- Invagination of TM (1° acquired)
- Metaplasia of middle ear epithelium or basal cell hyperplasia (congenital)

Clinical Features

- history of otitis media (especially if unilateral), ventilation tubes, ear surgery
- symptoms
 - progressive hearing loss (predominantly conductive, although may get sensorineural hearing loss in late stage)
 - otalgia, aural fullness, fever
- signs
 - retraction pocket in TM, may contain keratin debris
 - TM perforation
 - granulation tissue, polyp visible on otoscopy
 - malodorous, unilateral otorrhea

Complications

Table 8. Complications of Cholesteatoma

Local	Intracranial
Ossicular erosion: conductive hearing loss	Meningitis
Inner ear erosion: SNHL, dizziness, and/or labyrinthitis	Sigmoid sinus thrombosis
Temporal bone infection: mastoiditis, petrositis	Intracranial abscess (subdural, epidural, cerebellar)
Facial paralysis	

Investigations

- audiogram and CT scan

Treatment

- there is no conservative therapy for cholesteatoma
- surgical: mastoidectomy ± tympanoplasty ± ossicular reconstruction

Mastoiditis

Definition

- infection (usually subperiosteal) of mastoid air cells, most commonly seen approximately two weeks after onset of untreated or inadequately treated acute suppurative otitis media
- more common in children than adults

Etiology

- acute mastoiditis caused by the same organisms as AOM: *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, *S. pyogenes*, *S. aureus*, *P. aeruginosa*

Clinical Features

- otorrhea
- tenderness to pressure over the mastoid
- retroauricular swelling with protruding ear
- fever, hearing loss, ± TM perforation (late)
- CT radiologic findings: opacification of mastoid air cells by fluid and interruption of normal trabeculations of cells (coalescence)

Classic Triad

- Otorrhea
- Tenderness to pressure over the mastoid
- Retroauricular swelling with protruding ear

Treatment

- IV antibiotics with myringotomy and ventilation tubes – usually all that is required acutely
- cortical mastoidectomy
 - debridement of infected tissue allowing aeration and drainage
- indications for surgery
 - failure of medical treatment after 48 h
 - symptoms of intracranial complications
 - aural discharge persisting for 4 wk and resistant to antibiotics

Complications of AOM are rare due to rapid and effective treatment of AOM with antibiotics

Otosclerosis

Definition

- fusion of stapes footplate to oval window so that it cannot vibrate

Etiology

- autosomal dominant, variable penetrance approximately 40%
- F>M, progresses during pregnancy (hormone responsive)

Clinical Features

- progressive conductive hearing loss first noticed in teens and 20s (may progress to sensorineural hearing loss if cochlea involved)
- ± pulsatile tinnitus
- tympanic membrane normal ± pink blush (Schwartz's sign) associated with the neovascularization of otosclerotic bone
- characteristic dip at 2000 Hz (Carhart's notch) on audiogram (see Figure 16C, OT10)

Otosclerosis is the 2nd most common cause of conductive hearing loss in 15-50 yr old (after cerumen impaction)

Treatment

- monitor with serial audiograms if coping with loss
- hearing aid (air conduction, bone conduction, BAHA)
- stapedectomy or stapedotomy (with laser or drill) with prosthesis is definitive treatment

Diseases of the Inner Ear

Congenital Sensorineural Hearing Loss

Hereditary Defects

- non-syndrome associated (70%)
 - often idiopathic, autosomal recessive
 - connexin 26 (GJB2) most common
- syndrome associated (30%)
 - Waardenburg: white forelock, heterochromia iridis (each eye different colour), wide nasal bridge, and increased distance between medial canthi
 - Pendred: deafness associated with thyroid gland disorders, SLC26A4 gene, enlarged vestibular aqueducts
 - Treacher-Collins: first and second branchial cleft anomalies
 - Alport: hereditary nephritis

Prenatal TORCH Infections

- toxoplasmosis, others (e.g. HIV, syphilis), rubella, CMV, HSV

Perinatal

- Rh incompatibility
- anoxia
- hyperbilirubinemia
- birth trauma (hemorrhage into inner ear)

Postnatal

- meningitis, mumps, measles

High Risk Factors (for hearing loss in newborns)

- low birth weight/prematurity
- perinatal anoxia (low APGARs)
- kernicterus: bilirubin >25 mg/dL
- craniofacial abnormality
- family history of deafness in childhood
- 1st trimester illness: TORCH infections
- neonatal sepsis
- ototoxic drugs
- perinatal infection, including post-natal meningitis
- consanguinity
- 50-75% of newborns with SNHL have at least one of the above risk factors and 90% of these have spent time in the NICU

Treatment

- presence of any risk factor: ABR study performed before leaving NICU and at 3 mo adjusted age
- early rehabilitation improves speech and school performance

Presbycusis

Definition

- SNHL associated with aging (starting in 5th and 6th decades)

Etiology

- hair cell degeneration
- age related degeneration of basilar membrane, possibly genetic etiology
- cochlear neuron damage
- ischemia of inner ear

Clinical Features

- progressive, bilateral hearing loss initially at high frequencies, then middle frequencies
- loss of discrimination of speech, especially with background noise present – patients describe people as mumbling
- recruitment phenomenon: inability to tolerate loud sounds
- tinnitus

Treatment

- hearing aid if patient has difficulty functioning, hearing loss >30-35 dB, and good speech discrimination
- ± lip reading, auditory training, auditory aids (doorbell and phone lights)

Presbycusis is the most common cause of SNHL

Sudden Sensorineural Hearing Loss

Clinical Features

- presents as a sudden onset of significant SNHL (usually unilateral) \pm tinnitus, aural fullness
- usually idiopathic, rule out other causes
 - autoimmune causes (e.g. ESR, rheumatoid factor, ANA)
 - MRI to rule out tumour and/or CT to rule out ischemic/hemorrhagic stroke if associated with any other focal neurological signs (e.g. vertigo, ataxia, abnormality of CN V or VII, weakness)

Treatment

- intratympanic or oral corticosteroids within 3 d of onset: prednisone 1 mg/kg/d for 10-14 d

Prognosis

- depends on degree of hearing loss
- 70% resolve within 10-14 d
- 20% experience partial resolution
- 10% experience permanent hearing loss

Sudden SNHL may easily be confused with ischemic brain events. It is important to keep a high index of suspicion especially with elderly patients presenting with sudden SNHL as well as vertigo

Treatment of Sudden SNHL

Arch Otolaryngol Head Neck Surg 2007;133(6):582-6

Summary

1. Although standard of practice in North America for treating sudden SNHL is systemic steroids, meta-analysis shows no significant benefit of steroids over placebo.
2. There is no difference in addition of antiviral therapy to systemic steroids vs. systemic steroids alone.
3. There was no difference between systemic steroids vs. any other active treatment.

Autoimmune Inner Ear Disease

Etiology

- idiopathic
- may be associated with systemic autoimmune diseases (e.g. rheumatoid arthritis, SLE), vasculitides (e.g. GPA, polyarteritis nodosa), and allergies

Epidemiology

- most common between ages 20-50

Clinical Features

- rapidly progressive or fluctuating bilateral SNHL
- \pm tinnitus, aural fullness, vestibular symptoms (e.g. ataxia, disequilibrium, vertigo)

Investigations

- autoimmune workup: CBC, ESR, ANA, rheumatoid factor

Treatment

- high-dose corticosteroids: treat early for at least 30 d
- consider cytotoxic medication for steroid non-responders

Drug Ototoxicity

Aminoglycosides

- streptomycin and gentamicin (vestibulotoxic), kanamycin, and tobramycin (cochleotoxic)
- toxic to hair cells by any route: oral, IV, and topical (if the TM is perforated)
- destroys sensory hair cells: outer first, inner second (therefore, otoacoustic emissions are lost first)
- high frequency hearing loss develops earliest
- ototoxicity occurs days to weeks post-treatment
- must monitor with peak and trough levels when prescribed, especially if patient has neutropenia and/or history of ear or renal problems
- q24h dosing recommended (with amount determined by creatinine clearance)
- aminoglycoside toxicity displays saturable kinetics, therefore, once daily dosing presents less risk than divided daily doses
- duration of treatment is the most important predictor of ototoxicity
 - treatment: immediately stop aminoglycosides

Salicylates

- hearing loss with tinnitus, reversible if discontinued

Antimalarials (Quinines)

- hearing loss with tinnitus
- reversible if discontinued, but can lead to permanent loss

Others

- many antineoplastic agents are ototoxic (weigh risks vs. benefits)
- loop diuretics

Noise-Induced Sensorineural Hearing Loss

Pathogenesis

- 85-90 dB over months or years or single sound impulses >135 dB can cause cochlear damage
- bilateral SNHL initially and most prominently at 4000 Hz (resonant frequency of the temporal bone), known as “boilermaker’s notch” on audiogram, extends to higher and lower frequencies with time (see Figure 16D, OT10)
- speech reception not altered until hearing loss >30 dB at speech frequency, therefore considerable damage may occur before patient complains of hearing loss
- difficulty with speech discrimination, especially in situations with competing noise

Phases of Hearing Loss

- dependent on: intensity of sound and duration of exposure
 - temporary threshold shift
 - ♦ when exposed to loud sound, decreased sensitivity or increased threshold for sound
 - ♦ may have associated aural fullness and tinnitus
 - ♦ with removal of noise, hearing returns to normal
 - permanent threshold shift
 - ♦ hearing does not return to previous state

Treatment

- hearing aid
- prevention
 - ear protectors: muffs, plugs
 - limit exposure to noise with frequent rest periods
 - regular audiologic follow-up

Temporal Bone Fractures

Table 9. Features of Temporal Bone Fractures

	Transverse (1)	Longitudinal (2)
Extension	Into bony labyrinth and internal auditory meatus	Into middle ear
Incidence	10-20%	70-90%
Etiology	Frontal/occipital trauma	Lateral skull trauma
CN Pathology	CN VII palsy (50%)	CN VII palsy (10-20%)
Hearing Loss	SNHL due to direct cochlear injury	CHL secondary to ossicular injury
Vestibular Symptoms	Sudden onset vestibular symptoms due to direct semicircular canal injury (vertigo, spontaneous nystagmus)	Rare
Other Features	Intact external auditory meatus, TM ± hemotympanum Spontaneous nystagmus CSF leak in Eustachian tube to nasopharynx ± rhinorrhea (risk of meningitis)	Torn TM or hemotympanum Bleeding from external auditory canal Step formation in external auditory canal CSF otorrhea Battle’s sign = mastoid ecchymoses Raccoon eyes = periorbital ecchymoses

- characterized as longitudinal or transverse relative to the long axis of the petrous temporal bone
- temporal bone fractures are rarely purely transverse or longitudinal (often a mixed picture)

Diagnosis

- otoscopy
- do not syringe or manipulate external auditory meatus due to risk of inducing meningitis via TM perforation
- CT head
- audiometry, facial nerve tests (for transverse fractures), Schirmer’s test (of lacrimation), stapedial reflexes if CN VII palsy
- if suspecting CSF leak: look for halo sign, send fluid for β -2 transferrin or β trace protein (prostaglandin D synthase)

Treatment

- ABCs
- medical: expectant, prevent otogenic meningitis
- surgical: explore temporal bone; indications:
 - CN VII palsy (immediate and complete)
 - gunshot wound
 - depressed fracture of external auditory meatus
 - early meningitis (mastoidectomy)
 - bleeding intracranially from sinus
 - CSF otorrhea (may resolve spontaneously)

Figure 18. Types of temporal bone fractures

Hemotympanum can be indicative of temporal bone trauma

Signs of Basilar Skull Fracture
Battle’s Sign

Raccoon Eyes

CSF Rhinorrhea/Otorrhea

Cranial Nerve Involvement:
facial palsy → CN VII,
ystagmus → CN VI,
facial numbness → CN V

Complications

- AOM ± labyrinthitis ± mastoiditis
- meningitis/epidural abscess/brain abscess
- post-traumatic cholesteatoma

Facial Nerve (CN VII) Paralysis

Peripheral Facial Paralysis (PFP)

- mononeuropathy of the facial nerve where there is weakening in the facial muscles, which alters facial symmetry and functions
- can have a detectable cause (secondary facial nerve palsy) or may be idiopathic (primary)

Etiology

- supranuclear and nuclear (MS, poliomyelitis, cerebral tumours)
- infranuclear

Treatment

- treat according to etiology, plus provide corneal protection with artificial tears, nocturnal lid taping, tarsorrhaphy, gold weighting of upper lid
- facial paralysis that does not resolve with time or with medical treatment will often be referred for possible reanimation techniques to restore function
 - common reanimation techniques include
 - ♦ direct facial nerve anastomosis
 - ♦ interpositional grafts
 - ♦ anastomosis to other motor nerves
 - ♦ muscle transpositions

Table 10. Differential Diagnosis of Peripheral Facial Paralysis (PFP)

Etiology	Incidence	Findings	Investigations	Treatment, Follow-up, and Prognosis (Px)
Bell's Palsy Idiopathic, (HSV) infection of the facial nerve Diagnosis of exclusion	80-90% of PFP Risk Factors: DM Pregnancy Viral prodrome (50%)	Hx Acute onset Numbness of ear Schirmer's test Recurrence (12%) + FHx (14%) Hyperacusis (30%) P/E Paralysis or paresis of all muscle groups on one side of the face Absence of signs of CNS disease Absence of signs of ear or CPA diseases	Stapedial reflex absent Audiology normal (or baseline) EMG – best measure for prognosis Topographic testing MRI with gadolinium – enhancement of CN VII and VIII High resolution CT	Rx Protect the eye to prevent exposure keratitis with patching or tarsorrhaphy Systemic steroids may lessen degeneration and hasten recovery Consider antiviral (acyclovir) F/U Spontaneous remission should begin within 3 wk of onset Delayed (3-6 mo) recovery portends at least some functional loss Px ENoG testing between day 3-14 of onset: <90% degeneration=high likelihood of recovery >90% + no voluntary EMG motor unit potentials= surgical decompression Poorer if hyperacusis, >60 yr, DM, HTN, severe pain
Ramsay Hunt Syndrome (Herpes Zoster Oticus) Varicella zoster infection of CN VII/VIII	4.5-9% of PFP Risk Factors: >60 yr Impaired immunity Cancer Radiotherapy Chemotherapy	Hx Hyperacusis SNHL Severe pain of pinna, mouth, or face P/E Vesicles on pinna, external canal (erupt 3-7 d after onset of pain) Associated herpes zoster ophthalmicus (uveitis, keratoconjunctivitis, optic neuritis, or glaucoma)	Stapedial reflex absent Audiology – SNHL Viral ELISA studies to confirm MRI with gadolinium (86% of facial nerves enhance)	Rx Avoid touching lesions to prevent spread of infection Systemic steroids can relieve pain, vertigo, avoid postherpetic neuralgia Acyclovir may lessen pain, aid healing of vesicles F/U: 2-4 wk Px Poorer prognosis than Bell's palsy; 22% recover completely, 66% incomplete paralysis, 10% complete paralysis

TEMPORAL BONE FRACTURE *rarely a patient has a single type of fracture

Longitudinal (90%)	20% have PFP	Hx Blow to side of head P/E Trauma to side of head Neuro findings consistent with epidural/subdural bleed	Skull X-rays CT head	Px Injury usually due to stretch or impingement; may recover with time
Transverse (10%)	40% have PFP	Hx Blow to frontal or occipital area P/E Trauma to front or back of head	Skull X-rays CT head	Px Nerve transection more likely
Iatrogenic		Variable (depending on level of injury)	Wait for lidocaine to wear off EMG	Rx Exploration if complete nerve paralysis No exploration if any movement present Source: Paul Warrick, MD

Rhinitis

Definition

- inflammation of the lining (mucosa) of the nasal cavity

Table 11. Classification of Rhinitis

Inflammatory	Non-Inflammatory
Perennial non-allergic	Rhinitis medicamentosa
Asthma, ASA sensitivity	Topical decongestants
Allergic	Hormonal
Seasonal	Pregnancy
Perennial	Estrogens
Atrophic	Thyroid
Primary: <i>Klebsiella ozena</i> (especially in elderly)	Idiopathic vasomotor
Acquired: post-surgery if too much mucosa or turbinate has been resected	
Infectious	
Viral: e.g. rhinovirus, influenza, parainfluenza, etc.	
Bacterial: e.g. <i>S. aureus</i>	
Fungal	
Granulomatous: TB, syphilis, leprosy	
Non-infectious	
Sarcoidosis	
GPA	
Irritant	
Dust	
Chemicals	
Pollution	

Rhinitis medicamentosa: rebound congestion due to the overuse of intranasal vasoconstrictors; for prevention, use of these medications for only 5-7 d is recommended

Table 12. Nasal Discharge: Character and Associated Conditions

Character	Associated Conditions
Watery/mucoid	Allergic, viral, vasomotor, CSF leak (halo sign)
Mucopurulent	Bacterial, foreign body
Serosanguinous	Neoplasia
Bloody	Trauma, neoplasia, bleeding disorder, hypertension/vascular disease

Allergic Rhinitis (i.e. Hay Fever)

Definition

- rhinitis characterized by an IgE-mediated hypersensitivity to foreign allergens
- acute-and-seasonal or chronic-and-perennial
- perennial allergic rhinitis often confused with recurrent colds

Etiology

- when allergens contact the respiratory mucosa, specific IgE antibody is produced in susceptible hosts
- concentration of allergen in the ambient air correlates directly with the rhinitis symptoms

Epidemiology

- age at onset usually <20 yr
- more common in those with a personal or family history of allergies/atopy

Clinical Features

- nasal: obstruction with pruritus, sneezing
- clear rhinorrhea (containing increased eosinophils)
- itching of eyes with tearing
- frontal headache and pressure
- mucosa: swollen, pale, "boggy"
- seasonal (summer, spring, early autumn)
 - pollens from trees
 - lasts several weeks, disappears, and recurs the following year at same time
- perennial
 - inhaled: house dust, wool, feathers, foods, tobacco, hair, mould
 - ingested: wheat, eggs, milk, nuts
 - occurs intermittently for years with no pattern or may be constantly present

Complications

- chronic sinusitis/polyps
- serous otitis media

Congestion reduces nasal airflow and allows the nose to repair itself (i.e. washes away the irritants). Treatment should focus on the initial insult rather than target this defense mechanism

Diagnosis

- history
- direct exam
- allergy testing

Treatment

- education: identification and avoidance of allergen
- nasal irrigation with saline
- antihistamines (e.g. diphenhydramine, fexofenadine)
- oral decongestants (e.g. pseudoephedrine, phenylpropanolamine)
- topical decongestant (may lead to rhinitis medicamentosa)
- other topicals: steroids (fluticasone), disodium cromoglycate, antihistamines, ipratropium bromide
- oral steroids if severe
- desensitization by allergen immunotherapy

Vasomotor Rhinitis

Definition

- neurovascular disorder of nasal parasympathetic system (vidian nerve) affecting mucosal blood vessels
- nonspecific reflex hypersensitivity of nasal mucosa

Etiology

- temperature change
- alcohol, dust, smoke
- stress, anxiety, neurosis
- endocrine: hypothyroidism, pregnancy, menopause
- parasympathomimetic drugs
- beware of rhinitis medicamentosa: reactive vasodilation due to prolonged use (>5 d) of nasal drops and sprays (Dristan®, Otrivin®)

Clinical Features

- chronic intermittent nasal obstruction, varies from side to side
- rhinorrhea: thin, watery
- mucosa and turbinates: swollen
- nasal allergy must be ruled out

Treatment

- elimination of irritant factors
- parasympathetic blocker (Atrovent® nasal spray)
- steroids (e.g. beclomethasone, fluticasone)
- surgery (often of limited lasting benefit): electrocautery, cryosurgery, laser treatment, or removal of inferior or middle turbinates
- vidian neurectomy (rarely done)
- symptomatic relief with exercise (increased sympathetic tone)

Rhinosinusitis

Definition

- inflammation of the mucosal lining of the sinuses and nasal passages

Pathogenesis of Rhinosinusitis

- ostial obstruction or dysfunctional cilia permit stagnant mucous and, consequently, infection
- all sinuses drain to a common prechamber under the middle meatus called the osteomeatal complex

Classification

- acute: <4 wk
- subacute: 4-8 wk
- chronic: >8-12 wk

Table 13. Etiologies of Rhinosinusitis

Ostial Obstruction	Inflammation	URTI Allergy
	Mechanical	Septal deviation Turbinate hypertrophy Polyps Tumours Adenoid hypertrophy Foreign body Congenital abnormalities (e.g. cleft palate)
	Immune	PA Lymphoma, leukemia Immunosuppressed patients (e.g. neutropenics, diabetics, HIV)
Systemic		Cystic fibrosis Immotile cilia (e.g. Kartagener's)
Direct Extension	Dental	Infection
	Trauma	Facial fractures

Acute Bacterial Rhinosinusitis

Definition

- bacterial infection of the paranasal sinuses and nasal passages lasting >7 d
- clinical diagnosis requiring ≥ 2 major symptoms, and at least one of the symptoms is either nasal obstruction or purulent/discholoured nasal discharge

Major Symptoms (at least 2 of PODS, 1 must be O or D)

- P** Facial Pain/Pressure/fullness
O Nasal Obstruction
D Purulent/discholoured nasal Discharge
S Hyposmia/anosmia (Smell)

Minor Symptoms

- Headache
 Halitosis
 Fatigue
 Dental pain
 Cough
 Ear pain/fullness

Etiology

- bacteria: *S. pneumoniae* (35%), *H. influenzae* (35%), *M. catarrhalis*, *S. aureus*, anaerobes (dental)
- children are more prone to a bacterial etiology, but viral is still more common
- maxillary sinus most commonly affected
- must rule out fungal causes (mucormycosis) in immunocompromised hosts (especially if painless, black or pale mucosa on examination)

Clinical Features

- sudden onset of:
 - nasal blockage/congestion and/or purulent nasal discharge/posterior nasal drip
 - \pm facial pain or pressure, hyposmia, sore throat
- persistent/worsening symptoms >5-7 d or presence of purulence for 3-4 d with high fever
- speculum exam: erythematous mucosa, mucopurulent discharge, pus originating from the middle meatus
- predisposing factors: viral URTI, allergy, dental disease, anatomical defects
- differentiate from acute viral rhinosinusitis (course: <10 d, peaks by 3 d)

Diagnosis

- along with clinical criteria, can confirm radiographically and/or endoscopically using antral puncture for bacterial cultures

Management

- depends on symptom severity (i.e. intensity/duration of symptoms, impact on quality of life)
- mild-moderate: INCS
 - if no response within 72 h, add antibiotics
- severe: INCS + antibiotics
- antibiotics
 - 1st line: amoxicillin x 10 d (TMP-SMX or macrolide if penicillin allergy)
- if no response to 1st line antibiotics within 72 h, switch to 2nd line
 - 2nd line: fluoroquinolones or amoxicillin-clavulanic acid
- adjuvant therapy (saline or HOCL (pediatric sinusitis) irrigation, analgesics, oral/topical decongestant) may provide symptomatic relief
- CT indicated only if complications are suspected

Acute Rhinosinusitis Complications
 Consider hospitalization if any of the following are suspected

Orbital (Chandler's classification)

- Preseptal cellulitis
- Postseptal cellulitis
- Subperiosteal abscess
- Orbital abscess
- Cavernous sinus thrombosis

Intracranial

- Meningitis
- Abscess

Bony

- Subperiosteal frontal bone abscess ("Pott's Puffy tumour")
- Osteomyelitis

Neurologic

- Superior orbital fissure syndrome (CN III/IV/VI palsy, immobile globe, dilated pupils, ptosis, V1 hypoesthesia)
- Orbital apex syndrome (as above, plus neuritis, papilledema, decreased visual acuity)

Use of Single Dose Azithromycin as Treatment of Acute Bacterial Rhinosinusitis

Otolaryngol Head Neck Surg 2005;133(2):194-200

Summary: Single-dose azithromycin microspheres were comparable to 10 days of levofloxacin and may be a safe and effective treatment for acute bacterial rhinosinusitis.

Results: An international, multicentre, double-blind, double-dummy RCT comparing single dose azithromycin vs. 10-day levofloxacin group for treatment of acute bacterial rhinosinusitis. Clinical success were 94.5% (242/256) in the azithromycin group and 92.8% (233/251) in the levofloxacin group.

Chronic Rhinosinusitis

Definition

- inflammation of the mucosa of paranasal sinuses and nasal passages >8-12 wk
- diagnosis requires ≥ 2 major symptoms for >8-12 wk and ≥ 1 objective finding of inflammation of the paranasal sinuses (CT/endoscopy)

Etiology

- unclear etiology but the following may contribute or predispose
 - inadequate treatment of acute rhinosinusitis
 - bacterial colonization/biofilms
 - S. aureus*, *enterobacteriaceae*, *Pseudomonas*, *S. pneumoniae*, *H. influenzae*, β -hemolytic Streptococci
 - fungal infection (e.g. *Aspergillus*, *Zygomycetes*, *Candida*)
 - anatomic abnormality (e.g. lost ostia patency, deviated septum – predisposing factors)
 - allergy/allergic rhinitis
 - ciliary disorder (e.g. cystic fibrosis, Kartagener syndrome)
 - chronic inflammatory disorder (e.g. GPA)
 - untreated dental disease

Clinical Features (similar to acute, but less severe) - at least 2 of CPODS for >8-12 wk

- facial Congestion/fullness
- facial Pain/Pressure
- chronic nasal Obstruction
- purulent anterior/posterior nasal Discharge
- hyposmia/anosmia (Smell)
- others: halitosis, chronic cough, maxillary dental pain

Management

- identify and address contributing or predisposing factors
- obtain CT or perform endoscopy
- if polyps present: INCS, oral steroids \pm antibiotics (if signs of infection), refer to otolaryngologist/H&N surgeon
- if polyps absent: INCS, antibiotics, saline irrigation, oral steroids (severe cases)
- antibiotics for 3-6 wk
 - amoxicillin-clavulanic acid, fluoroquinolone (moxifloxacin), macrolide (clarithromycin), clindamycin, Flagyl® (metronidazole)
- surgery if medical therapy fails or fungal sinusitis: FESS, balloon sinoplasty

Complications

- same as acute sinusitis, mucocele

Allergic fungal rhinosinusitis is a chronic sinusitis affecting mostly young, immunocompetent, atopic individuals. Treatment options include FESS \pm intranasal topical steroids, antifungals, and immunotherapy.

FESS = Functional Endoscopic Sinus Surgery
Opening of the entire osteomeatal complex in order to facilitate drainage while sparing the sinus mucosa.

90% of nose bleeds occur in Little's area

Epistaxis

Blood Supply to the Nasal Septum (see Figure 4, OT3)

- Superior posterior septum
 - internal carotid \rightarrow ophthalmic \rightarrow anterior/posterior ethmoidal
 - Posterior septum
 - external carotid \rightarrow internal maxillary \rightarrow sphenopalatine artery \rightarrow nasopalatine
 - Lower anterior septum
 - external carotid \rightarrow facial artery \rightarrow superior labial artery \rightarrow nasal branch
 - external carotid \rightarrow internal maxillary \rightarrow descending palatine \rightarrow greater palatine
- these arteries all anastomose to form Kiesselbach's plexus, located at Little's area (anterior-inferior portion of the cartilaginous septum)
 - bleeding from above middle turbinate is internal carotid, from below is external carotid

Table 14. Etiology of Epistaxis

Type	Causes	
Local	Trauma (most common) Fractures: facial, nasal Self-induced: digital, foreign body	Tumours Benign: polyps, inverting papilloma, angiofibroma Malignant: SCC, esthesioneuroblastoma (olfactory neuroblastoma)
	Iatrogenic: nasal, sinus, orbit surgery	Inflammation Rhinitis: allergic, non-allergic Infections: bacterial, viral, fungal
	Barometric changes	
	Nasal dryness: dry air ± septal deformities	Idiopathic
	Septal perforation	
	Chemical: cocaine, nasal sprays, ammonia, etc.	
Systemic	Coagulopathies Meds: anticoagulants, NSAIDs Hemophilias, von Willebrand's Hematological malignancies Liver failure, uremia	
	Vascular: HTN, atherosclerosis, Osler-Weber-Rendu (hereditary hemorrhagic telangiectasia)	
	Others: GPA, SLE	

**Special Cases**

- Adolescent male with unilateral recurrent epistaxis - consider juvenile nasopharyngeal angiofibroma (JNA); this is the most common benign tumour of the nasopharynx
- Thrombocytopenic patients: use resorbable packs to avoid risk of re-bleeding caused by pulling out the removable pack

Investigations

- CBC, PT/PTT (if indicated)
- X-ray, CT as needed

Treatment

- locate bleeding and achieve hemostasis

1. ABCs

- lean patient forward to minimize swallowing blood and avoid airway obstruction
- apply constant firm pressure for 20 min on cartilaginous part of nose (not bony pyramid)
- if significant bleeding, assess vitals for signs of hemorrhagic shock ± IV NS, cross-match blood

2. Determine Site of Bleeding

- anterior/posterior hemorrhage defined by location in relationship to bony septum
- visualize nasal cavity with speculum
- use cotton pledget with topical lidocaine ± topical decongestant (i.e. Otrivin®) to help identify area of bleeding (often anterior septum)
- if suspicious bleeding disorder, coagulation workup (platelet number and platelet function assay)

3. Control the Bleeding

- first-line: topical vasoconstrictors (Otrivin®)
- if first-line fails and bleeding adequately visualized, cauterize with silver nitrate
- **do not cauterize both sides of the septum** at one time due to risk of septal perforation from loss of septal blood supply

A. Anterior hemorrhage treatment

- if failure to achieve hemostasis with cauterization
 - ♦ place anterior pack* with half inch Vaseline®-soaked ribbon gauze strips layered from nasal floor toward nasal roof and extending to posterior choanae, or lubricated absorbable packing (i.e. Gelfoam wrapped in Surgicel®) for 2-3 d
 - ♦ can also attempt packing with Merocel® or nasal tampons of different shapes
 - ♦ can also apply Floseal® (hemostatic matrix consisting of topical human thrombin and cross-linked gelatin) if other methods fail

B. Posterior hemorrhage treatment

- if unable to visualize bleeding source, then usually posterior source
 - ♦ place posterior pack* using a Foley catheter, gauze pack, or Epistat® balloon
 - ♦ subsequently, layer anterior packing bilaterally
 - ♦ admit to hospital with packs in for 3-5 d
 - ♦ watch for complications: hypoxemia (naso-pulmonic reflex), toxic shock syndrome (Rx: remove packs immediately), pharyngeal fibrosis/stenosis, alar/septal necrosis, aspiration

C. If anterior/posterior packs fail to control epistaxis

- ligation or embolization of culprit arterial supply by interventional radiology
- ± septoplasty

*antibiotics for any posterior pack or any pack left for >48 h because of risk of toxic shock syndrome

4. Prevention

- prevent drying of nasal mucosa with humidifiers, saline spray, or topical ointments
- avoidance of irritants
- medical management of HTN and coagulopathies

Hoarseness

Definitions

- hoarseness: change in voice quality, ranging from voice harshness to voice weakness; reflects abnormalities anywhere along the vocal tract from oral cavity to lungs
- dysphonia: a general alteration in voice quality
- aphonia: no sound emanates from vocal folds

If hoarseness present for > 2 wk in a smoker, laryngoscopy must be done to rule out malignancy

Acute Laryngitis

Definition

- <2 wk inflammatory changes in laryngeal mucosa

Etiology

- viral: influenza, adenovirus, HSV
- bacterial: Group A *Streptococcus*
- mechanical acute voice strain → submucosal hemorrhage → vocal cord edema → hoarseness
- environmental: toxic fume inhalation

Clinical Features

- URTI symptoms, hoarseness, aphonia, cough attacks, ± dyspnea
- true vocal cords erythematous/edematous with vascular injection and normal mobility

Treatment

- usually self-limited, resolves within ~1 wk
- voice rest
- humidification
- hydration
- avoid irritants (e.g. smoking)
- treat with antibiotics if there is evidence of coexistent bacterial pharyngitis

Vocal Cord Paralysis

Unilateral: affected cord lies in the paramedian position, inadequate glottic closure during phonation → weak, breathy voice. Usually medializes with time, whereby phonation and aspiration improve. Treatment options include voice therapy, injection laryngoplasty (Radiesse), medialization using silastic block

Bilateral: cords rest in midline, therefore voice remains good but respiratory function is compromised and may present as stridor. If no respiratory issues, may monitor closely and wait for improvement. If respiratory issues, intubate and will likely require vocal cord lateralization, arytenoidectomy, posterior costal cartilage graft, or tracheotomy

Chronic Laryngitis

Definition

- >2 wk inflammatory changes in laryngeal mucosa

Etiology

- repeated attacks of acute laryngitis
- chronic irritants (dust, smoke, chemical fumes)
- chronic voice strain
- chronic rhinosinusitis with postnasal drip
- chronic EtOH use
- esophageal disorders: GERD, Zenker's diverticulum, hiatus hernia
- systemic: allergy, hypothyroidism, Addison's disease

Clinical Features

- chronic dysphonia: rule out malignancy
- cough, globus sensation, frequent throat clearing 2° to GERD
- laryngoscopy: cords erythematous, thickened with ulceration/granuloma formation, and normal mobility

Treatment

- remove offending irritants
- treat related disorders (e.g. antisecretory therapy for GERD)
- speech therapy with voice rest
- ± antibiotics ± steroids to decrease inflammation
- laryngoscopy to rule out malignancy

Vocal Cord Polyps

Definition

- structural manifestation of vocal cord irritation
- acutely, polyp forms 2° to capillary damage in the subepithelial space during extreme voice exertion

Etiology

- most common benign tumour of vocal cords
- voice strain (muscle tension dysphonia)
- laryngeal irritants (GERD, allergies, tobacco)

Epidemiology

- 30-50 yr of age
- M>F

Clinical Features

- hoarseness, aphonia, cough attacks \pm dyspnea
- pedicled or sessile polyp on free edge of vocal cord
- typically, polyp asymmetrical, soft, and smooth
- more common on the anterior 1/3 of the vocal cord
- intermittent respiratory distress with large polyps

Treatment

- avoid irritants
- endoscopic laryngeal microsurgical removal if persistent or if high risk of malignancy

Vocal Cord Nodules**Definition**

- vocal cord callus
- i.e. "screamer's or singer's nodules"

Etiology

- early nodules occur 2° to submucosal hemorrhage
- mature nodules result from hyalinization, which occurs with long-term voice abuse
- chronic voice strain
- frequent URTI, smoke, EtOH

Epidemiology

- frequently in singers, children, bartenders, and school teachers
- F>M

Clinical Features

- hoarseness worst at end of day
- on laryngoscopy
 - often bilateral
 - at the junction of the anterior 1/3 and posterior 2/3 of the vocal cords – point of maximal cord vibration
- chronic nodules may become fibrotic, hard, and white

Treatment

- voice rest
- hydration
- speech therapy
- avoid irritants
- surgery rarely indicated for refractory nodules

Benign Laryngeal Papillomas**Etiology**

- HPV types 6, 11
- possible hormonal influence, possibly acquired during delivery

Epidemiology

- biphasic distribution: 1) birth to puberty (most common laryngeal tumour) and 2) adulthood

Clinical Features

- hoarseness and airway obstruction
- can seed into tracheobronchial tree
- highly resistant to complete removal
- some juvenile papillomas resolve spontaneously at puberty
- may undergo malignant transformation
- laryngoscopy shows wart-like lesions in supraglottic larynx and trachea

Treatment

- microdebridement or CO₂ laser
- adjuvants under investigation: interferon, cidofovir, acyclovir
- HPV vaccine may prevent/decrease the incidence, but more research is needed

Laryngeal Carcinoma

- see *Neoplasms of the Head and Neck*, OT34

**Vocal Cords: Polyps vs. Nodules**

Polyps	Nodule
Unilateral, asymmetric	Bilateral
Acute onset	Gradual onset
May resolve spontaneously	Often follow a chronic course
Subepithelial capillary breakage	Acute: submucosal hemorrhage or edema Chronic: hyalinization within submucosal lesion
Soft, smooth, fusiform, pedunculated mass	Acute: small, discrete nodules Chronic: hard, white, thickened fibrosed nodules
Proton pump inhibitor	Voice rest but no whispering, hydration, speech therapy if refractory to therapy
Surgical excision if persistent or in presence of risk factors for laryngeal cancer	Surgical excision as last resort

Salivary Glands

Sialadenitis

Definition

- inflammation of salivary glands

Etiology

- viral most common (mumps)
- bacterial causes: *S. aureus*, *S. pneumoniae*, *H. influenzae*
- obstructive vs. non-obstructive
 - obstructive infection involves salivary stasis and bacterial retrograde flow

Predisposing Factors

- HIV
- anorexia/bulimia
- Sjögren's syndrome
- Cushing's, hypothyroidism, DM
- hepatic/renal failure
- meds that increase stasis: diuretics, TCAs, β -blockers, anticholinergics, antibiotics
- sialolithiasis (can cause chronic sialadenitis)

Clinical Features

- acute onset of pain and edema of parotid or submandibular gland that may lead to marked swelling
- \pm fever
- \pm leukocytosis
- \pm suppurative drainage from punctum of the gland

Investigations

- U/S imaging to differentiate obstructive vs. non-obstructive sialadenitis

Treatment

- bacterial: treat with cloxacillin \pm abscess drainage, sialogogues
- viral: no treatment

Bilateral enlargement of the parotid glands may be a manifestation of a systemic disease, such as Mumps, HIV, Sjögren's or an eating disorder (i.e. anorexia, bulimia)

Mumps usually presents with bilateral parotid enlargement \pm SNHL \pm orchitis

Sialolithiasis

Definition

- ductal stone (mainly hydroxyapatite) in adults, sand/sludge in children, leading to chronic sialadenitis
- 80% in submandibular gland, <20% in parotid gland, ~1% in sublingual gland

Risk Factors

- any condition causing duct stenosis or a change in salivary secretions (e.g. dehydration, diabetes, EtOH, hypercalcemia, psychiatric medication)

Clinical Features

- pain and tenderness over involved gland
- intermittent swelling related to meals
- digital palpation reveals presence of calculus

Investigations

- U/S \pm sialogram

Treatment

- may resolve spontaneously
- encourage salivation to clear calculus
- massage, analgesia, antibiotics, sialogogues (e.g. lemon wedges, sour lemon candies), warm compresses
- remove calculi endoscopically, by dilating duct or orifice, or by excision through floor of the mouth
- gland preserving surgery has long-term symptom improvement and favourable gland retention rates

Salivary Gland Neoplasms

Etiology

- anatomic distribution
 - parotid gland: 70-85%
 - submandibular gland: 8-15%
 - sublingual gland: 1%
 - minor salivary glands, most concentrated in hard palate: 5-8%

- malignant (see Table 15, OT31 and Table 16, OT35)
- benign
 - benign mixed (pleomorphic adenoma): 80%
 - Warthin's tumour (5-10% bilateral, M>F): 10%
 - cysts, lymph nodes, and adenomas: 10%
 - oncocytoma: <1%

Epidemiology

- 3-6% of all head and neck neoplasms in adults
- mean age at presentation: 55-65
- M=F

A mass sitting above an imaginary line drawn between the mastoid process and angle of the mandible is a parotid neoplasm until proven otherwise

DDx Parotid Tumour

Benign

- Pleomorphic adenoma
- Warthin's tumour (more common in men)
- Benign lymphoepithelial cysts (viral etiology e.g. HIV)
- Oncocytoma

Malignant

- Mucoepidermoid carcinoma
- Adenoid cystic carcinoma
- Acinic cell carcinoma

Frey's syndrome is a post-operative complication characterized by gustatory sweating. It is due to aberrant innervation of cutaneous sweat glands by parasympathetic nerve fibres that are divided during surgery

Parotid Gland Neoplasms

Clinical Features

- 80% benign (pleomorphic adenoma: most common), 20% malignant (mucoepidermoid: most common)
- if bilateral, suggests benign process (Warthin's tumour, Sjögren's, bulimia, mumps) or possible lymphoma
- facial nerve involvement (i.e. facial paralysis): increases risk of malignancy

Investigations

- FNA biopsy
- CT, U/S, or MRI to determine extent of tumour

Treatment

- treatment of choice is surgery for all salivary gland neoplasms – benign and malignant
- pleomorphic adenomas are excised due to risk of malignant transformation (5% risk over prolonged period of time)
- superficial tumour
 - superficial parotidectomy above plane of CN VII ± radiation
 - incisional biopsy contraindicated
- deep lesion
 - near-total parotidectomy sparing as much of CN VII as possible
 - if CN VII involved, then it is removed and cable grafted
- complications of parotid surgery
 - hematoma, infection, salivary fistula, temporary facial paresis, Frey's syndrome (gustatory sweating)

Prognosis

- benign: excellent, <5% of pleomorphic adenomas may recur
- malignant: dependent on stage and type of malignancy (see Table 16, OT35)

Neck Masses

Approach to a Neck Mass

- ensure that the neck mass is not a normal neck structure (hyoid, transverse process of C1 vertebra, prominent carotid bulb)
- any neck mass persisting for >2 wk should be investigated for possible neoplastic causes

Table 15. Acquired Causes of Neck Lumps According to Age

Age (yr)	Possible Causes of Neck Lump		
<20	1. Congenital	2. Inflammatory/Infectious	3. Neoplastic
20-40	1. Inflammatory	2. Congenital	3. Neoplastic
>40	1. Neoplastic	2. Inflammatory	3. Congenital

Differential Diagnosis

- congenital
 - lateral (branchial cleft cyst, lymphatic/venous/venolymphatic malformation)
 - midline (thyroglossal duct cyst, dermoid cyst, laryngocele, thyroid/thymus anomaly, vascular malformation)
- infectious/inflammatory
 - reactive lymphadenopathy (2° to tonsillitis, pharyngitis)
 - infectious mononucleosis
 - Kawasaki, Kikuchi, Kimura, Cat-scratch disease, Castleman's
 - HIV
 - salivary gland calculi, sialadenitis
 - thyroiditis

- granulomatous disease
 - mycobacterial infections
 - sarcoidosis
- neoplastic
 - lymphoma
 - salivary gland tumours
 - thyroid tumours
 - metastatic malignancy (“unknown primary”)

Evaluation

Investigations

- history and physical (including nasopharynx and larynx)
- all other investigations and imaging are dependent upon clinical suspicion following history and physical
- laboratory investigations
 - WBC: infection vs. lymphoma
 - Mantoux TB test
 - thyroid function tests and scan
- imaging
 - neck U/S
 - CT scan
 - angiography: vascularity and blood supply to mass
- biopsy: for histologic examination
 - FNA: least invasive
 - needle biopsy
 - open biopsy: for lymphoma
- identification of possible primary tumour (rule out a metastatic lymph node from an “unknown primary”)
 - panendoscopy: nasopharyngoscopy, laryngoscopy, esophagoscopy, bronchoscopy with washings, and biopsy of suspicious lesions
 - biopsy of normal tissue of nasopharynx, tonsils, base of tongue, and hypopharynx
 - primary identified 95% of time → stage and treat
 - primary occult 5% of time: excisional biopsy of node for histologic diagnosis → manage with radiotherapy and/or neck dissection (squamous cell carcinoma)

Inflammatory vs. Malignant Neck Masses

	Inflammatory	Neoplastic
History		
Painful	Y	N
H&N infection	Y	N
Fever	Y	N
Weight loss	N	Y
CA risk factors	N	Y
Age	Younger	Older
Physical		
Tender	Y	N
Rubbery	Y	Occ.
Rock hard	N	Y
Mobile	Y	± fixed

Congenital Neck Masses

Brachial Cleft Cysts/Sinuses/Fistulae

Embryology

- at the 6th wk of development, the 2nd branchial arch grows over the 3rd and 4th arches and fuses with the neighbouring caudal pre-cardial swelling, forming the cervical sinus
- 3 types of malformations
 1. branchial fistula: persistent communication between skin and GI tract
 2. branchial sinus: blind-ended tract opening to skin
 3. branchial cyst: persistent cervical sinus with no external opening

Clinical Features

- 2nd branchial cleft malformations most common
 - sinuses and fistulae present in infancy as a small opening anterior to the sternocleidomastoid muscle
 - cysts present as a smooth, painless, slowly enlarging lateral neck mass, often following a URTI
- 1st branchial cleft malformations present as sinus/fistula or cyst in preauricular area or on face over angle of mandible
- 3rd branchial cleft malformations present as recurrent thyroiditis or thyroid abscess and have a tract leading usually to the left pyriform sinus. Air on CT scan in or near the thyroid gland is pathognomonic for this anomaly
- there is controversy whether or not 4th branchial cleft anomalies exist, as they may be remnants of the thyrothymic axis

Treatment

- surgical removal of cyst or fistula tract
- if infected: allow infection to settle before removal (antibiotics may be required)

Figure 19. Branchial cleft anomalies

Thyroglossal Duct Cysts

Embryology

- thyroid originates as ventral midline diverticulum at base of tongue, caudal to junction of 3rd and 4th branchial arches (foramen cecum), and migrates down to inferior aspect of neck
- thyroglossal duct cysts are vestigial remnants of this tract

Clinical Features

- usually presents in childhood or during 20-40s as a midline cyst that enlarges with URTI and elevates with swallowing and tongue protrusion

Treatment

- pre-operative antibiotics to reduce inflammation (infection before surgery is a well-described cause of recurrence)
- small potential for neoplastic transformation, so complete excision of cyst and tissue around tract up to foramen cecum at base of tongue, with removal of central portion of hyoid bone (Sistrunk procedure) recommended

Lymphatic, Venous, or Mixed Venolymphatic Malformations

Definition

- lymphatic malformation arising from vestigial lymph channels of neck

Clinical Features

- commonly identified in many fetuses, but regress before birth and never cause a clinical problem
- usually present by age 2
- can be macrocystic (composed of large thin-walled cysts, usually below level of mylohyoid muscle) or microcystic (composed of minute cysts, usually above level of mylohyoid muscle)
- usually painless, soft, compressible
- infection or trauma causes a sudden increase in size

Treatment

- can regress spontaneously after bacterial infection, therefore do not plan surgical intervention until several months after infection
- macrocystic lesions can be treated by sclerotherapy or surgical excision
- microcystic lesions are difficult to treat, but can be debulked if it will not cause loss of function of normal structures, or injected with sclerotherapy in surrounding tissues

Neoplasms of the Head and Neck

Pre-Malignant Disease

- leukoplakia
 - hyperkeratosis of oral mucosa
 - risk of malignant transformation 5-20%
- erythroplakia
 - red superficial patches adjacent to normal mucosa
 - commonly associated with epithelial dysplasia
 - associated with carcinoma *in situ* or invasive tumour in 40% of cases
- dysplasia
 - histopathologic presence of mitoses and prominent nucleoli
 - involvement of entire mucosal thickness = carcinoma *in situ*
 - associated progression to invasive cancer in 15-30% of cases

Investigations

- initial metastatic screen includes CXR
- scans of liver, brain, and bone only if clinically indicated
- CT scan is superior to MRI for the detection of pathologic nodal disease and bone cortex invasion
- MRI is superior to discriminate tumour from mucus and to detect bone marrow invasion
- ± PET scans

Treatment

- treatment depends on
 - histologic grade of tumour
 - stage
 - physical and psychological health of patient
 - facilities available
 - expertise and experience of the medical and surgical oncology team
- in general
 - 1° surgery for malignant oral cavity tumours with radiotherapy reserved for salvage or poor prognostic indicators
 - 1° radiotherapy for nasopharynx, oropharynx, hypopharynx, larynx malignancies with surgery reserved for salvage
 - palliative chemotherapy for metastatic or incurable disease
 - concomitant chemotherapy increases survival in advanced disease
 - chemotherapy has a role as induction therapy prior to surgery and radiation
 - panendoscopy to detect primary disease when lymph node metastasis is identified
 - anti-EGFR treatment (cetuximab, panitumumab) has a role as concurrent therapy with radiation for SCC of the head and neck (for advanced local and regional disease)

Prognosis

- synchronous tumours occur in 9-15% of patients
- late development of 2nd primary is most common cause of post-treatment failure after 36 mo

All patients presenting with a head and neck mass should be asked if they are experiencing the following obstructive, referred, or local symptoms

- Dyspnea or stridor (positional vs. non-positional)
- Hoarseness or dysphonia
- Otalgia
- Non-healing oral ulcer
- Dysphagia
- Hemoptysis, hematemesis

Detection of cervical lymph nodes on physical exam
False negative rate: 15-30%
False positive rate: 30-40%

Pathological lymphadenopathy defined radiographically as

- A jugulodigastric node >1.5 cm in diameter, or a retropharyngeal node >1 cm in diameter
- A node of any size which contains central necrosis

Common sites of distant metastases for head and neck neoplasms
lungs > liver > bones

Table 16. Quick Look-Up Summary of Head and Neck Malignancies – Etiology and Epidemiology

Etiology	Epidemiology	Risk Factors
Oral Cavity		
95% SCC others: sarcoma, melanoma, minor salivary gland tumour	Mean age: 50-60 yr M>F Most common site of H&N cancers 50% on anterior 2/3 of tongue	Smoking/EtOH Poor oral hygiene Leukoplakia, erythroplakia Lichen planus, chronic inflammation Sun exposure – lip HPV infection
Nose and Paranasal Sinus		
75-80% SCC Adenocarcinoma (2nd most common) and mucoepidermoid 99% in maxillary/ethmoid sinus 10% of nose and paranasal sinus tumours arise from minor salivary glands	Mean age: 50-70 yr Rare tumours ↓ incidence in last 5-10 yr	Wood/shoe/textile industry Hardwood dust (nasal/ethmoid sinus) Nickel, chromium (maxillary sinus) Air pollution Chronic rhinosinusitis
Carcinoma of the Pharynx – Subtypes (Nasopharynx, Oropharynx, Hypopharynx, and Larynx)		
Nasopharynx		
90% SCC ~10% lymphoma	Mean age: 50-59 yr M:F = 2.4:1 Incidence 0.8 per 100,000 100x increased incidence in Southern Chinese	Epstein-Barr virus (EBV) Salted fish Nickel exposure Poor oral hygiene Genetic – Southern Chinese
Oropharynx		
95% SCC – poorly differentiated Up to 70% of oropharyngeal cancer (OPC) attributable to HPV	Mean age: 50-70 yr Patients with HPV+ OPC are approximately 10 yrs younger Prevalence of HPV+ OPC has increased by 225% from 1988 to 2004. M:F = 4:1	Smoking/EtOH HPV 16 infection: increased sexual encounters, specifically oral sex
Hypopharynx		
95% SCC 3 sites 1. pyriform sinus (60%) 2. post-cricoid (30%) 3. post. pharyngeal wall (10%)	Mean age: 50-70 yr M>F 8-10% of all H&N cancer	Smoking/EtOH
Larynx		
SCC most common 3 sites 1. supraglottic (30-35%) 2. glottic (60-65%) 3. subglottic (1%)	Mean age: 45-75 yr M:F = 10:1 45% of all H&N cancer	Smoking/EtOH HPV 16 infection strongly associated with the risk of laryngeal squamous cell cancers
Salivary Gland		
40% mucoepidermoid 30% adenoid cystic 5% acinic cell 5% malignant mixed 5% lymphoma	Mean age: 55-65 yr M=F 3-6% of all H&N cancer Percentage of malignant tumours in each gland: Parotid 15-25% Submandibular 37-43% Minor salivary >80%	
Thyroid (90% benign – 10% malignant)		
>80% papillary 5-15% follicular 5% medullary <5% anaplastic 1-5% hürthle cell 1-2% metastatic	Children Adults <30 or >60 yr Nodules more common in females Malignancy more common in males	Radiation exposure Family history – papillary CA or multiple endocrine neoplasia – MEN II Older age Male Papillary – Gardner's, Cowden's, familial adenomatous polyposis (FAP)
Parathyroid		
	Mean age: 44-55 yr Rare tumour	

**Risk Factors for Head and Neck Cancer**

- Smoking
- EtOH (synergistic with smoking)
- Radiation
- Occupational/environmental exposures
- Oral HPV infection (independent of smoking and EtOH exposure)

**Survival Comparison between HPV Positive and HPV Negative Head and Neck Squamous Cell Carcinoma**

Int J Cancer 2007;121(8):1813-20

Summary: HPV positive oropharyngeal cancer has better prognosis vs. HPV negative oropharyngeal cancer. It may be a good idea to routinely test for HPV status for all adult patients presenting with oropharyngeal squamous cell carcinoma.

Results: Meta-analysis on relationship between HPV infection and overall survival and disease-free survival in head and neck squamous cell carcinoma. Site-specific analysis for oropharyngeal tumours show that HPV positive group has 28% reduced risk of death (HR 0.72, 95% CI: 0.5-1.0). Similar observations were made for disease-free status (HR: 0.51, 95% CI 0.4-0.7).

**Chemoradiotherapy for Advanced Head and Neck Squamous Cell Carcinoma (HNSCC)**

Radiother Oncol 2009;92(1):4-14

Summary: Cisplatin monochemotherapy or 5-fluorouracil (5-FU) plus cisplatin polychemotherapy should be used in treatment of HNSCC. Concomitant chemotherapy has higher benefit than neo-adjuvant chemotherapy.

Results: Meta-analysis including 87 trials (16,485) comparing regional treatment vs. regional treatment plus chemotherapy in HNSCC patients. Cisplatin monochemotherapy or 5-FU plus cisplatin polychemotherapy had the highest effect of chemotherapy. Both direct and indirect comparisons showed a more pronounced benefit of concomitant chemotherapy (HR 0.81, absolute benefit 6.5% at 5 years) vs. neo-adjuvant chemotherapy (HR 0.88, absolute benefit 4.5% at 5 years). There is no good evidence for adjuvant chemotherapy (HR 1.06, p=0.32).

The smaller the salivary gland, the greater the likelihood that a mass in the gland is malignant

Table 17. Quick Look-Up Summary of Head and Neck Malignancies – Diagnosis and Treatment

Clinical Features	Investigations	Treatment	Prognosis
Oral Cavity			
Asymptomatic neck mass (30%) Non-healing ulcer ± bleeding Dysphagia, sialorrhea, dysphonia Oral fetor, otalgia, leukoplakia, or erythroplakia (pre-malignant changes or CIS)	Biopsy CT	1° surgery local resection ± neck dissection ± reconstruction 2° radiation	5 yr survival T1/T2: 75% T3/T4: 30-35% Poor prognostic indicators Depth of invasion, close surgical margins location (tongue worse than floor of mouth) Cervical nodes, extra-capsular spread
Nose and Paranasal Sinus			
Early Symptoms Unilateral nasal obstruction Epistaxis, rhinorrhea	CT/MRI Biopsy	Surgery and radiation Chemoradiotherapy	5 yr survival: 30-60% Poor prognosis 2° to late presentation
Late Symptoms 2° to invasion of nose, orbit, nerves, oral cavity, skin, skull base, cribriform plate			
Nasopharynx			
Cervical nodes (60-90%) Nasal obstruction, epistaxis Unilateral otitis media ± hearing loss CN III to VI, IX to XII (25%) Proptosis, voice change, dysphagia	Nasopharyngoscopy Biopsy CT/MRI	1° radiation, chemoradiation Surgery for limited or recurrent disease	5 yr survival T1: 79% T2: 72% T3: 50-60% T4: 36-42%
Oropharynx			
Odynophagia, otalgia Ulcerated/enlarged tonsil Fixed tongue/trismus/dysarthria Oral fetor, bloody sputum HPV+ OPC predominantly arises at base of tongue or tonsillar region Cervical lymphadenopathy (60%) Distant mets: lung/bone/liver (7%)	Biopsy Determine HPV status via RT=PCR: positive if presence of HPV DNA and p16 overexpression CT	1° radiation 2° surgery local resection ± neck dissection ± reconstruction	5 year overall survival Stratified by TMN stage (I, II, III, IV) HPV negative OPC (70%, 58%, 50%, 30%) HPV positive OPC (88%, 78%, 71%, 74%) HPV positive OPC further stratified by stage, age and smoking pack years (PY) group I (T1-3N0-N2c, ≤20 PY): 89% group II (T1-3N0-N2c, >20 PY): 64% group III (T4 or N3, age ≤70): 57% group IVA (T4 or N3, age >70): 40%
Hypopharynx			
Dysphagia, odynophagia Otalgia, hoarseness Cervical lymphadenopathy	Pharyngoscopy Biopsy CT	1° radiation 2° surgery	5 yr survival T1: 53% T2/T3: 36-39% T4: 24%
Larynx			
Dysphagia, odynophagia, globus Otalgia, hoarseness Dyspnea/stridor Cough/hemoptysis Cervical nodes (rare with glottic CA)	Laryngoscopy CT/MRI	1° radiation 2° surgery 1° surgery for bulky T4 disease	5 yr survival T4: >40% (surgery with radiation) Control rate early lesions >90% (radiation) 10 to 12% of small lesions fail radiotherapy
Salivary Gland			
Painless mass (occ. pain is possible) CN VII palsy Cervical lymphadenopathy Rapid growth Invasion of skin Constitutional signs/symptoms	FNA MRI/CT/U/S	1° surgery ± neck dissection Post-operative radiotherapy Chemotherapy if unresectable	Parotid 10 yr survival: 85, 69, 43, and 14% for stages T1 to T4 Submandibular 2 yr survival: 82%, 5 yr: 69% Minor salivary gland 10 yr survival: 83, 52, 25, 23% for stages T1 to T4
Thyroid			
Thyroid mass, cervical nodes Vocal cord paralysis Hyper/hypothyroidism Dysphagia	FNA U/S	1° surgery ¹³¹ I for intermediate and high risk well differentiated thyroid cancer	Recurrences occur within 5 yr Need long-term follow-up: clinical exam, thyroglobulin
Parathyroid			
Increased serum Ca ²⁺ Neck mass Bone disease, renal disease Pancreatitis	Sestamibi	Wide surgical excision Post-operative monitoring of serum Ca ²⁺	Recurrence rates 1 yr: 27% 5 yr: 82% 10 yr: 91% Mean survival: 6-7 yr

Thyroid Carcinoma

Table 18. Bethesda Classification of Thyroid Cytology

Category	Risk of Malignancy
Non-diagnostic or unsatisfactory	Unknown
Benign	0-3%
Follicular lesion of undetermined significance/ Atypia of undetermined significance	5-15%
Follicular/hürthle cell neoplasms	15-30%
Suspicious for malignancy	60-75%
Malignant	97-99%

Table 19. Thyroid Carcinoma

	Papillary	Follicular	Medullary	Anaplastic	Lymphoma
Incidence (% of all thyroid cancers)	70-80%	10-15%	1 to 2% (90% sporadic, 10% familial – test for RET germline mutation)	<2%	<1%
Route of Spread	Lymphatic	Hematogenous	Lymphatic and hematogenous		
Histology	Orphan Annie nuclei Psammoma bodies Papillary architecture	Capsular/vascular invasion Invasion influences prognosis	Amyloid May secrete calcitonin, prostaglandins, ACTH, serotonin, kallikrein, or bradykinin	Giant cells Spindle cells	
Other	Ps – Papillary cancer Popular (most common) Palpable lymph nodes Positive I ¹³¹ uptake Positive prognosis Post-operative I ¹³¹ scan to guide treatments	Fs – Follicular cancer Far away mets Female (3:1) NOT FNA (cannot be diagnosed by FNA) Favourable prognosis	Ms – Medullary cancer Multiple endocrine neoplasia (MEN IIa or IIb) aMyloid Median node dissection	More common in elderly 70% in women 20-30% have Hx of differentiated thyroid Ca (mostly papillary) or nodular goitre mass Rapidly enlarging neck Rule out lymphoma	Usually non-Hodgkin's lymphoma Rapidly enlarging thyroid mass Hx of Hashimoto's thyroiditis increases risk 60x 4:1 female predominance dysphagia, dyspnea, stridor, hoarseness, neck pain, facial edema, accompanied by "B" symptoms*
Prognosis	98% at 10 yr	92% at 10 yr	50% at 10 yr 20% at 10 yr if detected when clinically palpable	20-35% at 1 yr 13% at 10 yr	5 yr survival Stage IE 55%-80% Stage IIE 20%-50% Stage IIE/IV 15%-35%
Treatment	Small tumours: Near total thyroidectomy or lobectomy Diffuse/bilateral: Total thyroidectomy ± neck dissection ± post-operative I ¹³¹ treatment	Small tumours: Near total thyroidectomy/lobectomy/isthmectomy Large/diffuse tumours: Total thyroidectomy	Total thyroidectomy Median and/or lateral compartment node neck dissection (based on serum calcitonin) Modified neck dissection Post-operative thyroxine, radiotherapy Tracheostomy Screen relatives	Subtotal thyroidectomy, radiation, chemotherapy, palliative care Small tumours: Total thyroidectomy ± external beam	Non-surgical Combined radiation Chemotherapy (CHOP**)

*B symptoms = fever, night sweats, chills, weight loss >10% in 6 mo

** CHOP = cyclophosphamide, adriamycin, vincristine, prednisone

Approach to Thyroid Nodule

- all patients with thyroid nodules require evaluation of serum TSH and ultrasound
- intermediate-high suspicion nodule >1 cm and low suspicion nodule >1.5 cm should undergo FNA
- nodules <1 cm with clinical symptoms or lymphadenopathy may require further evaluation
- when performing repeat FNA on initially non-diagnostic nodules, U/S-guided FNA should be employed
- nuclear scanning has minimal value in the investigation of the thyroid nodule

Table 20. Management of the Thyroid Nodule

Treatment	Indications
Radioiodine therapy	For the treatment of hyperthyroidism or as adjuvant treatment after surgery in the treatment of intermediate-high risk papillary or follicular carcinoma
Chemotherapy and/or radiotherapy	Recurrent/residual medullary CA, anaplastic CA or thyroid lymphoma
Surgical excision	Nodule that is suspicious on FNA cytology Malignancy other than anaplastic CA or thyroid lymphoma Mass that on FNA is benign but increasing in size on serial imaging and/or >3-4 cm in size Hyperthyroidism not amenable to medical therapy

*U/S findings: cystic: risk of malignancy <1%; solid: risk of malignancy ~10%; solid with cystic components: risk of malignancy same as if solid

Indications for Post-Operative Radioactive Iodine Ablation – I¹³¹
Adjuvant therapy: decrease recurrent disease
RAI therapy: treat persistent cancer

Pediatric Otolaryngology

Acute Otitis Media

Definition

- all of: presence of middle ear effusion (MEE); presence of middle ear inflammation (MEI); acute onset of symptoms of MEE and MEI

Epidemiology

- most frequent diagnosis in sick children visiting clinicians' offices and most common reason for antibiotic administration
- peak incidence between 6-15 mo; ~85% of children have >1 episode by 3 yr old
- seasonal variability: peaks in winter

Etiology

- primary defect causing AOM: Eustachian tube dysfunction/obstruction → stasis/colonization by pathogens
- bacterial: *S. pneumoniae*, non-typable *H. influenzae*, *M. catarrhalis*, Group A *Streptococcus*, *S. aureus*
- viral: RSV, influenza, parainfluenza, adenovirus
- commonly due to bacterial/viral co-infection

Predisposing Factors

- Eustachian tube dysfunction/obstruction
 - swelling of tubal mucosa
 - ◆ upper respiratory tract infection (URTI)
 - ◆ allergic rhinitis
 - ◆ chronic rhinosinusitis
 - obstruction/infiltration of Eustachian tube ostium
 - ◆ tumour: nasopharyngeal carcinoma (adults)
 - ◆ adenoid hypertrophy (by maintaining a source of infection rather than obstruction)
 - ◆ barotrauma (sudden changes in air pressure)
 - inadequate tensor palati function: cleft palate (even after repair)
 - abnormal Eustachian tube
 - ◆ Down syndrome (horizontal position of Eustachian tube), Crouzon syndrome, cleft palate, and Apert syndrome
- disruption of action of:
 - cilia of Eustachian tube: Kartagener's syndrome
 - mucus secreting cells
 - capillary network that provides humoral factors, PMNs, phagocytic cells
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, cystic fibrosis

Risk Factors

- non-modifiable: young age, family history of OM, prematurity, orofacial abnormalities, immunodeficiencies, Down syndrome, race, and ethnicity
- modifiable: lack of breastfeeding, day care attendance, household crowding, exposure to cigarette smoke and air pollution, pacifier use

Pathogenesis

- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features

- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers
 - ear-tugging (this alone is not a good indicator of pathology)
 - hearing loss, balance disturbances (rare)
 - irritable, poor sleeping
 - vomiting and diarrhea
 - anorexia
- otoscopy of TM
 - hyperemia
 - bulging, pus may be seen behind TM
 - loss of landmarks: handle and long process of malleus not visible

Clinical Assessment of AOM in Pediatrics

JAMA 2010;304:2161-69

In assessment of AOM in pediatrics, ear pain is the most useful symptom with a likelihood ratio (LR) between 3.0-7.3. Useful otoscopic signs include erythematous (LR 8.4, 95% CI 7-11), cloudy (LR 34, 95% CI 28-42), bulging (LR 51, 95% CI 36-73), and immobile tympanic membrane (LR 31, 95% CI 26-37) on pneumatic otoscopy.

Diagnosis

- history
 - acute onset of otalgia or ear tugging in a preverbal child, otorrhea, decreased hearing
 - unexplained irritability, fever, upper respiratory symptoms, poor sleeping, anorexia, N/V, and diarrhea
- physical
 - febrile
 - MEE on otoscopy: immobile tympanic membrane, acute otorrhea, loss of bony landmarks, opacification of TM, air-fluid level behind TM
 - MEI on otoscopy: bulging TM with marked discolouration (hemorrhagic, red, grey, or yellow)

Management

- supportive care and symptom management: maintain hydration, analgesic, and antipyretic (acetaminophen, ibuprofen)
- watchful waiting: in a generally healthy child >6 mo of age with unilateral non-severe suspected AOM
 - without MEE, OR with MEE but non-bulging or mildly erythematous TM
 - ♦ consider viral etiology
 - ♦ reassess in 24-48 h if not clinically improved (or earlier if worsening)
 - mildly ill (alert, responsive, no rigors, mild otalgia, fever <39 °C, <48 h illness) with MEE present AND bulging TM
 - ♦ recommend analgesia
 - ♦ observe and follow-up in 24-48 h – if not improved or worsening, treat with antimicrobials
- antimicrobials indicated: infants <6 mo of age, or in a generally healthy child >6 mo of age with suspected AOM and the following features
 - moderately or severely ill (irritable, difficulty sleeping, poor antipyretic response, severe otalgia) OR fever ≥ 39 °C OR > 48 h of symptoms
 - ♦ treat with antimicrobials: 10 d course if 6-24 mo, 5 d if ≥ 2 yr old
 - perforated TM with purulent drainage
 - ♦ treat with antimicrobials for 10 d
- referral to otolaryngology for myringotomy and tympanostomy tubes may be warranted for recurrent infections

Treatment

- antimicrobial agents for AOM
 - 5 d course of appropriate dose antimicrobial recommended for most ≥ 2 yr old with uncomplicated AOM. 10 d course for 6-24 mo, and perforated TM or recurrent AOM
 - 1st line treatment (no penicillin allergy)
 - ♦ amoxicillin: 5 d course of 45-60 mg/kg/d divided 3x/d, or 75-90 mg/kg/d divided 2x/d
 - 2nd line treatment
 - ♦ cefprozil: 30 mg/kg/d divided 2x/d
 - ♦ cefuroxime axetil: 30 mg/kg/d divided 2-3x/d (1st line for penicillin allergy)
 - ♦ ceftriaxone: 50 mg/kg IM (or IV) x 3 doses (1st line for penicillin allergy)
 - ♦ azithromycin: 10 mg/kg OD x 1 dose, then 5 mg/kg OD x 4 doses
 - ♦ clarithromycin: 15 mg/kg/d divided 2x/d
 - if initial therapy fails (i.e. no symptomatic improvement after 2-3 d)
 - ♦ amoxicillin-clavulanate: 45-60 mg/kg/d (7:1 formulation, 400 mg/5 mL suspension) for 10 d for child weighing ≤ 35 kg, or 500 mg tablets TID for 10 d for child weighing >35kg
 - ♦ if AOM-related symptoms do not resolve with amoxicillin/clavulanate, a course of ceftriaxone 50 mg/kg/d IM (or IV) OD x 3 doses could be considered

Complications

- extracranial
 - hearing loss and speech delay (secondary to persistent MEE), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction, persistent effusion (often leading to hearing loss)
- intracranial
 - meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis, facial nerve paralysis
- other
 - mastoiditis, labyrinthitis, sigmoid sinus thrombophlebitis

Antibiotics for Acute Otitis Media in Children

Cochrane DB Syst Rev 2013;1:CD000219

Study: Meta-analysis of Randomized Controlled Trials (RCTs) on children (1-15 mo) with acute otitis media comparing any antibiotic regime to placebo and expectant observation.

Data Sources: Cochrane Central Register of Controlled Trials (2012 issue 10), MEDLINE (1966 to October 2012), OLDMEDLINE (1958 to 1965), EMBASE (January 1990 to November 2012), Current Contents (1966 to November 2012), CINAHL (2008 to November 2012) and LILACS (2008 to November 2012) without language restrictions.

Main Outcomes: 1) Pain at 24 h, 2-3 d, and 4-7 d; 2) Abnormal tympanometry findings; 3) TM perforation; 4) Contralateral otitis; 5) AOM recurrences; 6) Serious complications from AOM; 7) Adverse effects from antibiotics.

Results: Treatment with antibiotics had no significant impact on pain at 24 h. However, pain at 2-3 d and 4-7 d was lower in the antibiotic groups with a NNT of 20. Antibiotics had no significant effect on tympanometry findings, number of AOM recurrences, or severity of complications. Antibiotic treatment led to a significant reduction in TM perforations (NNT 33) and halved contralateral AOM (NNT 11). Adverse events (vomiting, diarrhea, or rash) occurred more often in children taking antibiotics.

Conclusion: The role of antibiotics is largely restricted to pain control at 2-7 d, but most (82%) settle without antibiotics. This can also be achieved by analgesics. However, antibiotic treatment can reduce risk of TM perforation and contralateral AOM episodes. These benefits must be weighed against risks of adverse events from antibiotics.

Otitis Media with Effusion

Definition

- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology

- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- frequently follows AOM in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10% (i.e. 90% of children clear the fluid within 3 mo – observe for 3 mo before considering myringotomy and tubes)

Risk Factors

- same as AOM

Clinical Features

- conductive hearing loss \pm tinnitus
 - confirm with audiogram and tympanogram (flat) (see Figure 16B, OT10 and Figure 17B, OT11)
- fullness – blocked ear
- \pm pain, low grade fever
- otoscopy of tympanic membrane
 - discolouration – amber or dull grey with “glue” ear
 - meniscus fluid level behind TM
 - air bubbles
 - retraction pockets/TM atelectasis
 - most reliable finding with pneumatic otoscopy is immobility

Treatment

- expectant: 90% resolve by 3 mo
 - watchful waiting for 3 mo from onset, or 3 mo from diagnosis if onset unknown
- document hearing loss with audiogram
- no clinical evidence that antihistamines, decongestants, or antibiotics clear disease faster
- recommend **against** intranasal or systemic steroids, systemic antibiotics, antihistamines, decongestants for OME treatment
- surgery: myringotomy \pm ventilation tubes to equalize pressure and drain ear (tympanostomy tubes recommended) \pm adenoidectomy (not recommended in <4 yr old unless nasal obstruction, chronic adenoiditis; recommended in \geq 4 yr old)

Complications of Otitis Media with Effusion

- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma, especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

**Indications for Myringotomy and Tympanostomy Tubes in Recurrent AOM (RAOM) and OME***

- Chronic bilateral OME and documented hearing difficulties $>$ 3 mo
- Unilateral or bilateral OME $>$ 3 mo and symptoms likely attributable to OME (e.g. balance problems, poor school performance, ear discomfort, etc.)
- At-risk children (permanent hearing loss, speech/language delay, autism-spectrum disorder, syndromes/craniofacial disorders, blindness, cleft palate, developmental delay) with unilateral or bilateral OME with type B tympanogram or persistent effusion $>$ 3 mo
- RAOM ($>$ 3 episodes in 6 mo or $>$ 4 in 12 mo) with unilateral or bilateral middle ear effusion

*Clinical practice guidelines: Tympanostomy tubes in children. Otolaryng Head Neck 2013;149:S1-S35

Complications of Otitis Media with Effusion

- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma, especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Adenoid Hypertrophy

- size peaks at age 5 and resolves by age 12
- increase in size with repeated URTI and allergies

Clinical Features

- nasal obstruction
 - adenoid facies (open mouth, high arched palate, narrow midface, malocclusion)
 - history of hypernasal voice and snoring
 - long-term mouth breather; minimal air escape through nose
- choanal obstruction
 - chronic rhinosinusitis/rhinitis
 - obstructive sleep apnea
- chronic inflammation
 - nasal discharge, post-nasal drip, and cough
 - cervical lymphadenopathy

Diagnosis

- enlarged adenoids on nasopharyngeal exam (usually with flexible nasopharyngoscope)
- enlarged adenoid shadow on lateral soft tissue x-ray

Complications

- Eustachian tube obstruction leading to serous otitis media
- interference with nasal breathing, necessitating mouth-breathing
- malocclusion
- sleep apnea/respiratory disturbance
- orofacial developmental abnormalities

Adenoidectomy

Indications for Adenoidectomy

- chronic upper airway obstruction with sleep disturbance/apnea \pm cor pulmonale
- chronic nasopharyngitis resistant to medical treatment
- chronic serous otitis media and chronic suppurative otitis media (with 2nd set of tubes)
- recurrent acute otitis media resistant to antibiotics
- suspicion of nasopharyngeal malignancy
- persistent rhinorrhea secondary to nasal obstruction

**Figure 20. Waldeyer's ring**

An interrupted circle of protective lymphoid tissue at the upper ends of the respiratory and alimentary tracts

Contraindications

- uncontrollable coagulopathy
- recent pharyngeal infection
- conditions that predispose to velopharyngeal insufficiency (cleft palate, impaired palatal function, or enlarged pharynx)

Complications

- bleeding, infection
- velopharyngeal insufficiency (hypernasal voice or nasal regurgitation)
- scarring of Eustachian tube orifice

Sleep-Disordered Breathing in Children

Definition

- spectrum of sleep-related breathing abnormalities ranging from snoring to OSA

Epidemiology

- peak incidence between 2-8 yr when tonsils and adenoids are the largest relative to the pharyngeal airway

Etiology

- due to a combination of anatomic and neuromuscular factors
 - adenotonsillar hypertrophy
 - craniofacial abnormalities
 - neuromuscular hypotonia (i.e. cerebral palsy, Down syndrome)
 - obesity

Clinical Features

- heavy snoring, mouth breathing, pauses or apnea, enuresis, excessive daytime sleepiness, behavioural/learning problems, diagnosis of ADHD, morning headache, failure to thrive, sleeping with neck hyperextended, cyanosis

Investigations

- flexible nasopharyngoscopy for assessment of nasopharynx and adenoids
- polysomnography (apnea-hypopnea index $>1/h$ considered abnormal)
 - children: Mild OSA ≥ 1 to $<5/h$; Moderate OSA ≥ 5 to $<10/h$; Severe OSA $\geq 10/h$
 - adults: Mild OSA 5.1-15/h; Moderate OSA 15.1-30/h; Severe OSA $>30.1/h$

Treatment

- nonsurgical: CPAP, BiPAP, sleep hygiene, weight loss in overweight/obese child with OSA
- medication: topical nasal steroids and leukotriene-receptor antagonists for mild OSA or residual sleep-disordered breathing post-adenotonsillectomy
- surgical: bilateral tonsillectomy and adenoidectomy is first surgery of choice
 - if persistent obstructive sleep apnea following tonsillectomy and adenoidectomy, consider adenoid regrowth
 - if these fail and not tolerant of PAP therapy, consider lingual tonsillectomy, midline glossectomy, or other surgeries targeting areas of resistance as required (STAR surgery); surgery may be guided by Drug-Induced Sleep Endoscopy (DISE) or CINE-MRI to localize site of resistance

Acute Tonsillitis

- see [Pediatrics, P52](#)

Peritonsillar Abscess (Quinsy)

Definition

- cellulitis of space behind tonsillar capsule extending onto soft palate, leading to abscess

Etiology

- bacterial: Group A strep (GAS) (50% of cases), *S. pyogenes*, *S. aureus*, *H. influenzae*, and anaerobes

Epidemiology

- can develop from acute tonsillitis with infection spreading into plane of tonsillar bed
- unilateral
- most common in 15-30 yr age group

Clinical Features

- trismus (due to irritation and reflex spasm of the medial pterygoid) is the most reliable indicator of peritonsillar abscess
- fever and dehydration
- sore throat, dysphagia, and odynophagia
- extensive peritonsillar swelling but tonsil may appear normal

**Quinsy Triad**

- Trismus
- Uvular deviation
- Dysphonia ("hot potato voice")

- edema of soft palate
- uvular deviation
- dysphonia (edema → failure to elevate palate) 2° to CN X involvement
- unilateral referred otalgia
- cervical lymphadenitis

Complications

- aspiration pneumonia 2° to spontaneous rupture of abscess
- airway obstruction
- lateral dissection into parapharyngeal and/or carotid space
- bacteremia
- retropharyngeal abscess

Treatment

- secure airway
- surgical drainage (incision or needle aspiration) with C&S
- warm saline irrigation
- IV penicillin G x 10 d if cultures positive for GAS
- add PO/IV metronidazole or clindamycin x 10 d if culture positive for Bacteroides
- consider tonsillectomy after second episode

Other Sources of Parapharyngeal Space Infections

- pharyngitis
- acute suppurative parotitis (see *Salivary Glands*, OT30)
- AOM
- mastoiditis (Bezold's abscess)
- odontogenic infection

Tonsillectomy

Absolute Indications

- most common indication: sleep-disordered breathing
- 2nd most common indication: recurrent throat infections
- tonsillar hypertrophy causing upper airway obstruction, obstructive sleep apnea, severe dysphagia, or cardiopulmonary complications such as cor pulmonale
- suspicion of malignancy (e.g. lymphoma, squamous cell carcinoma)
- orofacial/dental deformity
- hemorrhagic tonsillitis

Relative Indications (To Reduce Disease Burden)

- recurrent throat infection with a frequency of at least 7 episodes in the past year, at least 5 episodes per year for 2 yr, or at least 3 episodes per year for 3 yr, with documentation in the medical record for each episode of sore throat and 1 or more of the following: temperature >38.3 °C, cervical adenopathy, tonsillar exudate, or positive test for Group A β-hemolytic *Streptococcus* (Paradise Criteria)
- chronic tonsillitis with halitosis (bad breath) or sore throat ± tonsilloliths (clusters of material that form in the crevices of the tonsils)
- complications of tonsillitis: quinsy/peritonsillar abscess, parapharyngeal abscess, retropharyngeal abscess
- failure to thrive

Relative Contraindications

- velopharyngeal insufficiency: overt or submucous/covert cleft of palate, impaired palatal function due to neurological or neuro-muscular abnormalities
- hematologic: coagulopathy, anemia
- infectious: active local infection without urgent obstructive symptoms

Complications

- hemorrhage: primary (within 24 h); secondary (within first 7-10 d)
- odynophagia and/or otalgia; dehydration 2° to odynophagia
- infection
- atlantoaxial subluxation (Grisel's syndrome) - rare

Airway Problems in Children

DIFFERENTIAL DIAGNOSIS BY AGE GROUP

Neonates (Obligate Nose Breathers)

- extralaryngeal
 - choanal atresia (e.g. CHARGE syndrome)
 - nasopharyngeal dermoid, glioma, encephalocele
 - glossoposis: Pierre-Robin sequence, Down syndrome, lymphatic malformation, hemangioma

- laryngeal
 - laryngomalacia: most common cause of stridor in children
 - vocal cord palsy (due to trauma or Arnold-Chiari malformation)
 - glottic web
 - subglottic stenosis
 - laryngeal cleft
 - laryngocele
- tracheal
 - tracheoesophageal fistula
 - tracheomalacia
 - vascular rings
 - complete tracheal rings

2-3 Months

- congenital
 - laryngomalacia
 - vascular: subglottic hemangioma (more common), innominate artery compression, double aortic arch
 - laryngeal papilloma
- acquired
 - subglottic stenosis: post-intubation
 - tracheal granulation: post-intubation
 - tracheomalacia: post-tracheotomy and TEF repair

Infants – Sudden Onset

- foreign body aspiration
- croup
- bacterial tracheitis
- caustic ingestion
- epiglottitis

Children and Adults

- infection
 - Ludwig's angina
 - peritonsillar/parapharyngeal abscess
 - retropharyngeal abscess
- neoplastic
 - squamous cell carcinoma (SCC) (adults): larynx, hypopharynx
 - retropharyngeal: lymphoma, neuroblastoma
 - nasopharyngeal: carcinoma, rhabdomyosarcoma
- allergic
 - angioneurotic edema
 - polyps (suspect cystic fibrosis in children)
- trauma
 - laryngeal fracture, facial fracture
 - burns and lacerations
 - post-intubation
 - caustic ingestion
- congenital
 - lingual thyroglossal duct cyst
 - lingual tonsil hypertrophy
 - lingual thyroid

Signs of Airway Obstruction

Stridor

- note quality, timing (inspiratory or expiratory)
- body position important
 - lying prone: double aortic arch
 - lying supine: laryngomalacia, glossoptosis
- site of stenosis
 - vocal cords or above: inspiratory stridor
 - subglottis and extrathoracic trachea: biphasic stridor
 - distal tracheobronchial tree: expiratory stridor

Respiratory Distress

- nasal flaring
- supraclavicular and intercostal indrawing
- sternal retractions
- use of accessory muscles of respiration
- tachypnea
- cyanosis
- altered LOC

Feeding Difficulty and Aspiration

- supraglottic lesion
- laryngomalacia
- vocal cord paralysis
- laryngeal cleft → aspiration pneumonia
- TEF

Acute Laryngotracheobronchitis (Croup)

Definition

- inflammation of tissues in subglottic space ± tracheobronchial tree
- swelling of mucosal lining and associated with thick, viscous, mucopurulent exudate which compromises upper airway (subglottic space is narrowest portion of upper airway)
- normal function of ciliated mucous membrane impaired

Etiology

- viral: parainfluenzae I (most common), II, III, influenza A and B, RSV

Clinical Features

- age: 4 mo-5 yr
- preceded by URTI symptoms
- generally occurs at night
- biphasic stridor and croupy cough (loud, sea-lion bark)
- appear less toxic than epiglottitis
- supraglottic area normal
- rule out foreign body and subglottic stenosis
- “steeples-sign” on AP X-ray of neck
- if recurrent croup, think subglottic stenosis

Treatment

- racemic epinephrine via MDI q1-2h prn (only if in respiratory distress)
- systemic corticosteroids (e.g. dexamethasone 0.5 mg/kg, prednisone)
- adequate hydration
- close observation for 3-4 h
- intubation if severe (use smaller endotracheal tube than expected for age)
- hospitalize if poor response to steroids after 4 h and persistent stridor at rest
- consider alternate diagnosis if poor response to therapy (e.g. bacterial tracheitis)
- if recurrent episodes of croup-like symptoms, perform high kV croup series X-ray (AP and lat) when well to rule out underlying subglottic stenosis and consider bronchoscopy for definitive diagnosis

Signs of Croup

The 3 Ss

- Stridor
- Subglottic swelling
- Sea bark cough

Acute Epiglottitis

Definition

- acute inflammation causing swelling of supraglottic structures of the larynx without involvement of vocal cords

Etiology

- *H. influenzae* type b
- relatively uncommon condition due to Hib vaccine

Clinical Features

- any age, most commonly 1-4 yr
- rapid onset
- toxic-looking, fever, anorexia, restlessness
- cyanotic/pale, inspiratory stridor, slow breathing, lungs clear with decreased air entry
- prefers sitting up (“tripod” posture), open mouth, drooling, tongue protruding, sore throat, dysphagia

Investigations and Management

- investigations and physical exam may lead to complete obstruction, thus preparations for intubation or tracheotomy must be made prior to any manipulation
- stat ENT/anesthesia consult(s)
- WBC (elevated), blood and pharyngeal cultures after intubation
- lateral neck radiograph (only done if patient stable)

Treatment

- secure airway
- IV access with hydration
- antibiotics: IV cefuroxime, cefotaxime, or ceftriaxone
- moist air
- extubate when leak around tube occurs and afebrile
- watch for meningitis

Acute epiglottitis is a medical emergency

When managing epiglottitis, it is important not to agitate the child, as this may precipitate complete obstruction

Thumb sign: cherry-shaped epiglottic swelling seen on lateral neck radiograph

Subglottic Stenosis

Congenital

- diameter of subglottis <4 mm in neonate (due to thickening of soft tissue of subglottic space or maldevelopment of cricoid cartilage)

Acquired

- following prolonged, repeated, or traumatic intubation
 - most commonly due to endotracheal intubation; nasal intubation is less traumatic and preferred in long-term intubation, as it puts less pressure on the subglottis (tube sits at different orientation) and there is less movement
 - subglottic stenosis is related to duration of intubation and pressure of the endotracheal tube cuff
- can also be due to foreign body, infection (e.g. TB, diphtheria, syphilis), or chemical irritation

Clinical Features

- biphasic stridor
- respiratory distress
- recurrent/prolonged croup

Diagnosis

- rigid laryngoscopy and bronchoscopy

Treatment

- if soft stenosis: divide tissue with knife or laser, dilate with balloon ± steroids
- if firm stenosis: laryngotracheoplasty

Laryngomalacia

- short aryepiglottic folds, omega-shaped epiglottis, pendulous mucosa
- caused by indrawing of supraglottis on inspiration, leading to laryngopharyngeal reflux of acid

Clinical Features

- high-pitched inspiratory stridor at 1-2 wk
- stridor is constant or intermittent and more pronounced supine and following URTI
- usually mild, but can be associated with cyanosis or feeding difficulties when severe, leading to failure to thrive

Treatment

- observation ± proton pump inhibitor (to break the acid reflux cycle that leads to edema and worse airway obstruction) is usually sufficient, as symptoms spontaneously subside by 12-18 mo in >90% of cases
- if severe, division of the aryepiglottic folds (supraglottoplasty) provides relief

Foreign Body

Ingested

- usually stuck at cricopharyngeus muscle
- coins, toys, batteries (**emergency**)
- presents with drooling, dysphagia, stridor if very large

Aspirated

- usually stuck at right main bronchus
- peanuts, carrot, apple core, popcorn, balloons
- presentation
 - stridor if lodged in trachea
 - unilateral "asthma" if bronchial, therefore often misdiagnosed as asthma
 - if totally occludes airway: cough, lobar pneumonia, atelectasis, mediastinal shift, pneumothorax, death

Diagnosis and Treatment

- sudden onset, not necessarily febrile or elevated WBC
- any patient with suspected foreign body should be kept NPO immediately
- older patient: inspiratory-expiratory chest X-ray (if patient is stable)
- younger patient: right and left decubitus chest X-rays. Lack of lung deflation while resting on dependent side suggests foreign body blocking bronchus
- bronchoscopy or esophagoscopy with removal

Laryngomalacia is the most common cause of stridor in infants

Foreign body inhalation is the most common cause of accidental death in children

Batteries **MUST** be ruled out as a foreign body (vs. coins) as they are lethal and can erode through the esophagus. Batteries have a halo sign around the rim on AP x-ray and a step deformity on lateral x-ray

Deep Neck Space Infection

- most commonly arise from an infection of the mandibular teeth, tonsils, parotid gland, deep cervical lymph nodes, middle ear, or the sinuses
- often a rapid onset and may progress to fatal complications

Etiology

- usually mixed aerobes and anaerobes that represent the flora of the oral cavity, upper respiratory tract, and certain parts of the ears and eyes

Clinical Features

- sore throat or pain and trismus
- dysphagia and odynophagia
- stridor and dyspnea
- late findings may include dysphonia and hoarseness
- swelling of the face and neck, erythema
- asymmetry of the oropharynx with purulent oral discharge
- lymphadenopathy

Diagnosis

- lateral cervical view plain radiograph
- CT
- MRI

Treatment

- secure the airway
- surgical drainage
- maximum doses of IV systemic antimicrobials regimens according to the site of infection

These investigations should be obtained carefully and the surgeon should consider accompanying the patient, as the worst place to lose an airway is during imaging

Ludwig's angina is the prototypical infection of the submandibular and sublingual space

Common Medications

Table 21. Antibiotics

Generic Name (Brand Name)	Dose	Indications	Notes
amoxicillin (Amoxil [®] , Amoxi [®] , Amox [®])	Adult: 500 mg PO tid Children: 75-90 mg/kg/d in 2 divided doses	<i>Streptococcus</i> , <i>Pneumococcus</i> , <i>H. influenzae</i> , <i>Proteus</i> coverage	May cause rash in patients with infectious mononucleosis
piperacillin with tazobactam (Zosyn [®])	3 g PO q6h	Gram-positive and negative aerobes and anaerobes plus <i>Pseudomonas</i> coverage	May cause pseudomembranous colitis
ciprofloxacin (Cipro [®] , Ciloxan [®])	500 mg PO bid	<i>Pseudomonas</i> , Streptococci, MRSA, and most Gram- negative; no anaerobic coverage	Animal studies suggest that systemic quinolones may cause cartilage necrosis in children
erythromycin (Erythrocin [®] , EryPed [®] , Staticin [®] , T-Stat [®] , Erybid [®] , Novorythro Encap [®])	500 mg PO qid	Alternative to penicillin	Ototoxic

Table 22. Otic Drops

Generic Name (Brand Name)	Dose	Indications	Notes
ciprofloxacin (Ciprodex [®])	4 gtt in affected ear bid	For otitis externa and complications of otitis media <i>Pseudomonas</i> , Streptococci, MRSA, and most Gram-negative; no anaerobic coverage	
neomycin, polymyxin B sulfate, and hydrocortisone (Cortisporin Otic [®])	5 gtt in affected ear tid	For otitis externa Used for inflammatory conditions which are currently infected or at risk of bacterial infections	May cause hearing loss if placed in inner ear
hydrocortisone and acetic acid (VoSol HC [®])	5-10 gtt in affected ear tid	For otitis media	Bactericidal by lowering pH
tobramycin and dexamethasone (TobraDex [®])	5-10 gtt in affected ear bid	For chronic suppurative otitis media	Risk of vestibular or cochlear toxicity

Table 23. Nasal Sprays

Generic Name (Brand Name)	Indications	Notes
Steroid		
flunisolide (Rhinalar®)	Allergic rhinitis	Requires up to 4 wk of consistent use to have effect
budesonide (Rhinocort®)	Chronic sinusitis	Long-term use
triamcinolone (Nasacort®)		Dries nasal mucosa; may cause minor bleeding
beclomethasone (Beconase®)		Patient should stop if epistaxis
mometasone furoate, monohydrate (Nasonex®)		May sting
fluticasone furoate (Avamys®)		Flonase® and Nasonex® not absorbed systemically
Antihistamine		
levocabastine (Livostin®)	Allergic rhinitis	Immediate effect If no effect by 3 d then discontinue Use during allergy season
Decongestant		
xylometazoline (Otrivin®)	Acute sinusitis	Careful if patient has hypertension
oxymetazoline (Dristan®)	Rhinitis	Short-term use (<5 d)
phenylephrine (Neosynephrine®)		If long-term use, can cause decongestant addiction (i.e. rhinitis medicamentosa)
Antibiotic/Decongestant		
framycetin, gramicidin, phenylephrine (Soframycin®)	Acute sinusitis	
Anticholinergic		
ipratropium bromide (Atrovent®)	Vasomotor rhinitis	Careful not to spray into eyes as can cause burning or precipitation of narrow angle glaucoma Increased rate of epistaxis when combined with topical nasal steroids
Lubricants		
saline, NeilMed®, Rhinaris®, Secaris®, Polysporin®, Vaseline®	Dry nasal mucosa	Use prn Rhinaris® and Secaris® may cause stinging

Pediatric Quick Reference Values

Table 1. Average Vitals at Various Ages

Age (years)	Pulse (bpm)	Respiratory Rate (br/min)	sBP (mmHg)
<1	110-160	30-40	70-90
1-2	100-150	25-35	80-95
2-5	95-140	25-35	80-100
5-12	80-120	20-25	90-110
>12	60-100	15-20	110-120

Primary Care

Visit Overview

- schedule
 - newborn (within 1 wk post-discharge), 1, 2, 4, 6, 9, 12, 15, 18, 24 mo
 - annually between age 2-5; every 1-2 years between age 6-18
- content
 - history and physical exam including growth, development, and nutrition
 - routine immunizations
 - counselling and anticipatory guidance

Routine Immunization

Table 2. Publicly Funded Immunization Schedule for Ontario, December 2016

Age	DTaP-IPV-Hib	dTaP-IPV	Pneu-C-13	Rot-1	Men-C-C	MMR	Var	MMRV	Men-ACYW	HepB	HPV-4	Tdap	Inf
2 mo	✓IM		✓IM	✓PO									
4 mo	✓IM		✓IM	✓PO									
6 mo	✓IM												
12 mo			✓IM		✓IM	✓SC							
15 mo							✓SC						
18 mo	✓IM												
4-6 yr		✓IM						✓SC					
Grade 7									✓IM	✓IM 3 doses (0,1,6 mo)	✓IM 3 doses (0,2,6 mo)		
14-16 yr												✓IM	
Every autumn													✓IM

IM = intramuscular; PO = per oral; SC = subcutaneous

Vaccine	Adverse Reaction	Contraindication
DTaP-IPV	Prolonged crying Hypotonic unresponsive state (rare) Seizure on day of vaccine (rare)	Evolving unstable neurologic disease Hyporesponsive/hypotonic following previous vaccine Anaphylactic reaction to neomycin or streptomycin
Rot-1	Cough Diarrhea, vomiting	History of intussusception Immunocompromised Abdominal disorder (e.g. Meckel's diverticulum) Received blood products (e.g. immunoglobulin) within 42 d
MMR	Measle-like rash (7-14 d) Lymphadenopathy, arthralgia, arthritis Parotitis (rare) Especially painful injection Transient thrombocytopenia (1/30,000)	Pregnancy Immunocompromised infants (except healthy HIV positive children) Anaphylactic reaction to gelatin
Var	Mild varicella-like papules or vesicles; 2 wk may get local or generalized rash	Pregnant or planning to get pregnant within 3 mo Anaphylactic reaction to gelatin
HepB		Anaphylactic reaction to Baker's yeast
MMRV	Same as MMR and Var vaccines	Same as MMR and Var vaccines
dTAP		1st trimester pregnancy
Inf	Malaise, myalgia Febrile seizure when given with Pneu-C 13 or DTaP Hypersensitivity reaction	<6 mo of age Immunocompromised Egg-allergic individuals – Live attenuated influenza vaccine is not recommended for those with an egg allergy. In these individuals, trivalent or quadrivalent vaccine can be given in environment where anaphylaxis can be managed
HPV-4*	Pruritis	
MenB**		Anaphylactic reaction to MenB vaccine or its components in the past

* Males 9-26 yrs: Currently only publicly funded for men who have sex with men

** Currently only publicly funded for select groups (asplenia, antibody/complement deficiencies, cochlear implant recipients, HIV, close contacts with infected individuals)

dTAP = diphtheria, tetanus, acellular pertussis vaccine; DTaP-IPV = diphtheria, tetanus, acellular pertussis, inactivated polio vaccine (i.e. Pentacel®, Pentavax®);

HepB = hepatitis B vaccine; Hib = Haemophilus influenzae type b conjugate vaccine; HPV-4 = human papillomavirus vaccine; Inf = influenza vaccine;

MMR = measles, mumps, rubella vaccine; Men = multicomponent meningococcal B vaccine; Men-C-C = meningococcal c conjugate vaccine;

MMRV = measles, mumps, rubella, varicella vaccine; Pneu-C-13 = pneumococcal 13-valent conjugate vaccine; Rot-1 = rotavirus oral vaccine; Var = varicella vaccine

Canadian Immunization Guide
National Advisory Committee on Immunization. Canadian Immunization Guide (CIG). Last Modified 2014. Public Health Agency of Canada, 2006. Available at: <http://www.phac-aspc.gc.ca/publicat/cig-gci/>

According to the CDC, the weight of currently available scientific evidence does not support the hypothesis that MMR vaccine causes either autism or IBD. The landmark paper linking autism to the MMR vaccine (*Lancet* 1998;351:637-641) was retracted due to false claims in the article (*Lancet* 2010;375:445)

Adverse Reactions Associated With Any Vaccine

- **Local:** induration, tenderness, redness, swelling
- **Systemic:** fever, rash, irritability
- **Allergic:** urticaria, rhinitis, anaphylaxis
- Contraindications
- Moderate/severe illness ± fever
- Allergy to vaccine component
- No need to delay vaccination for mild URTI

Vaccination in Cases of Asplenia or Hyposplenia (such as Sickle Cell Disease)

- Should receive all routine immunizations, including the yearly influenza vaccine
- No vaccines are contraindicated
- Susceptible to infection by encapsulated bacteria ("SHINE KISS" – *S. pneumoniae*, *H. influenzae*, *N. meningitidis*, *E. coli*, *Klebsiella*, *Salmonella*, Group B *Strep*), so must add:
 - Meningococcal-C-Conjugate at age ≥2 yr + Quadrivalent Men-P-ACYW at least 2 wk later
 - Booster of Men-P-ACYW q2-5yr
 - Pneumococcal polysaccharide vaccine (Pneu-P-23) at age ≥2 yr
 - Single booster of Pneu-P-23 at age ≥3 yr
 - Consider single booster Hib at age >5 yr

Injection site
Infants (<12 mo): anterolateral thigh

Growth and Development

Growth

- growth is not linear
 - most rapid growth during first 2 yr and at puberty
 - tissues grow at different times
 - ♦ first 2 yr = CNS; mid-childhood = lymphoid tissue; puberty = gonads
- measurement of growth
 - premature infants (<37 wk) use corrected GA until age 2
 - body proportion = upper/lower segment ratio (use symphysis pubis as midpoint)
 - ♦ newborn = 1.7, adult male = 0.9, adult female = 1.0

Average Growth Parameters

Table 3. Parameter of Average Growth at Birth

	Normal	Growth	Comments
Birth Weight	3.25 kg (7 lbs)	Gain 20-30 g/d (term neonate) 2 x birth wt by 4-5 mo 3 x birth wt by 1 yr 4 x birth wt by 2 yr	Weight loss (up to 10% of birth weight) in first 7 d of life is normal Neonate should regain birth weight by ~10-14 d of age
Length/Height	50 cm (20 in)	25 cm in 1st yr 12 cm in 2nd yr 8 cm in 3rd yr then 4-7 cm/yr until puberty 1/2 adult height at 2 yr	Measure supine length until 2 yr of age, then measure standing height
Head Circumference	35 cm (14 in)	2 cm/mo for 1st 3 mo 1 cm/mo at 3-6 mo 0.5 cm/mo at 6-12 mo	Measure around occipital, parietal, and frontal prominences to obtain the greatest circumference

Reflexes

Table 4. Reflexes

Reflex	Maneuver to Elicit Reflex	Appropriate Reflex Response	Age of Disappearance
Moro	Infant placed semi-upright, head supported by examiner's hand, sudden withdrawal of supported head with immediate return of support	Abduction and extension of the arms, opening of the hands, followed by flexion and adduction of arms	4-6 mo
Galant	Infant held in ventral suspension and one side of back is stroked along paravertebral line	Pelvis will move in the direction of stimulated side	2-3 mo
Grasp	Placement of examiner's finger in infant's palm	Flexion of infant's fingers	3-4 mo
ATNR	Turn infant's head to one side	"Fencing" posture (extension of ipsilateral leg and arm and flexion of contralateral arm)	4-6 mo
Placing	Dorsal surface of infant's foot placed touching edge of table	Flexion followed by extension of ipsilateral limb up onto table (resembles primitive walking)	variable
Rooting	Tactile stimulus near mouth	Infant turns head and opens mouth to suck on same side that cheek was stroked	2-3 mo
Parachute	Tilt infant to side while in sitting position	Ipsilateral arm extension, present by 6-8 mo	Does not disappear

ATNR = asymmetric tonic neck reflex

Developmental Milestones

Table 5. Developmental Milestones

Age*	Gross Motor	Fine Motor	Speech and Language	Adaptive and Social Skills
1 mo	Turns head side to side when supine	Hands fisted, thumb in fist	Cries, startles to loud noises	Calms when comforted
2 mo	Briefly raises head when prone, holds head erect when upright	Pulls at clothes	Variety of sounds (e.g. coos, gurgles)	Smiles responsively, recognizes and calms down to familiar voice, follows movement with eyes
4 mo	Lifts head and chest when prone, holds head steady when supported sitting, rolls prone to supine	Briefly holds object when placed in hand, reaches for midline objects	Turns head towards sounds	Laughs responsively, follows moving toy or person with eyes, responds to people with excitement (e.g. leg movement)
6 mo	Tripod sit, pivots in prone position	Ulnar or raking grasp, transfers objects from hand to hand, brings objects to mouth	Babbles	Stranger anxiety, beginning of object permanence
9 mo	Sits well without support, crawls, pulls to stand, stands with support	Early pincer grasp with straight wrist	"Mama, dada" – appropriate, imitates 1 word, responds to "no" regardless of tone	Plays games (e.g. peek-a-boo), reaches to be picked up
12 mo	Gets into sitting position without help, stands without support, walks while holding on	Neat pincer grasp, releases ball with throw	2 words, follows 1-step command, uses facial expression, sounds, actions to make needs known	Responds to own name, separation anxiety begins

*Use corrected GA until 2 yr

Safety and Efficacy of an Attenuated Vaccine Against Severe Rotavirus Gastroenteritis

NEJM 2006;354:11-22
Purpose: To evaluate the safety and efficacy of an attenuated G1P[8] human rotavirus (HRV) vaccine.
Methods: Randomized, double-blind, phase 3 trial including healthy infants from Latin America and Finland, assigned to receive two oral doses of HRV vaccine versus placebo at 2 and 4 mo of age. Primary outcomes were episodes of gastroenteritis and severity.
Results: 63,225 healthy infants were enrolled. The vaccine was 85% efficacious against severe rotavirus gastroenteritis and hospitalizations associated with gastroenteritis ($p < 0.001$) and 100% efficacious against more severe gastroenteritis. Hospitalization for diarrhea of any cause was reduced by 42% (95% CI 29-53%, $p < 0.001$). Six vaccine recipients and seven placebo recipients had definite intussusception within 31 d after each dose (risk difference -0.32/10,000 infants; 95% CI -2.91 to 2.18, $p = 0.78$).
Conclusion: Two oral doses of the live attenuated HRV vaccine were highly efficacious in decreasing incidence of severe rotavirus and all-cause gastroenteritis, and were not associated with an increased risk of intussusception.

Abnormal Reflex Response

- Absence may suggest CNS abnormality
- Persistence after 4-6 mo may indicate abnormality (e.g. cerebral palsy)
- Asymmetry suggests focal motor lesions (e.g. brachial plexus injury)
- Upgoing plantar reflex (Babinski's sign) normal in infants up to age 2 yr

Developmental Red Flags

- Gross motor: not walking at 18 mo rolling too early at <3 mo
- Fine motor: hand preference at <18 mo
- Speech: <10 words at 18 mo
- Social: not smiling at 3 mo; not pointing at 15-18 mo
- See the Nipissing District Developmental Screen for a checklist of important 18 mo milestones: www.ndds.ca

Table 5. Developmental Milestones (continued)

Age*	Gross Motor	Fine Motor	Speech and Language	Adaptive and Social Skills
15 mo	Walks without support, crawls up stairs/steps	Picks up and eats finger foods, scribbles, stacks 2 blocks	4-5 words, points to needs/wants	Looks to see how others react (e.g. after falling)
18 mo	Runs, walks forward pulling toys or carrying objects	Tower of 3 cubes, scribbling, eats with spoon	10 words, follows simple commands	Shows affection towards others, points to show interest in something
24 mo	Climbs up and down steps with 2 feet per step, runs, kicks ball	Tower of 6 cubes, undresses	2-3 word phrases, uses "I, me, you", 50% intelligible, understands 2-step commands	Parallel play, helps to dress
3 yr	Rides tricycle, climbs up 1 foot per step, down 2 feet per step, stands on one foot briefly	Copies a circle, turns pages one at a time, puts on shoes, dress/undress fully except buttons	Combines 3 or more words into sentence, recognizes colours, prepositions, plurals, counts to 10, 75% intelligible	Knows sex and age, shares some of the time, plays make-believe games
4 yr	Hops on 1 foot, climbs down 1 foot per step	Copies a cross, uses scissors, buttons clothes	Speech 100% intelligible, uses past tense, understands 3-part directions	Cooperative play, fully toilet-trained by day, tries to comfort someone who is upset
5 yr	Skips, rides bicycle	Copies a triangle and square, prints name, ties shoelaces	Fluent speech, future tense, alphabet, retells sequence of a story	Cooperates with adult requests most of the time, separates easily from caregiver

*Use corrected GA until 2 yr

Nutrition

Dietary Requirements

Weight	<10 kg	10-20 kg	>20 kg
Needs	100 kcal/kg/d	1,000 cal + 50 kcal/kg/d for each kg >10	1,500 cal + 20 kcal/kg/d for each kg >20

Dietary Recommendations

- 0-6 mo: breast milk or formula
 - exclusive breast milk during first 6 mo recommended over formula unless contraindicated
 - breastfed infants require supplements: vitamin D (400 IU/d), fluoride (after 6 mo if not sufficient in water), iron (6-12 mo, only if not receiving fortified cereals/meat/meat alternatives)
- >6 mo: solid food introduction – do not delay beyond 9 mo
 - 2-3 new foods per wk, wait at least 2 d in between each food to allow time for adverse reaction identification
 - common allergens: eggs, milk, mustard, peanuts, seafood, sesame, soy, tree nut, wheat
 - early introduction of highly allergenic foods is recommended
 - offer lumpy, soft-cooked, pureed, mashed textured foods
 - 9-24 mo: switch to homogenized (3.25%) milk, offer 16oz/d to non-breast feeding infant
 - offer vegetables, fruit, grains and full-fat milk in any order after iron-rich foods are given
 - provide up to 3 large feedings (meals) with 1-2 smaller feedings (snacks), depending on child's hunger/satiety cues
 - encourage self-feeding and introduce open cup (should be done by 18 mo)
 - foods to avoid
 - honey until past 12 mo (risk of botulism)
 - added sugar, salt
 - excessive milk (i.e. no more than 750 mL or 24 oz/d after 1 yr)
 - limit juice intake (not nutritious, too much sugar), maximum 4-6 oz (1/2 cup) daily anything that is a choking hazard (chunks, round foods like grapes)
 - 2-6 yr: switch to 2% milk (500 mL/day)
 - can maintain breastfeeding during this time complementary to solids

Breastfeeding

- content of breast milk
 - colostrum (first few days): clear, rich in nutrients (i.e. high protein, low fat), immunoglobulin
 - mature milk: 70:30 whey:casein ratio, fat from dietary butterfat, carbohydrate from lactose
- advantages
 - easily digested, low renal solute load
 - immunologic
 - contains IgA, macrophages, active lymphocytes, lysozymes, lactoferrin (which inhibits *E. coli* growth in intestine)
 - lower pH promotes growth of *Lactobacillus* in GI tract

Peanut Allergies in Children

NEJM 2015;372(9):803-813

Study: 640 children identified as "at risk to peanut allergy" due to severe eczema, egg allergy, or both were split into two cohorts depending on their pre-existing sensitivity to peanut extract on skin-prick test. These two cohorts were randomized to peanut consumption or avoidance up until 60 mo of age.

Results: In the cohort with negative skin-prick test at start of study, prevalence of peanut allergy at 60 mo of age was 13.7% in peanut avoidance and 1.9% in the peanut consumption group. In cohort with positive skin-prick test at start of study, prevalence of peanut allergy at 60 mo of age was 35.3% in peanut avoidance and 10.6% in peanut consumption group.

Conclusion: Early introduction of peanuts significantly decreased prevalence of peanut allergies in children deemed "at risk to peanut allergy".

Dietary Exposures and Allergy Prevention in High-Risk Infants

Paediatr Child Health 2013;18(10):545-549

There is no evidence that restriction of highly allergenic foods is beneficial in the first year of life. Later introduction of peanut, fish, or egg does not prevent, and may increase the risk of developing food allergy. There is also no evidence that dietary restrictions during pregnancy or breastfeeding are protective to the child.

- parent-child bonding
- economical, convenient
- maternal contraindications
 - chemotherapy or radioactive compounds
 - HIV/AIDS, active untreated TB, herpes in breast region
 - >0.5 g/kg/d of alcohol or illicit drugs
 - medications known to cross to breast milk
 - OCPs are *not* a contraindication to breastfeeding (estrogen may decrease lactation, but is not dangerous to infant)
 - MotherRisk™ Program – valuable research and counselling on reproductive risk or safety of drugs and chemicals
 - breastfeeding jaundice (first 1-2 wk): due to lack of maternal milk production and subsequent infant dehydration (see *Jaundice*, P69)
 - breast milk jaundice (0.5% of newborns, persists up to 4-6 mo): rare, glucuronyl transferase inhibitor in breast milk inhibits conjugation of bilirubin, increases enterohepatic circulation of bilirubin
 - ♦ baby presents healthy and thriving, and jaundice (secondary to unconjugated bilirubin) resolves
 - poor weight gain: consider dehydration or FTT
 - oral candidiasis (thrush): treat baby with antifungal such as nystatin; can occur in breast or bottle-fed infants

Table 6. Common Formulas Compared to Breast Milk

Type of Nutrition	Indications	Content (as compared to breast milk)
Cow's Milk-Based (Enfamil®, Similac®)	Prematurity Transition into breastfeeding Contraindication to breastfeeding	Lower whey:casein ratio Plant fats instead of dietary butterfat
Fortified Formula	Low birth weight Prematurity	Higher calories and vitamins A, C, D, K May only be used in hospital due to risk of fat-soluble vitamin toxicity
Soy Protein (Isomil®, Prosoabee®)	Galactosemia Desire for vegetarian/vegan diet*	Corn syrup solids or sucrose in place of lactose
Partially Hydrolyzed Proteins (Good Start®)	Delayed gastric emptying Risk of cow milk protein allergy	Protein is 100% whey with no casein
Protein Hydrolysate (Nutramigen®, Alimentum®, Pregestimil®, Portagen®)	Malabsorption Food allergy	Protein is 100% casein with no whey Corn syrup solids, sucrose, or tapioca starch instead of lactose Expensive
Amino Acid (Neocate®, PurAmino™)	Food allergy Short gut	Free amino acids (no protein) Corn syrup solids instead of lactose Very expensive
Metabolic	Inborn errors of metabolism	Various different compositions for children with galactosemia, propionic acidemia, etc.

* 10-35% of children with cow's milk protein allergy also have reactions to soy-based formula

Medications that Cross into Breast Milk

- Antimetabolites
- Bromocriptine
- Chloramphenicol
- High dose diazepam
- Ergots
- Gold
- Metronidazole
- Tetracycline
- Lithium
- Cyclophosphamide

Signs of Inadequate Intake

- < 6 wet diapers/d after first wk
- < 7 feeds/d
- Sleepy or lethargic, sleeping throughout the night < 6 wk
- Weight loss > 10% of birth weight
- Jaundice

- 1 wet diaper per/d of age for first wk
- 1-2 black or dark green stools/d on Day 1 & 2
- 3+ brown/green/yellow stools/d on Day 3 & 4
- 3+ yellow, seedy stools/d on Day 5+

Injury Prevention Counselling

- injuries are the leading cause of death in children >1 yr of age
- main causes: motor vehicle crashes, burns, drowning, falls, choking, infanticide

Table 7. Injury Prevention Counselling

0-6 mo	6-12 mo	1-2 yr	2-5 yr
Do not leave alone on bed, on changing table, or in tub	Install stair barriers	Never leave unattended	Bicycle helmet
Keep crib rails up	Discourage use of walkers	Keep pot handles turned to back of stove	Never leave unsupervised at home, driveway, or pool
Check water temperature before bathing	Avoid play areas with sharp-edged tables and corners	Caution with whole grapes, nuts, raw carrots, hotdogs, etc. due to choking hazard	Teach bike safety, stranger safety, and street safety
Do not hold hot liquid and infant at the same time	Cover electrical outlets	No running while eating	Swimming lessons (> 4 yr), sunscreen (from 6 mo), fences around pools
Check milk temperature before feeding	Unplug appliances when not in use	Appropriate car seats	Appropriate car seats
Appropriate car seats are required before leaving hospital	Keep small objects, plastic bags, cleaning products, and medications out of reach		
	Supervise during feeding		
	Appropriate car seats		

Note: This list is not exhaustive. For more details, see Rourke Baby Record (http://www.rourkebabyrecord.ca/pdf/RRB20110nt_Eng.pdf)

Common Complaints

Breath Holding Spells

- epidemiology: 0.1-5% of healthy children 6 mo-4 yr of age, usually start during first year of life
- etiology: child is provoked (usually by anger, injury, or fear) → holds breath and becomes silent → spontaneously resolves or loses consciousness
- types
 - cyanotic (more common), usually associated with anger/frustration
 - pallid, usually associated with pain/surprise
- management
 - usually resolves spontaneously and rarely progresses to seizure
 - help child control response to frustration and avoid drawing attention to spell
 - may be associated with iron deficiency anemia, improves with supplemental iron

Circumcision

- elective procedure
 - not covered by OHIP in Ontario, but recent evidence shows risks vs. benefit → not clearly different; no clear position by CPS in 2015 statement
 - often for religious or culture reasons
- benefits: prevention of phimosis and slightly reduced incidence of UTI, STI, balanitis, cancer of the penis
- complications (<1%): local infection, bleeding, urethral injury
- contraindications: presence of genital abnormalities (e.g. hypospadias) or known bleeding disorder

Crying/Fussing Child

- history
 - description of baseline feeding, sleeping, crying patterns
 - infectious symptoms: fever, tachypnea, rhinorrhea, ill contacts
 - feeding intolerance: gastroesophageal reflux with esophagitis, N/V, diarrhea, constipation
 - trauma
 - recent immunizations (vaccine reaction) or medications (drug reactions), including maternal drugs taken during pregnancy (neonatal withdrawal syndrome) and drugs that may be transferred via breast milk
 - inconsistent history, pattern of numerous emergency department visits, high-risk social situations all raise concern of maltreatment

Newborn Male Circumcision

Pediatr Child Health 2015;20(6):311-20
Canadian Paediatric Society and the American Academy of Pediatrics have both previously indicated that circumcision of newborn males is not a medically indicated procedure. Some evidence has subsequently suggested decreased urinary tract infections and incidence of some sexually transmitted infections, including HIV, with circumcision. While such a benefit may be present in some boys and high-risk populations where the procedure may be considered in the context of reduction or treatment, the Canadian Paediatric Society continues to not recommend routine circumcision for every newborn male.

Table 8. Physical Exam and Differential Diagnosis

Organ System	Possible Examination Findings	Possible Diagnosis
HEENT	Bulging fontanelle, bulging and erythematous TM Blepharospasm, tearing Retinal hemorrhage Oropharyngeal infections	Meningitis, shaken baby syndrome, hydrocephalus Corneal abrasion, glaucoma Shaken baby syndrome Thrush, gingivostomatitis, herpangina, otitis media
Neurological	Irritability or lethargy	Meningitis, shaken baby syndrome
Cardiovascular	Poor perfusion Tachycardia	Sepsis, anomalous coronary artery, meningitis, myocarditis, CHF
Respiratory	Tachypnea Grunting	Pneumonia, CHF Respiratory disease, response to pain
Abdominal	Mass, empty RLQ	Intussusception
Genitourinary	Scrotal swelling Penile/clitoral swelling	Incarcerated hernia, testicular torsion Hair tourniquet
Rectal	Anal fissure Hemoccult positive stool	Constipation or diarrhea Intussusception, NEC, volvulus
Musculoskeletal	Point tenderness or decreased movement	Fracture, syphilis, osteomyelitis, toe/finger hair tourniquet

Infantile Colic

- **definition:** unexplained paroxysms of irritability and crying for >3 h/d, >3 d/wk for >3 wk in an otherwise healthy, well-fed baby (rule of 3s)
- **epidemiology:** 10% of infants; usual onset 10 d to 3 mo of age with peak at 6-8 wk
- **etiology:** unknown. Theories: alterations in fecal microflora, cow's milk intolerance, GI immaturity or inflammation, poor feeding, maternal smoking

- diagnosis of exclusion: rule out otitis media, cow's milk intolerance, GI problem, fracture
- **management**
 - parental relief, rest, and reassurance
 - hold baby, soother, car ride, music, vacuum, check diaper
 - some evidence for probiotics
 - maintain breastfeeding but eliminate allergens (cow's milk protein, eggs, wheat and nuts) from mother's diet
 - try casein hydrolysate formula (Nutramigen®)
 - time – all resolve, most in the first 3-6 mo of life, no long-term adverse effects

Dentition and Caries

Dentition

- primary dentition (20 teeth)
 - first tooth at 5-9 mo (lower incisor), then 1/mo
 - 6-8 central teeth by 1 yr
 - assessment by dentist 6 mo after eruption of first tooth and certainly by 1 yr of age (Grade B recommendation)
- secondary dentition (32 teeth)
 - first adult tooth is 1st molar at 6 yr, then lower incisors

Caries

- milk caries: decay of superior front teeth and back molars in first 4 yr of life
- cause: often due to prolonged feeding (e.g. put to bed with bottle, prolonged breastfeeding)
- prevention
 - no bottle at bedtime, clean teeth after last feed
 - minimize juice and sweetened pacifier
 - clean teeth with soft damp cloth or toothbrush and water
 - water fluoridation

Enuresis

Definition

- involuntary urinary incontinence by day and/or night in child >5 yr

General Approach

- should be evaluated if dysuria, change in colour, odour, stream, secondary or diurnal, change in gait, stool incontinence

Primary Nocturnal Enuresis

- **definition:** involuntary loss of urine at night, bladder control has never been attained
- **epidemiology:** boys > girls; 10% of 6 yr olds, 3% of 12 yr olds, 1% of 18 yr olds
- **etiology:** developmental disorder or maturational lag in bladder control while asleep
- **management**
 - time and reassurance (~20% resolve spontaneously each yr)
 - behaviour modification (limiting fluids, voiding prior to sleep), bladder retention exercises, scheduled toileting overnight has limited effectiveness
 - conditioning: "wet" alarm wakes child upon voiding (70% success rate)
 - medications (for children >7 yr, considered second line therapy, may be used for sleepovers/camp): DDAVP oral tablets (similar success rate as "wet" alarm therapy but higher relapse rate), imipramine (Tofranil®) (rarely used, lethal if overdose, SE: cardiac toxicity, anticholinergic effects)

Secondary Enuresis

- **definition:** involuntary loss of urine at night, develops after child has sustained period of bladder control (>6 mo)
- **etiology:** inorganic regression due to stress or anxiety (e.g. birth of sibling, significant loss, family discord, sexual abuse), secondary to organic disease (UTI, DM, DI, sleep apnea, neurogenic bladder, CP, seizures, pinworms)
- **management:** treat underlying cause

Diurnal Enuresis

- **definition:** daytime wetting (60-80% also wet at night)
- **etiology:** micturition deferral (holding urine until last minute) due to psychosocial stressor (e.g. shy), structural anomalies (e.g. ectopic ureteral site, neurogenic bladder), UTI, constipation, CNS disorders, DM
- **management:** treat underlying cause, behavioural (scheduled toileting, double voiding, good bowel program, sitting backwards on toilet, charting/incentive system, relaxation/biofeedback), pharmacotherapy

Treatment for primary nocturnal enuresis should not be considered until 7 yr of age due to high rate of spontaneous cure

Antidiuretic Hormone Regulation in Primary Nocturnal Enuresis

Arch Dis Child 1995;73(6):508-11

Purpose: To evaluate the efficacy of DDAVP for the treatment of primary nocturnal enuresis.

Methods: Children with primary nocturnal enuresis were compared with a corresponding control group. Diurnal and nocturnal urine production, ADH secretion, and plasma osmolality were determined.

Results: Ten children (mean age 10.5 years) with primary nocturnal enuresis were compared to a control group of eight patients. No differences in urine production, ADH levels during day and night, or plasma osmolality were found. However, the enuretic children required a markedly greater ADH output (2.87 pg/ml/mmol/kg vs. 0.56 in controls; $p < 0.01$).

Conclusion: ADH secretion is a function of plasma osmolality. Urine production is not increased at night in individuals with primary nocturnal enuresis because of lower ADH secretion.

Encopresis

- **definition:** fecal incontinence in a child >4 yr old, at least once per mo for 3 mo
- **prevalence:** 1-1.5% of school-aged children (rare in adolescence); M:F = 6:1 in school-aged children
- **causes:** chronic constipation (retentive encopresis), Hirschsprung disease, hypothyroidism, hypercalcemia, spinal cord lesions, anorectal malformations, bowel obstruction

Retentive Encopresis

- **definition:** child holds bowel movement, develops constipation, leading to fecal impaction and seepage of soft or liquid stool (overflow incontinence)
- **etiology**
 - physical: painful stooling often secondary to constipation
 - emotional: disturbed parent-child relationship, coercive toilet training, social stressors
- **clinical presentation**
 - history
 - ◆ crosses legs or stands on toes to resist urge to defecate
 - ◆ distressed by symptoms, soiling of clothes
 - ◆ toilet training coercive or lacking in motivation
 - ◆ may show oppositional behaviour
 - ◆ abdominal pain
 - physical exam
 - ◆ digital rectal exam or abdo x-ray: large fecal mass in rectal vault
 - ◆ anal fissures (result from passage of hard stools)
 - palpable stool in LLQ
- **management**
 - complete clean-out of bowel: PEG 3350 given orally is most effective, enemas and suppositories may be second line therapies, but these are invasive and often less effective
 - maintenance of regular bowel movements (see *Constipation Treatment, P36*)
 - assessment and guidance regarding psychosocial stressors
 - behavioural modification
- **complications:** recurrence, toxic megacolon (requires >3-12 mo to treat), bowel perforation

Toilet Training

- 90% of children attain bladder control before bowel control
- generally, females train earlier than males
- 25% by 2 yr (in North America), 98% by 3 yr have daytime bladder control
- signs of toilet readiness
 - ambulating independently, stable on potty, desire to be independent or to please caregivers (i.e. motivation), sufficient expressive and receptive language skills (2-step command level), can stay dry for several h (large enough bladder), can recognize need to go, able to remove clothing

Failure to Thrive

- **definition**
 - weight <3rd percentile, falls across two major percentile curves, or <80% of expected weight for height and age
 - inadequate caloric intake most common factor in poor weight gain
 - may have other nutritional deficiencies (e.g. protein, iron, vitamin D)
 - factors affecting physical growth: genetics, intrauterine factors, nutrition, endocrine hormones, chronic infections/diseases, psychosocial factors
- **clinical presentation**
 - history
 - ◆ nutritional intake
 - ◆ current symptoms
 - ◆ past illnesses
 - ◆ family history: growth, puberty, parental height and weight including mid-parental height
 - ◆ psychosocial history
 - physical exam
 - ◆ growth parameters, plotted: height, weight, head circumference, arm span
 - ◆ vital signs
 - ◆ complete head to toe exam
 - ◆ dysmorphic features or evidence of chronic disease
 - ◆ upper to lower segment ratio
 - ◆ sexual maturity staging
 - ◆ signs of maltreatment or neglect
- **investigations** (as indicated by clinical presentation)
 - ◆ CBC, blood smear, electrolytes, T4, TSH
 - ◆ bone age x-ray
 - ◆ chromosomes/karyotype
 - ◆ chronic illness: chest (CXR, sweat Cl⁻), cardiac (CXR, ECG, Echo), GI (celiac screen, inflammatory markers, malabsorption), renal (urinalysis), liver (enzymes, albumin)

Mid-Parental Height

- Boys target height = (father ht + mother ht + 13) / 2
- Girls target height = (father ht + mother ht - 13) / 2

Note: height should be taken in cm

Clinical Signs of FTT

SMALL KID
 Subcutaneous fat loss
 Muscle atrophy
 Alopecia
 Lethargy
 Lagging behind normal
 Kwashiorkor
 Infection (recurrent)
 Dermatitis

Table 9. Failure to Thrive Patterns

Growth Parameters			Suggestive Abnormality	
Decreased Wt	Normal Ht	Normal HC	Caloric insufficiency Decreased intake	Hypermetabolic state Increased losses
Decreased Wt	Decreased Ht	Normal HC	Structural dystrophies Endocrine disorder	Constitutional growth delay (BA < CA) Familial short stature (BA = CA)
Decreased Wt	Decreased Ht	Decreased HC	Intrauterine insult	Genetic abnormality

BA = bone age; CA = chronological age; HC = head circumference; Ht = height; Wt = weight

Etiology

- an interplay between pathophysiology and psychosocial influences. Investigations should assess:
 - complex factors in the parent-child relationship
 - dietary intake, knowledge about feeding, improper mixing of formula
 - feeding environment
 - parent-child interaction, attachment
 - child behaviours, hunger/satiety cues
 - postpartum depression
 - social factors: stress, poverty, neglect, child/domestic abuse, parental substance abuse, restricted diets
 - inadequate caloric intake: inadequate milk supply/latching, mechanical feeding difficulty (cleft palate), oromotor dysfunction, toxin-induced anorexia
 - inadequate absorption: biliary atresia, celiac, IBD, CF, inborn errors of metabolism, milk protein allergy, pancreatic cholestatic conditions
 - increased metabolism: chronic infection, CF, lung disease from prematurity, hyperthyroidism, asthma, IBD, malignancy, renal failure

Management

- most as outpatient using multidisciplinary approach: primary care physician, dietitian, psychologist, social work, CAS
- medical: oromotor problems, iron-deficiency anemia, gastro-esophageal reflux
- nutritional: educate about age-appropriate foods, calorie boosting, mealtime schedules and environment; goal to reach 90-110% IBW, correct nutritional deficiencies, and promote catch-up growth/development
- behavioural: positive reinforcement, mealtime environment

Energy Requirements

- see *Nutrition, P6*

Obesity

- definition:** overweight is BMI >85th percentile; obesity is BMI >95th percentile for age and height
- risk factors:** genetic predisposition (e.g. both parents obese – 80% chance of obese child)
- etiology:** organic causes are rare (<5%), but may include Prader-Willi, Carpenter, Turner, Cushing syndromes, hypothyroidism
- complications:** association with HTN, dyslipidemia, slipped capital femoral epiphysis, type 2 DM, asthma, obstructive sleep apnea, gynecomastia, polycystic ovarian disease, early menarche, irregular menses, psychological trauma (e.g. bullying, decreased self-esteem, unhealthy coping mechanisms, depression)
- childhood obesity often persists into adulthood
- investigations:** BP, pulse, screen lipid profile
- management**
 - encouragement and reassurance; engagement of entire family
 - diet: qualitative changes (do not encourage weight loss, but allow for linear growth to catch up with weight), special diets used by adults and very low calorie diets are not encouraged
 - behaviour modification: increase activity, change eating habits/meal patterns, limit juice/sugary drinks, ensure adequate sleep
 - education: multidisciplinary approach, dietitian, counselling
 - surgery and pharmacotherapy are rarely used in children
 - increase physical activity (1 h/d), reduce screen time (< 2 h/d)
 - in children with risk factors/complications: AST/ALT and diabetes screening, small changes in energy expenditure and intake (lose 1 lb/mo)
 - long term goal: maintain BMI <85th percentile

Poison Prevention

- keep all types of medicines, vitamins, and chemicals locked up in a secure container
- potentially dangerous: medications, illicit drugs, drain cleaners, furniture polish, insecticides, cosmetics, nail polish remover, automotive products
- do not store any chemicals in juice, soft drink, or water bottles
- keep alcoholic beverages out of reach: 3 oz hard liquor can kill a 2 yr old
- always read labels before administering medicine to ensure correct medication drug and dose and/or speak with a pharmacist or healthcare provider

Upper to Lower Segment Ratio

- Increased** in achondroplasia, short limb syndromes, hypothyroid, storage diseases
- Decreased** in Marfan's, Klinefelter's, Kallman's syndromes, and testosterone deficiency
- Calculation:** upper segment/lower segment
 - Upper segment: top of head to pubic symphysis
 - Lower segment: pubic symphysis to floor

Perinatal and Early Childhood Factors for Overweight and Obesity in Young Canadian Children

Can J Public Health 2013;104(1):e69-74

Purpose: To assess potential early-life factors and their interrelationships with obesity among young Canadian children.

Methods: Data from a nationally representative sample of children aged 6-11 yr in the Canadian Health Measures Survey were analyzed. The associations of perinatal and early childhood behaviours and socioeconomic factors with overweight or obesity were evaluated using multivariate logistic regression models.

Results: Of 968 term-born children, 21% were overweight and another 13% were obese. Maternal smoking during pregnancy was positively associated with obesity. This association was mediated by birth weight and once controlled, the strength of the association between smoking and child obesity increased by 12%. Birth weight per 100 g (1.05; 1.005-1.09) was significantly associated with obesity. Exclusive breastfeeding for 6 mo, adequate sleep hours, and being physically active were found to be protective. Breastfeeding, whether exclusive or not, significantly reduced obesity risk among children whose mothers never smoked in pregnancy.

Conclusion: This study identified multiple perinatal and childhood factors associated with obesity in young Canadian children. Effective prevention strategies targeting four modifiable maternal and child risk factors may reduce childhood obesity by up to 54% in Canada.

Screen Time Guidelines (Canadian Society for Exercise Physiology)

- Screen time is not recommended for children under 2 yr
- <1 h/d screen time is appropriate for children aged 2-5 yr
- <2 h/d screen time is appropriate for children 5-17 yr

Rashes

Table 10. Common Pediatric Rashes

Type of Rash	Differential	Appearance	Management
Diaper Dermatitis	Irritant contact dermatitis	Shiny, red macules/patches, no skin fold involvement	Eliminate direct skin contact with urine and feces, allow periods of rest without a diaper, frequent diaper changes, topical barriers (petrolatum, zinc oxide or paste), short-term low-potency topical corticosteroids (severe cases)
	Seborrheic dermatitis	Yellow, greasy macules/plaques on erythema, scales	Short-term, moisturisers, topical antifungal (ketoconazole), low-potency topical corticosteroids
	Candidal dermatitis	Erythematous macerated papules/plaques, satellite lesions, involvement of skin folds	Antifungal agents (e.g. clotrimazole, nystatin)
Other Dermatitis	Atopic dermatitis	Erythematous, papules/plaques, oozing, excoriation, lichenification, classic areas of involvement	Eliminate exacerbating factors, maintain skin hydration (daily baths and moisturisers), corticosteroids, topical calcineurin inhibitor (2nd line)
	Nummular dermatitis	Annular erythematous plaques, oozing, crusting	Avoid irritant if identified, potent topical steroid in emollient base, short-term systemic steroids ± antibiotics (severe)
	Allergic contact dermatitis	Red papules/plaques/vesicles/bullae, only in area of allergen	Mild: soothing lotion (e.g. calamine lotion) Moderate: low-to-intermediate potency topical corticosteroids Severe: systemic corticosteroids and antihistamine
	Irritant contact dermatitis	Morphology depends on irritant	Avoid skin contact
	Dyshidrotic dermatitis	Papulovesicular, cracking/fissuring, hands and feet ("tapioca pudding")	Mild/moderate: medium/potent topical corticosteroids Severe: systemic corticosteroids, local PUVA or UVA treatments
Infectious	Scabies	Polymorphic (red excoriated papules/nodules, burrows), in web spaces/folds, very pruritic. Often affects multiple family members	Permethrin (Nix®) 5% cream for patient and family (2 applications, 1 wk apart)
	Impetigo	Honey-coloured crusts or superficial bullae	Topical antibiotics if mild: fucidic acid or mupirocin cream; Oral antibiotics if severe (e.g. cephalixin/erythromycin)
	Tinea corporis	Round erythematous plaques, central clearing and scaly border	Topical anti-fungal for skin, systemic anti-fungals for nails/head

Pediatric Exanthems (see *Infectious Pediatric Exanthems, P50*)

Drug Reactions (see *Dermatology, D21*)

Acne (see *Dermatology, D11*)

Sleep Disturbances

Types of Sleep Disturbances

- insufficient sleep quantity
 - difficulty falling asleep (e.g. limit setting sleep disorder)
 - preschool and older children
 - bedtime resistance
 - due to caregiver's inability to set consistent bedtime rules and routines
 - often exacerbated by child's oppositional behaviours
- poor sleep quality
 - frequent arousals (e.g. sleep-onset association disorder)
 - infants and toddlers
 - child learns to fall asleep only under certain conditions or associations (e.g. with parent, held, rocked or fed, with light on, in front of television), and loses ability to self-soothe
 - during the normal brief arousal periods of sleep (q90-120 min), child cannot fall back asleep because same conditions are not present
 - obstructive sleep apnea
 - epidemiology: 1-5% of preschool aged children, more common in African American children
 - definition: partial or intermittent complete airway obstruction during sleep causing disrupted ventilation and sleep pattern
 - features: snoring/gasping/noisy breathing during sleep and irritable/tired/hyperactive during the day
 - sequelae: cardiovascular (HTN/LV remodelling due to sympathetic activation), growth, cognitive, and behavioural deficits

Daily Sleep Requirement

- < 6 mo 16 h
- 6 mo 14.5 h
- 12 mo 13.5 h
- 2 yr 13 h
- 4 yr 11.5 h
- 6 yr 9.5 h
- 12 yr 8.5 h
- 18 yr 8 h

Nap Patterns

- 2/d at 1 yr
- 1/d at 2 yr: 2-3 h
- 0.5/d at 5 yr: 1.7 h

- risk factors: adenotonsillar hypertrophy, craniofacial abnormalities, obesity
- investigation: polysomnography is gold standard for diagnosis but not required (expensive, inaccessible)
- management: adenotonsillectomy and weight management are first-line tx, follow-up for residual OSA. Watchful waiting acceptable in mild-moderate cases
 - ◆ adenotonsillectomy does not improve executive function/attention but improves behaviour, QOL, polysomnographic findings
 - ◆ use CPAP if adenotonsillectomy is contraindicated (cleft palate/bleeding disorder/acute tonsillitis), OSA w/ minimal adenotonsillar tissue, residual OSA
 - ◆ avoid pollutants/tobacco smoke, allergens
 - ◆ avoid use of corticosteroids and antibiotics
- parasomnias
 - episodic nocturnal behaviours (e.g. sleepwalking, sleep terrors, nightmares)
 - often involves cognitive disorientation and autonomic/skeletal muscle disturbance

Management of Sleep Disturbances

- set strict bedtimes and “wind-down” routines
- do not send child to bed hungry
- positive reinforcement for: limit setting sleep disorder
- always sleep in own bed, in a dark, quiet, and comfortable room
- do not use bedroom for timeouts
- systematic ignoring and gradual extinction for: sleep-onset association disorder

Nightmares

- **epidemiology:** common in boys, 4-7 yr old
- associated with REM sleep (anytime during night)
- **features:** upon awakening, child is alert and clearly recalls frightening dream ± associated with daytime stress/anxiety
- **management:** reassurance

Night Terrors

- **epidemiology:** 15% of children have occasional episodes
- abrupt sitting up, eyes open, screaming
- **clinical features:** occurs in early hours of sleep, stage 4 of sleep; signs of panic and autonomic arousal, no memory of event, inconsolable, stress/anxiety can aggravate them
- **course:** remits spontaneously at puberty
- **management:** reassurance for parents, ensure child is safe (e.g. if sleepwalks)

Sudden Infant Death Syndrome

Definition

- sudden and unexpected death of an infant <12 mo of age in which the cause of death cannot be found by history, examination, or a thorough postmortem and death scene investigation

Epidemiology

- 0.5/1,000 (leading cause of death between 1-12 mo of age); M:F = 3:2
- more common in children placed in prone position
- in full term infants, peak incidence is 2-4 mo, 95% of cases occur by 6 mo
- increase in deaths during peak RSV season
- most deaths occur between midnight and 8 AM

Risk Factors

- prematurity (<37 wk), early bed sharing (<12 wk), alcohol use during pregnancy, soft bedding, low birthweight, bed sharing, Aboriginals ethnicity, male, no prenatal care, smoking in household, prone sleep position, poverty
- risk of SIDS is increased 3-5x in siblings of infants who have died of SIDS
- bedsharing: sleeping on a sofa, sleeping with an infant after consumption of alcohol/street drugs or extreme fatigue, sleeping on a surface with a fixed wall (couch/sofa), infant sleeping with someone other than primary caregiver

Prevention

- “Back to Sleep, Front to Play” (place infant on back when sleeping)
- avoid sharing bed with infant
- allow supervised play time daily in prone position (“tummy time”)
- alarms, monitors not recommended – increase anxiety, do not prevent life-threatening events
- avoid overheating and overdressing
- appropriate infant bedding (firm mattress, avoid loose bedding, pillows, stuffed animals, and crib bumper pads)
- no smoking
- exclusive breastfeeding in first mo
- pacifiers appear to have a protective effect; do not reinsert if falls out during sleep
- infant monitors do not reduce incidence

Brief Resolved Unexplained Events (BRUE)

A group of conditions often marked by an episode of apnea, cyanosis, change in tone, or change in mental status occurring in a child, where an observer fears the child may be dying. There is no clear connection between most BRUEs and SIDS. Evaluating for a cause of the BRUE (e.g. infection, cardiac, neurologic) is guided by history, physical exam, and period of observation

Child Abuse and Neglect

Definition

- an act of commission (physical, sexual, or psychological abuse) or omission (neglect) by a caregiver that harms a child

Legal Duty to Report

- upon reasonable grounds to suspect abuse and/or neglect, physicians are required by legislation to contact the CAS to personally disclose all information relevant to the child safety concern
- duty to report overrides patient confidentiality; physician is protected against liability

Ongoing Duty to Report

- if there are additional reasonable grounds to suspect abuse and/or neglect, a further report to the CAS must be made

Risk Factors

- environmental factors: social isolation, poverty, domestic violence
- caregiver factors: personal history of abuse, psychiatric illness, postpartum depression, substance abuse, single parent family, poor social and vocational skills, below average intelligence
- child factors: difficult temperament, disability, special needs (e.g. developmental delay), premature

Management of Physical Abuse, Child Abuse, and Neglect

- report all suspicions to CAS; request emergency visit if imminent risk to child or any siblings in the home
- acute medical care: hospitalize for medical evaluation or treatment of injuries if indicated
- arrange consultation to social work and appropriate follow-up
- may need to discharge child directly to CAS or to responsible guardian under CAS supervision

Physical Abuse

History

- history that is not compatible with physical findings or with child's developmental capabilities
- history not reproducible or changes dramatically over time
- delay in seeking medical attention that is unexplained by other factors
- assess previous trauma or hospitalizations
- ask FHx: bleeding disorder, bone disorder, metabolic conditions
- ask developmental history

Physical Exam

- physical findings not explained by underlying medical condition
- growth parameters including past recorded parameters (weight, height, head circumference)
- multiple injuries not explained by accidental injury or child's development level
- patterned skin injuries: belt buckle, hand prints, burns that do not match provided history
- injury location: bruises: on areas with abundant soft-tissue cushioning, such as abdomen, buttocks, genitalia, fleshy part of cheek or on ears, neck or feet; fractures: posterior rib/metaphyseal/scapular/vertebral/sternal fractures (more suspicious for non-accidental injuries); bruises that do not fit described cause; immersion burns (e.g. hot water)
- altered mental status: head injury, poisoning
- eyes – retinal hemorrhages
- scalp – patchy hair loss from traumatic alopecia or severe malnutrition
- oral exam – check the frenula for tears
- head trauma is the leading cause of death in child maltreatment (e.g. acceleration-deceleration forces [shaking], direct force application [blow or impact])
- consider “red herrings” (e.g. slate grey macule/congenital dermal melanocytosis vs. bruises)

Investigations

- document all injuries on a body diagram: type, location, size, shape, colour, pattern
 - photography of skin injuries is ideal (police or hospital photography preferred; do not use physician's personal camera)
- rule out medical causes of bruising/fracture with appropriate investigations (e.g. blood disorders or rickets):
 - if fractures evident: Ca^{2+} , Mg^{2+} , PO_4^{3-} , ALP, PTH, Vitamin D, albumin
 - if bruising present: CBC, INR, PTT, von Willebrand factor, factors VIII/IX/
- screen for abdominal trauma
 - transaminases and amylase if elevated: abdo CT recommended
 - renal function – electrolytes, urinalysis
 - toxicology screen – overdose or poisoning
- skeletal survey in children <2 yr; select imaging based on history in children >5 yr
 - neuroimaging: CT and/or MRI - dilated eye examination by pediatric ophthalmologist to rule out retinal haemorrhage if subdural hemorrhage detected on head imaging

Medical Assessment of Bruising in Suspected Child Maltreatment Cases

Paediatr Child Health 2013;18(8):433-7

CPS Position Statement: While bruises are most often due to minor accidental injury, they may also signal underlying medical illness or inflicted injury. Knowing when to assess bruises in the context of maltreatment can be challenging. The following are red flags for inflicted injury in such bruising cases:

- Babies not yet cruising
- Present on ears, neck, feet, buttocks or torso
- Not on the front of the body and/or overlying bone
- Unusually large or numerous
- Clustered or patterned
- Not fitting with the described causal mechanism

Sexual Abuse

Epidemiology

- peak ages at 2-6 yr and 12-16 yr, most do not report until adulthood
- as adults: more likely to develop obesity, sexual problems, IBS, fibromyalgia, STI, substance use disorder. More likely to experience intimate partner violence and sexual assault
- in decreasing order: family member, non-relative known to victim, stranger

History

- do not take a sexual abuse history from a young child; this must be done by trained personnel (e.g. during a forensic interview)
- psychosocial: specific or generalized fears, depression, nightmares, social withdrawal, lack of trust, low self-esteem, school failure, sexually aggressive behaviour, advanced sexual knowledge, sexual preoccupation or play

Physical Exam

- recurrent UTIs, pregnancy, STIs, vaginitis, vaginal bleeding, pain, genital injury, enuresis
 - anogenital exam performed along with head-to-toe physical for physical trauma
 - instrumentation not required for anogenital exam, speculum contraindicated in prepubertal girls
 - most victims have normal anogenital exam – cannot rule out sexual abuse if exam is negative

Investigations

- depend on presentation, age, sex, and pubertal development of child
 - sexual assault examination kit within 24 h if prepubertal, within 72 h if pubertal
 - rule out STI, UTI, pregnancy (consider STI prophylaxis or emergency contraception)
 - rule out other injuries (vaginal/anal/oral penetration, fractures, head trauma)
 - investigations to rule out drug and alcohol screen e.g. Rohypnol, 'Liquid G', etc.

Neglect

Definition

- omissions in care by parents or caregiver that leads in actual or potential harm

History

- from child and each caregiver separately (if possible)

Physical Exam

- head to toe (do not force), growth parameters, nutrition status
- dental care
- emotional state

Investigations

- blood tests to rule out medical conditions (e.g. thrombocytopenia or coagulopathy)

Adolescent Medicine

Adolescent History (HEADSSS)

- tailor your history according to the clinical context

Home: Who do you live with? What kind of place do you live in? Do you get along with your parents and/or siblings?

Education/Employment: What grade are you in? What are your favourite subjects? What was your average on your last report card (ask for changes)? How much school have you missed this past year? Do you work (if so, how much)? Do you get along with teachers/employers?

Eating: Tell me about your meals/snacks in a typical day. Have you ever gone on a diet? What are your favourite and least favourite foods? (see [Psychiatry, Eating Disorders, PS30](#))

Activities: What do you do after school? On the weekends? How much time do you spend on the computer/watching TV every day? Do you use social media (i.e. Facebook, Twitter, Instagram, etc.)? What do you do with your friends outside of school?

Drugs: Which seems to be more popular at your school, alcohol or drugs? How often do you drink/smoke marijuana/take other drugs? Do you smoke cigarettes? When you drink, do you usually get drunk? Have you ever passed out or not been able to remember what happened while you were drinking? Has anything bad ever happened to you while you were drunk or stoned? (see [Psychiatry, Substance Abuse, PS21](#))

Presentation of Neglect

- FTT, developmental delay
- Inadequate or dirty clothing, poor hygiene
- Child exhibits poor attachment to parents, no stranger anxiety

Adolescent Psychosocial Assessment

HEADSSS

- Home
- Education/Employment
- Eating
- Activities
- Drugs
- Sexuality
- Suicide and depression
- Safety/violence

Rates of drug use in high school students who have used in the past year: alcohol (58.2%), cannabis (25.6%), tobacco (11.7%)

Date rape comprises 80% of sexual assault in teenagers

Sexuality: Are you romantically interested in anyone? When you think about having sex with someone, do you think about females, males, or both? Have you ever had sex with anyone? Whether the answer is yes or no, the next question is: What activities would you include in the term 'having sex'? What do you do to prevent getting a STI/getting pregnant/getting someone pregnant? Has anyone ever given you money, drugs, or other stuff in exchange for sex? (see *Gynecology, Sexually Transmitted Infections, GY27*)

Suicidality/Depression: On a scale of 1 to 10, where 1 is so sad that you might kill yourself and 10 is the happiest you could be, where are you most days? Have you lost interest in activities that you used to enjoy? Do you often have trouble sleeping (Is there a difference between school days and the weekend)? Have you ever thought seriously about suicide? Did you make a plan? (see *Psychiatry, Depression/Suicide, PS10, PS4*)

Safety/Violence: Do you ever get into a car with a driver who has been drinking? Do you always wear a seatbelt/bicycle helmet? Are you being bullied at school? Has anyone ever touched you in an unwanted way?

See *Normal and Abnormal Pubertal Development, P30*

Prevalence of depression: 1-2% in pre-pubertal children and 6-8% in adolescents

Cardiology

Congenital Heart Disease

PRENATAL CIRCULATION

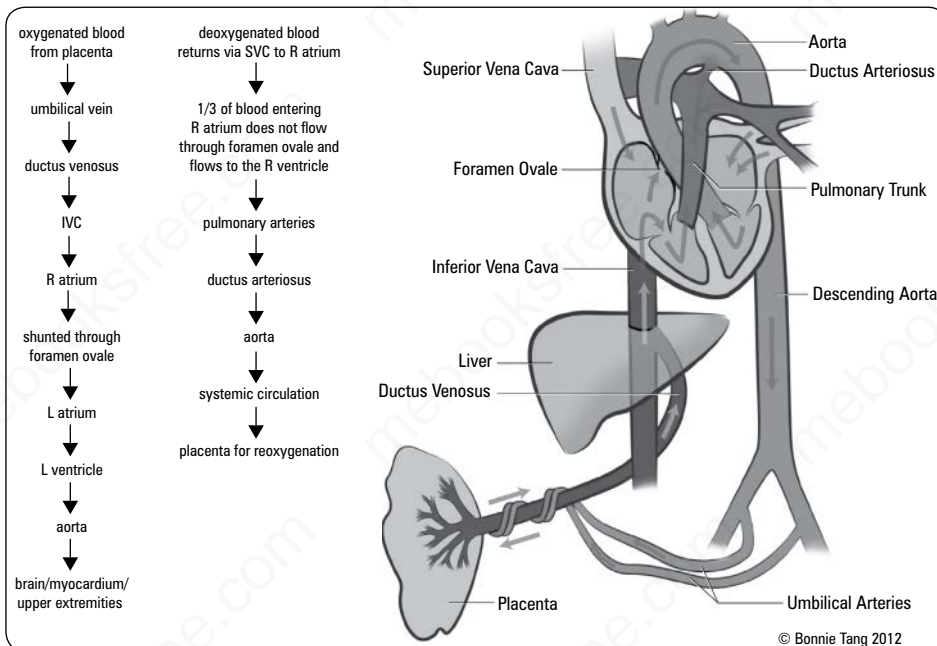

Figure 1. Prenatal circulation

Before Birth

- shunting deoxygenated blood
 - ductus arteriosus: connection between pulmonary artery and aorta
- shunting oxygenated blood
 - foramen ovale: connection between right and left atria
 - ductus venosus: connection between umbilical vein and inferior vena cava

At Birth

- with first breath, lungs open up → pulmonary resistance decreases → pulmonary blood flow increases
- separation of low resistance placenta → systemic circulation becomes a high resistance system → ductus venosus closure
- increased pulmonary flow → increased left atrial pressures → foramen ovale closure
- increased oxygen concentration in blood after first breath → decreased prostaglandins → ductus arteriosus closure
- closure of fetal shunts and changes in vascular resistance → infant circulation assumes normal adult flow

Epidemiology

- 8/1,000 live births have CHD, which may present as a heart murmur, heart failure, or cyanosis; VSD is the most common lesion

Fetal circulation is designed so that oxygenated blood is preferentially delivered to the brain and myocardium

Investigations

- Echo, ECG, CXR
- pre and postductal oxygen saturations, 4 limb BPs, hyperoxia test

CYANOTIC VS. ACYANOTIC CONGENITAL HEART DISEASE

- cyanosis: blue mucous membranes, nail beds, and skin secondary to an absolute concentration of deoxygenated hemoglobin of at least 30 g/dL
- acyanotic heart disease (i.e. L to R shunt, obstruction occurring beyond lungs): blood passes through pulmonary circulation → oxygenation takes place → low levels of deoxygenated blood in systemic circulation → no cyanosis
- cyanotic heart disease (i.e. R to L shunt): blood bypasses the lungs → no oxygenation occurs → high levels of deoxygenated hemoglobin enters the systemic circulation → cyanosis

Figure 2. Common congenital heart diseases

Characteristic CXR Findings in CHD

- Boot-shaped heart: tetralogy of Fallot, tricuspid atresia
- Egg-shaped heart: transposition of great arteries
- "Snowman" heart: total anomalous pulmonary venous return

Acyanotic Congenital Heart Disease

1. LEFT-TO-RIGHT SHUNT LESIONS

- extra blood is displaced through a communication from the left to the right side of the heart → increased pulmonary blood flow → increased pulmonary pressures
- shunt volume is dependent upon three factors: (1) size of defect, (2) pressure gradient between chambers or vessels, and (3) peripheral outflow resistance
- untreated shunts can result in pulmonary vascular disease, left ventricular dilatation and dysfunction, right ventricular HTN and RVH, and ultimately R to L shunts

Atrial Septal Defect

- 3 types: *ostium primum* (common in DS), *ostium secundum* (most common type, 50-70%), *sinus venosus* (defect located at entry of superior vena cava into right atrium)
- **epidemiology:** 6-8% of congenital heart lesions, common in patients with certain congenital disorders (e.g. Down's syndrome, fetal alcohol syndrome)
- **natural history**
 - 80-100% spontaneous closure rate if ASD diameter <8 mm
 - if remains patent, CHF and pulmonary HTN can develop in adult life
- **clinical presentation**
 - history: often asymptomatic in childhood
 - physical exam: grade 2-3/6 pulmonic outflow murmur, widely split and fixed S2
 - children with large ASDs may have signs of heart failure (tachypnea, FTT, hepatomegaly, pulmonary rales/retractions)
- **investigations**
 - ECG: RAD, mild RVH, RBBB
 - CXR: increased pulmonary vasculature, cardiac enlargement
 - Echo: test of choice
- **management:** elective surgical or catheter closure between 2-5 yr of age

Ventricular Septal Defect

- most common congenital heart defect (30-50%)
- small VSD (majority)
 - **clinical presentation**
 - ♦ history: asymptomatic, normal growth and development
 - ♦ physical exam: early systolic to holosystolic murmur, best heard at LLSB, thrill
 - **investigations:** ECG and CXR are normal; Echo to confirm diagnosis
 - **management:** most close spontaneously
- moderate-to-large VSD
 - epidemiology: CHF by 2 mo; late secondary pulmonary HTN if left untreated
 - clinical presentation

Moderate-to-Large VSD

Size of VSD is inversely related to intensity of murmur

- ♦ history: delayed growth, decreased exercise tolerance, recurrent URIs or “asthma” episodes
- ♦ physical exam: holosystolic murmur at LLSB, mid-diastolic rumble at apex, size of VSD is inversely related to intensity of murmur
- **investigations**
 - ♦ ECG: LVH, LAH, RVH
 - ♦ CXR: increased pulmonary vasculature, cardiomegaly, CHF
 - ♦ Echo: diagnostic
- **management:** treatment of CHF and surgical closure by 1 yr old

Patent Ductus Arteriosus

- patent vessel between descending aorta and left pulmonary artery (normally, functional closure within first 15 h of life, anatomical closure within first days of life)
- **epidemiology**
 - 5-10% of all congenital heart defects
 - delayed closure of ductus is common in premature infants (1/3 of infants <1,750 g); this is different from PDA in term infants
- natural history: spontaneous closure common in premature infants, less common in term infants
- **clinical presentation**
 - history: asymptomatic, or have apneic or bradycardic spells, poor feeding, accessory muscle use, CHF
 - physical exam: tachycardia, bounding pulses, hyperactive precordium, wide pulse pressure, continuous “machinery” murmur best heard at left infraclavicular area
- **investigations**
 - ECG: may show left atrial enlargement, LVH, RVH
 - ECHO is diagnostic
 - CXR: normal to mildly enlarged heart, increased pulmonary vasculature, prominent pulmonary artery
- **management**
 - indomethacin (Indocid®): antagonizes prostaglandin E₂, which maintains ductus arteriosus patency; only effective in premature infants
 - catheter or surgical closure if PDA causes respiratory compromise, FTT, or persists beyond 3rd mo of life

Figure 3. Patent duct arteriosus

Physical Exam for PDA (in term infant)

- Heavy “machinery” murmur
- High pulse rate
- Wide pulse pressure
- Hyperactive precordium
- Big bounding pulse

2. OBSTRUCTIVE LESIONS

- present with decreased urine output, pallor, cool extremities and poor pulses, shock, or sudden collapse

Coarctation of the Aorta

- **definition:** narrowing of aorta (almost always at the level of the ductus arteriosus)
- **epidemiology:** commonly associated with bicuspid aortic valve (50%); Turner syndrome (35%)
- **clinical presentation**
 - history: often asymptomatic
 - physical exam
 - ♦ blood pressure discrepancy between upper and lower extremities (increased suspicion/severity if >20 mmHg difference)
 - ♦ diminished or delayed femoral pulses relative to brachial (i.e. brachial-femoral delay)
 - ♦ possible systolic murmur with late peak at apex, left axilla, and left back
 - ♦ if severe, presents with shock in the neonatal period when the ductus arteriosus closes
- **investigations:** ECG shows RVH early in infancy, LVH later in childhood; Echo or MRI for diagnosis
- **prognosis:** can be complicated by HTN; if associated with other lesions (e.g. PDA, VSD) can lead to CHF
- **management:** give prostaglandins to keep ductus arteriosus patent for stabilization and perform surgical correction in neonates; for older infants and children balloon arterioplasty may be an alternative to surgical correction

Figure 4. Coarctation of the aorta

Aortic Stenosis

- 4 types: valvular (75%), subvalvular (20%), supra-valvular, and idiopathic hypertrophic subaortic stenosis (5%)
- **clinical presentation**
 - history: often asymptomatic, but may be associated with CHF, exertional chest pain, syncope, or sudden death
 - physical exam: SEM at RUSB with aortic ejection click at the apex (only for valvular stenosis)
- **investigations:** Echo for diagnosis
- **management:** valvular stenosis is usually treated with balloon valvuloplasty, patients with subvalvular or supra-valvular stenosis require surgical repair, exercise restriction required

Pulmonary Stenosis

- 3 types: valvular (90%), subvalvular, or supra-valvular
- **definition of critical pulmonary stenosis:** inadequate pulmonary blood flow, dependent on ductus for oxygenation, progressive hypoxia and cyanosis
- **natural history:** may be part of other congenital heart lesions (e.g. Tetralogy of Fallot) or in association with syndromes (e.g. congenital rubella, Noonan syndrome)
- **clinical presentation**
 - history: spectrum from asymptomatic to CHF
 - physical exam: wide split S₂ on expiration, SEM at LUSB, pulmonary ejection click (for valvular lesions)
- **investigations**
 - ECG findings: RVH
 - CXR: post-stenotic dilation of the main pulmonary artery (due to high velocity jet past stenotic valve)
 - Echo: diagnostic
- **management:** surgical repair if critically ill or if symptomatic in older infants/children

Cyanotic Congenital Heart Disease

- systemic venous return re-enters systemic circulation directly
- most prominent feature is cyanosis (O_2 sat <75%)
- hyperoxic test differentiates between cardiac and other causes of cyanosis
 - obtain preductal, right radial ABG in room air, then repeat after the child inspires 100% O_2
 - if PaO_2 improves to greater than 150 mmHg, cyanosis less likely cardiac in origin
- pre-ductal and post-ductal pulse oximetry
 - >5% difference suggests R to L shunt

1. RIGHT-TO-LEFT SHUNT LESIONS

Tetralogy of Fallot

- **epidemiology:** 10% of all CHD, most common cyanotic heart defect diagnosed beyond infancy with peak incidence at 2-4 mo of age
- **pathophysiology**
 - embryological defect due to anterior and superior deviation of the outlet septum leading to: VSD, RVOTO (i.e. pulmonary stenosis \pm subpulmonary valve stenosis), over-riding aorta, and RVH
 - ♦ infants may initially have a L \rightarrow R shunt (therefore no cyanosis); however, RVOTO is progressive, leading to increasing R \rightarrow L shunting with hypoxemia and cyanosis
 - ♦ degree of RVOTO determines the direction and degree of shunt and, therefore, the extent of clinical cyanosis and degree of RVH
- **clinical presentation**
 - history: hypoxic "tet" spells
 - ♦ during exertional states (crying, exercise) the increasing pulmonary vascular resistance and decrease in systemic resistance causes an increase in right-to-left shunting
 - ♦ clinical features include paroxysms of rapid and deep breathing, irritability and crying, increasing cyanosis, decreased intensity of murmur (decreased flow across RVOTO)
 - ♦ if severe, can lead to decreased level of consciousness, seizures, death
 - physical exam
 - ♦ single loud S2 due to severe pulmonary stenosis (i.e. RVOTO), SEM at LSB
- **investigations**
 - ECG: RAD, RVH
 - CXR: boot-shaped heart, decreased pulmonary vasculature, right aortic arch (in 20%)
 - Echo: diagnostic
- **management of spells:** O_2 , knee-chest position, fluid bolus, morphine sulfate, propranolol
- **treatment:** surgical repair at 4-6 mo of age; earlier if marked cyanosis or "tet" spells

2. OTHER CYANOTIC CONGENITAL HEART DISEASES

Transposition of the Great Arteries (TGA)

- **epidemiology:** 3-5% of all congenital cardiac lesions, most common cyanotic CHD in neonates
- **pathophysiology:** parallel pulmonary and systemic circulations
 - systemic: body \rightarrow RA \rightarrow RV \rightarrow aorta \rightarrow body
 - pulmonary: lungs \rightarrow LA \rightarrow LV \rightarrow pulmonary artery \rightarrow lungs
 - survival is dependent on mixing through PDA, ASD, or VSD
- **physical exam**
 - neonates: ductus arteriosus closure causes rapidly progressive severe hypoxemia unresponsive to oxygen therapy, acidosis, and death
 - VSD present: cyanosis is not prominent; CHF within first weeks of life
 - VSD absent: no murmur
- **investigations**
 - ECG: RAD, RVH, or may be normal
 - CXR: egg-shaped heart with narrow mediastinum ("egg on a string")
 - Echo: diagnostic
- **management**
 - symptomatic neonates: prostaglandin E1 infusion to keep ductus open until balloon atrial septostomy
 - surgical repair: arterial switch performed in the first two weeks in those without a VSD while LV muscle is still strong

Total Anomalous Pulmonary Venous Return

- **epidemiology:** 1-2% of CHD
- **pathophysiology**
 - all pulmonary veins drain into right-sided circulation (systemic veins, RA)
 - no direct oxygenated pulmonary venous return to left atrium
 - often associated with obstruction at connection sites
 - ASD must be present for oxygenated blood to shunt into the LA and systemic circulation
- **management:** surgical repair in all cases and required urgently for severe cyanosis

Causes of Cyanotic Heart Disease – 5T's
 Truncus arteriosus
 Transposition of the great vessels
 Tricuspid atresia
 Tetralogy of Fallot
 Total anomalous pulmonary venous return

Tetralogy of Fallot

1. VSD
2. RVOTO
3. Aortic root "overriding" VSD
4. RVH

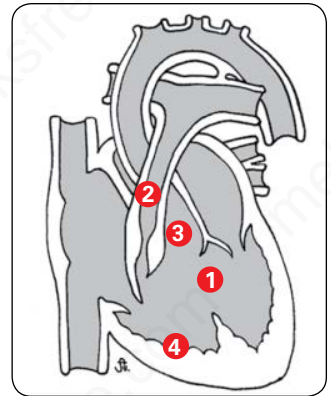

Figure 5. Tetralogy of Fallot

Figure 6. Transposition of the great arteries

Ebstein's Anomaly

- Septal and posterior leaflets of tricuspid valve are malformed and displaced into the RV
- Potential for RV dysfunction, tricuspid stenosis, tricuspid regurgitation, or functional pulmonary atresia if RV unable to open pulmonary valves
- Accessory conduction pathways (e.g. WPW) are often present

Etiology

- Unknown, associated with maternal lithium and benzodiazepine use in 1st trimester

Treatment

- Newborns: consider closure of tricuspid valve + aortopulmonary shunt, or transplantation
- Older children: tricuspid valve repair or valve replacement + ASD closure

Truncus Arteriosus

- **pathophysiology**
 - single great vessel gives rise to the aorta, pulmonary, and coronary arteries
 - truncal valve overlies a large VSD
 - potential for coronary ischemia with fall in pulmonary vascular resistance
- **management**: surgical repair within first 6 wk of life

Hypoplastic Left Heart Syndrome

- **epidemiology**: 1-3% of CHD; most common cause of death from CHD in first mo of life
- **pathophysiology**: LV hypoplasia may include atretic or stenotic mitral and/or aortic valve, small ascending aorta, and coarctation of the aorta with resultant systemic hypoperfusion
- systemic circulation is dependent on ductus patency; upon closure of the ductus, infant presents with circulatory shock and metabolic acidosis
- **management**
 - intubate and correct metabolic acidosis
 - IV infusion of prostaglandin E1 to keep ductus open
 - surgical palliation (overall survival 50% to late childhood) or heart transplant

4 Features of Hypoplastic Left Heart Syndrome

- Hypoplastic LV
- Narrow mitral/aortic valves
- Small ascending aorta
- Coarctation of the aorta

Congestive Heart Failure

- see [Cardiology and Cardiac Surgery, C34](#)

Etiology

- CHD
- cardiomyopathy (primary or secondary)
- high output circulatory states (e.g. anemia, AVMs, cor pulmonale, hyperthyroidism)
- non-cardiac (e.g. sepsis, renal failure)
- pressure overload (e.g. aortic stenosis/coarctation, pulmonary stenosis, HTN)
- volume overload (e.g. L to R shunt, valve insufficiency)

History

- infant: weak cry, irritability, feeding difficulties, early fatigability, diaphoresis while sleeping or eating, respiratory distress, lethargy, FTT
- child: decreased exercise tolerance, fatigue, decreased appetite, respiratory distress, frequent URIs or "asthma" episodes
- orthopnea, paroxysmal nocturnal dyspnea, pedal/dependent edema are all uncommon in children

Physical Findings

- 4 key features: tachycardia, tachypnea, cardiomegaly, hepatomegaly
- FTT
- alterations in peripheral pulses, four limb blood pressures (in some CHDs)
- dysmorphic features associated with congenital syndromes

Investigations

- CXR: cardiomegaly, pulmonary venous congestion
- ECG: sinus tachycardia, signs of underlying cause (heart block, atrial enlargement, hypertrophy, ischemia/infarct)
- Echo: structural and functional assessment
- blood work: CBC, electrolytes, BUN, Cr, LFTs

Management

- general: sitting up, O₂, sodium and water restriction, increased caloric intake
- pharmacologic: diuretics, afterload reduction (e.g. ACEI), β -blockers; digoxin rarely used
- curative: correction of underlying cause

4 Key Features of CHF

2 Tachy's and 2 Megaly's

- Tachycardia
- Tachypnea
- Cardiomegaly
- Hepatomegaly

Dysrhythmias

- see [Cardiology and Cardiac Surgery, C16](#)
- can be transient or permanent, congenital (structurally normal or abnormal), or acquired (toxin, infection, infarction)

Sinus Arrhythmia

- phasic variations with respiration (present in almost all normal children)

Sinus Tachycardia

- rate of impulses arising from sinus node is elevated (>150 bpm in infants, >100 bpm in older children)
- characterized by: beat-to-beat heart rate variability with changes in activity, P waves present/normal, PR constant, QRS narrow
- etiology: HTN, fever, anxiety, sepsis, anemia/hypoxia, PE, drugs, etc.
- differentiate from SVT (see below) by slowing the sinus rate (vagal massage, β -blockers) to identify sinus P waves

Pediatric vs. Adult ECG

Pediatric ECG findings that may be normal:

- HR >100 bpm
- Shorter PR and QT intervals and QRS duration
- Inferior and lateral small Q waves
- RV larger than LV in neonates, so normal to have:
 - RAD
 - Large precordial R waves
 - Upright T waves
 - Inverted T waves in the anterior precordial leads from early infancy to teen years

Premature Atrial Contractions

- may be normal variant or can be caused by electrolyte disturbances, hyperthyroidism, cardiac surgery, digitalis toxicity

Premature Ventricular Contractions

- common in adolescents
- benign if single, uniform, disappear with exercise, and no associated structural lesions
- if not benign, may degenerate into more severe dysrhythmias

Supraventricular Tachycardia

- abnormally rapid heart rhythm originating above the ventricles – most frequent sustained dysrhythmia in children
- no beat-to-beat HR variability, >220 bpm (infants) or >180 bpm (children), P waves absent/abnormal, PR indeterminable, QRS usually narrow
- pre-excitation syndromes (subset of SVT): WPW syndrome, congenital defect (see [Cardiology and Cardiac Surgery, C21](#))

Complete Heart Block

- congenital heart block can be caused by maternal anti-Ro or anti-La (e.g. mother with SLE)
- often diagnosed *in utero* (may lead to development of fetal hydrops)
- clinical symptoms related to level of block (the lower the block, the slower the heart rate and greater the symptoms of inadequate cardiac output)
- symptomatic patients need a pacemaker

Heart Murmurs

- 50-80% of children have audible heart murmurs at some point in their childhood
- most childhood murmurs are functional (e.g. “innocent”) without associated structural abnormalities and have normal ECG and radiologic findings
- in general, murmurs can become audible or accentuated in high output states (e.g. fever, anemia)

Table 11. Differentiating Heart Murmurs

	Innocent	Pathological
History and Physical	Asymptomatic	Symptoms and signs of cardiac disease (FTT, exercise intolerance)
Timing	SEM	All diastolic, pansystolic, or continuous (except venous hum)
Grade/Quality	<3/6; soft/blowing/vibratory	≥3/6 (palpable thrill); harsh
Splitting	Physiologic S2	May have fixed split or single S2
Extra Sounds/Clicks	None	May be present
Change of Position	Murmur varies	Unchanged

Table 12. Five Innocent Heart Murmurs

Type	Etiology	Location	Description	Age	Differential Diagnosis
Peripheral Pulmonic Stenosis	Flow into pulmonary branch arteries from main, larger, artery	Left upper sternal border	Neonates, low-pitched, radiates to axilla and back	Neonates, usually disappears by 3-6 mo	PDA Pulmonary stenosis
Still's Murmur	Flow across the pulmonic valve leaflets	Left lower sternal border	High-pitched, vibratory, LLSB or apex, SEM	3-6 yr	Subaortic stenosis Small VSD
Venous Hum	Altered flow in veins	Infraclavicular (R>L)	Infraclavicular hum, continuous, R>L	3-6 yr	PDA
Pulmonary Ejection	Flow through the pulmonic valve	Left upper sternal border	Soft, blowing, LUSB, SEM	8-14 yr	ASD Pulmonary stenosis
Supraclavicular Arterial Bruit	Turbulent flow in the carotid arteries	Supraclavicular	Low intensity, above clavicles	Any age	Aortic stenosis Bicuspid aortic valve

Infective Endocarditis

- see [Infectious Diseases, ID16](#)

Development

Approach to Global Developmental Delay

- also known as Early Developmental Impairment

Definition

- performance significantly below average in two or more domains of development (gross motor, fine motor, speech/language, cognitive, social/personal, activities of daily living) in a child <5 yr of age
- predict a diagnosis of intellectual disability in the future

Epidemiology

- 5-10% of children have neurodevelopmental delay
- careful evaluation can reveal a cause in 50-70% of cases

Etiology

- CNS abnormalities (meningitis/encephalitis, brain malformation, trauma, etc.)
- sensory deficits (hearing, vision)
- environmental (psychosocial neglect, lead exposure, antenatal drug or alcohol exposure, etc.)
- genetic/chromosomal disorders (DS, Fragile X, etc.)
- metabolic disorders (inborn errors of metabolism, hypothyroidism, iron deficiency, etc.)
- obstetrical (prematurity, HIE, TORCH infections, etc.)
- sleep disorders
- seizures

Clinical Presentation

- history
 - prenatal - intrauterine exposures (infections, alcohol), prenatal diagnosis,
 - obstetrical - complications, APGAR, infections, seizures, screening
 - pediatric - detailed developmental milestones: rate of acquisition, regression of skills
 - ♦ associated problems: feeding, seizures, behaviour, sleep
 - ♦ ototoxic antibiotics, frequently ear infections
 - family history, consanguinity
 - social history
- physical exam
 - micro/macrocephaly, dysmorphic features head-to-toe, hepatosplenomegaly, height and weight, detailed neurological examination
- investigations (guided by history and physical examination)
 - neurodevelopmental assessment, neuroimaging, vision and hearing test, EEG, sleep study
 - OT, PT, and/or SLP assessments
 - psychosocial evaluation
 - blood work (lead, CBC, ferritin, TSH)
 - metabolic screening (glucose, electrolytes, lactate, ammonia, liver function, pyruvate, albumin, triglycerides, uric acid, amino acids, urine organic acids, acylcarnitines, creatine phosphokinase)
 - neurologic - EEG or head CT
 - genetics consultation (microarray, Fragile X testing, testing for inborn errors of metabolism)

Management

- dependent on specific area of delay
- therapy services (e.g. speech and language therapy for language delay, OT and/or PT for motor delay), early intervention services (e.g. infant development services, Ontario Early Years Centres)

Intellectual Disability

Definition

- state of functioning that begins in childhood and is characterized by limitations in both intelligence and adaptive skills
- historically defined as an IQ <70
- often preceded by diagnosis of global developmental delay

Epidemiology

- 1% of general population; M:F = 1.5:1

Clinical Presentation

- history
 - earlier age of onset correlates with greater severity of ID
 - well below average general intellectual functioning
 - significant deficits in adaptive functioning in at least 2 of: communication, self-care, home-living, social skills, self-direction, academic skills, work, leisure, health, safety
- physical exam
 - check growth, dysmorphic features, complete physical exam

Classification of Intellectual Disability

Severity	% Cases	IQ
Mild	85	50-70
Moderate	10	35-49
Severe	3-4	20-34
Profound	1-2	<20

- investigations
 - standardized psychology assessment (includes IQ test and measure of adaptive functioning)
 - vision, hearing, and neurologic assessment
 - genetic and metabolic testing as indicated

Management

- main objective: enhance adaptive functioning level
- requires an interprofessional team with strong case coordination
- emphasize community-based treatment and early intervention
- individual/family therapy, behaviour management services, therapy services (e.g. OT, SLP), medications for associated conditions
- education: life skills, vocational training, communication skills, family education
- psychosocial support for individual and family; respite care

Prognosis

- higher rates of sensory deficits, motor impairment, behavioural/emotional disorders, seizures, psychiatric illness

Language Delay

Definition

- no universally accepted definition, but often identified around 18 mo of age with enhanced well baby visit
- if formally tested, at least one standard deviation below mean of age on standardized testing
- can be expressive (ability to produce or use language), receptive (ability to understand language), or both

Epidemiology

- M>F
- ~10-15% of 2 yr old children have a language delay, but only 4-5% remain delayed after 3 yr of age
- ~6-8% of school-aged children have specific language impairment (many of whom were not identified before school entry)

Etiology

- intellectual disability
- developmental disorders - cerebral palsy, Autism Spectrum Disorder
 - constitutional language delay
- genetic/metabolic: DS, Fragile X syndrome, Williams syndrome, hypothyroidism, PKU, etc.
- mechanical problems: cleft palate, cranial nerve palsy, hearing impairment
- medical condition: seizure disorder (includes acquired epileptic aphasia), CP, TORCH infection, iron deficiency, lead poisoning, etc.
- psychosocial: neglect or abuse
- selective mutism
- language specific learning disorder
- isolated language delay

Clinical Presentation

- history
 - concerns about hearing, delay in language development or regression in previously normal language development
 - delayed language milestones, presence of red flags, regression (*see Table 5 Developmental Milestones*)
 - must determine if language delay is expressive, receptive, or mixed
 - determine differences in behaviour at home, school, other social environments
 - risk factors: family history of speech and language delay, male, prematurity, low birth weight, hearing loss
- physical exam
 - guided by history: look for abnormal growth, dysmorphisms, unusual social interactions (lack of eye contact, not pointing)
 - include full exam of the external/internal ear (e.g. TM scarring), oral pharynx (e.g. cleft palate), and neurologic system (including tone)
- investigations
 - use of language specific screens in primary care setting: The Early Language Milestone
 - CAT/CLAMS, MCHAT, etc.
 - developmental evaluation
 - referred to an audiologist if hearing loss is suspected
 - CBC (to rule out anemia), venous blood lead levels, genetic/metabolic workup as indicated

Management

- specific to etiology
- often multidisciplinary and requires appropriate referrals: early intervention services, special education services, SLP, OHNS and dental professionals, general support services
- prevention: parents can read aloud to their child, engage in dialogic reading, avoid baby talk, narrate daily activities, etc.

Prognosis

- depends on etiology – best prognosis for developmental speech delay
- if language delay persists beyond 5 yr old, more likely to have difficulties in adulthood
- persistent language delay is associated with poor academic performance, behavioural problems, social isolation

Risk Factors for Sensorineural Hearing Loss

- Genetic syndromes/family history
- Congenital (TORCH) infections
- Craniofacial abnormalities
- <1,500 g birthweight
- Hyperbilirubinemia/kernicterus
- Asphyxia/low APGAR scores
- Bacterial meningitis, viral encephalitis

Bilingual exposure generally does NOT explain a frank delay in language development

Primary care physicians should suspect a receptive language delay in any young child with an expressive language delay

Specific Learning Disorder

Definition

- specific and persistent failure to acquire academic skills despite conventional instruction, adequate intelligence, and sociocultural opportunity
- a significant discrepancy between a child's intellectual ability and their academic performance
- types: reading (dyslexia), writing, mathematics (dyscalculia)

Epidemiology

- prevalence: 10%
- high incidence of psychiatric comorbidity: anxiety, dysthymia, conduct disorder, major depressive disorder, oppositional defiant disorder, ADHD

Etiology

- pathogenesis is unknown, likely genetic factors involved
- learning disabilities may be associated with a number of conditions:
 - genetic/metabolic: Turner syndrome, Klinefelter syndrome
 - perinatal: prematurity, low birth weight, birth trauma/hypoxia
 - postnatal: CNS damage, hypoxia, environmental toxins, FAS, psychosocial deprivation (understimulation), malnutrition
- poor visual acuity is NOT a cause

Risk Factors

- positive family history, prematurity, other developmental and mental health conditions, neurologic disorders (e.g. seizure disorders, neurofibromatosis), history of CNS infection/irradiation/traumatic injury

Clinical Presentation

- history and physical exam
 - school difficulties (academic achievement, behaviour, attention, social interaction, over-reliance on teacher)
 - development of negative self-concept → reluctance to participate even in areas of strength
 - social issues: overt hostility towards parents/teachers; difficulties making friends, bullying, and anxiety
 - look for dysmorphisms, complete physical exam
- investigations
 - psychoeducational assessment
 - individual scores on achievement tests in reading, mathematics, or written expression (WISC III, WRAT) >2 SD below that expected for age, education, and IQ
 - evaluate child's attention, memory, expressive language, coordination skills

Management

- provide quality instruction for specific learning disability
- support student by modifying the curriculum and/or providing accommodations (e.g. scribe for writing, extra time for tests, photocopied notes, etc.)
- consider grade retention in certain students (no guidelines exist, very rare in Ontario)
- specialized education placements that can provide educational remediation

Prognosis

- limited information available about persistence of learning disabilities over time
- low self-esteem, poor social skills, 40% school drop-out rate

Fetal Alcohol Spectrum Disorder

Definition

- term describing the range of effects of prenatal exposure to alcohol, including physical, mental, behavioural, and learning disabilities
- abstinence from alcohol during pregnancy is recommended
- spectrum includes: FAS, partial FAS, ARBD (alcohol related brain damage) and ARND (alcohol related neurodevelopmental disorder)

Epidemiology

- prevalence of FAS and FASD is 0.1% and 1.0%, respectively
- most common preventable cause of intellectual disability

Pathogenesis

- specific mechanism of FASD is unknown, but hypotheses include nutritional deficits, toxic effects of acetaldehyde, alteration of placental transport, abnormal protein synthesis, and altered cerebral neurotransmission

Diagnosis

- often misdiagnosed or missed entirely
- diagnosis of FAS, ARBD, and ARND all require evidence of maternal drinking during pregnancy
- criteria for diagnosis of FAS
 - growth deficiency: low birth weight and/or decelerating weight over time not due to nutrition
 - characteristic pattern of facial anomalies: short palpebral fissures (<2SD below mean), flattened philtrum, thin upper lip (having all 3 features is highly specific for alcohol exposure, don't need maternal history to confirm)
 - CNS dysfunction (need ≥ 3): motor skills; neuroanatomy/neurophysiology; cognition; language; academic achievement; memory; attention; executive function (impulse control and hyperactivity); affect regulation; adaptive behaviour, social skills or social communication OR microcephaly in infant and young children
- criteria for diagnosis of ARBD
 - congenital anomalies, including malformations and dysplasias of the cardiac, skeletal, renal, ocular, and auditory systems
- criteria for diagnosis of ARND
 - CNS dysfunction (similar to FAS)
 - complex pattern of behavioural or cognitive abnormalities inconsistent with developmental level that cannot be explained by familial background or environment alone

Management

- early diagnosis is essential to prevent secondary disabilities
- no cure, but individuals with FASD and their families should be linked to community resources and services to improve outcome

Prognosis

- secondary disabilities include unemployment, mental health problems, difficulties with the law, inappropriate sexual behaviour, disrupted school experience, peer problems

Attention Deficit Hyperactivity Disorder

- see [Psychiatry, Neurodevelopmental Disorders, PS38](#)

Autism Spectrum Disorder

- see [Psychiatry, Neurodevelopmental Disorders, PS37](#)

Motor Delay

- see [Cerebral Palsy, P83](#) and [Medical Genetics, Duchenne Muscular Dystrophy, MG7](#)

Endocrinology

Antidiuretic Hormone

Diabetes Insipidus

- see [Endocrinology, E18](#) and [Nephrology, NP11](#)

Syndrome of Inappropriate Antidiuretic Hormone

- see [Endocrinology, E18](#) and [Nephrology, NP10](#)

Diabetes Mellitus

DIABETES MELLITUS TYPE 1

- see [Endocrinology, Disorders of Glucose Regulation, E6](#)

Epidemiology

- most common form of DM in children, M=F
- variable prevalence internationally, affects ~1:4,000 children in Canada
- can present at any age, but bimodal peaks at 5-7 yr old and at puberty

Clinical Presentation

- can present as polyuria (often manifested as nocturia or secondary enuresis), polydipsia, weight loss (lack of insulin leading to a catabolic state), polyphagia, DKA (~20%) (see [Endocrinology, E11](#))

Diagnostic Criteria for DM (Types 1 and 2) in Children

1. Symptoms (polyuria, polydipsia, weight loss, etc.) and hyperglycemia (Random glucose ≥ 11.1 mmol/L)

OR

2. Two of the following on one occasion:
 - Fasting glucose ≥ 7.0 mmol/L
 - 2 h plasma glucose during OGTT ≥ 11.1 mmol/L
 - Random glucose ≥ 11.1 mmol/L (not appropriate for confirmatory testing)

OR

3. One of the following on two separate occasions*
 - Fasting glucose ≥ 7.0 mmol/L
 - 2 h plasma glucose during OGTT ≥ 11.1 mmol/L
 - Random glucose ≥ 11.1 mmol/L (not appropriate for confirmatory testing)

*Random glucose is not appropriate for confirmatory (second) testing

Management

- patients and families are best managed with a family-centred pediatric multidisciplinary team able to provide education, ongoing care, and psychosocial support surrounding survival skills, meal plans, and insulin injections as a cornerstone of treatment
 - diet with consistent levels of carbohydrates, avoiding foods with high glycemic index is advised
 - exercise recommended, extensive activity involving legs (walking, cycling, running) may cause prolonged hypoglycemia
 - administer influenza immunization yearly to avoid complications to management
- blood glucose monitoring is especially important in children as they are more susceptible to hypoglycemia
 - administer glucagon or dextrose for severe hypoglycemia
- if DKA present: ABCs, 100% O₂, admit, monitor, correct fluid losses, conduct ECG (assess abnormal T waves), administer insulin and restore glucose gradually (first SC and then IV if no improvement), correct electrolyte disturbances, identify/treat precipitating event, avoid complications (i.e. cerebral edema)
 - low threshold to investigate (CT/MRI) and treat DKA, as cerebral edema is a major concern
 - signs of neurological deterioration – headache, bradycardia, irritability, decrease LOC, incontinence, specific neurological signs)
 - administer mannitol for cerebral edema
 - frequent BG, fluid and electrolyte monitoring
 - see [Endocrinology, E11](#)
- screen for micro- and macrovascular complications (regular ophthalmology assessments, BP, microalbuminuria), concurrent autoimmune diseases (thyroiditis, celiac disease, etc.), and mental health issues (depression, eating disorders), hypertension, dyslipidemia

Prognosis

- no cure currently
- short-term complications
 - hypoglycemia
 - due to missed/delayed meals, excess insulin or exercise, illness
 - can lead to seizures and/or coma
 - reversed with PO/IV glucose or IM glucagon
 - hyperglycemia
 - due to intercurrent illness, diet-to-insulin mismatch
 - risk of end-organ damage
 - DKA: due to missed insulin doses, infection; most common cause of death
- long-term complications
 - microvascular: retinopathy, nephropathy, neuropathy
 - macrovascular: metabolic syndrome, CVD, CAD, PVD
 - increased risk of other autoimmune diseases
 - hypertension, dyslipidemia

DIABETES MELLITUS TYPE 2

- see [Family Medicine, FM22](#), and [Endocrinology, E7](#)
- impaired glucose metabolism due to increased peripheral insulin resistance
- rare before 10 yr of age, but more common in older children/adolescents
- prevalence is rising mainly due to the increased incidence of childhood obesity
- risk factors: obesity, positive family history, female gender, PCOS, hyperglycemia exposure *in utero*, certain ethnic groups
 - risk reduced with breastfeeding
- clinical presentation may be similar to that of type 1 DM, though most children are asymptomatic
- may present in DKA or hyperglycemic hyperosmotic nonketotic state
 - investigation – fasting plasma glucose recommended, oral glucose tolerance test for very obese children with multiple risk factors
- management
 - insulin used for severe metabolic decompensation at diagnosis (DKA, A1C > 9%), can wean off
 - initiate lifestyle modification program, including diet, weight loss, physical activity (moderate-to-vigorous activity for at least 60 min/d; screen time less than 2 h/d)
 - glycemic target: HbA1c ≤ 7%
 - if glycemic targets not achieved within 3-6 mo from diagnosis with lifestyle intervention alone, either metformin (first line), glimepiride, or insulin should be initiated
 - metformin can be initiated at diagnosis if HbA1c > 7%
 - monitor HbA1c every 3 mo
 - advise patient to monitor finger-stick blood glucose levels if on medication with risk of hypoglycemia, are changing medication regimen, have not met treatment goals, or have intercurrent illness
 - screening – same as T1D plus annual screening for PCOS and NAFLD
- prognosis: includes microvascular and macrovascular complications similar to type 1 DM

Blood Glucose Targets by Age

Age range	Pre-meal blood glucose target	HbA1c target
<6	6-10	<8%
6-12	6-10	<7.5%
>12	4-7	<7%

Management of Newly Diagnosed Type 2 DM in Children and Adolescents

Pediatrics 2013;131(2):364-82

Key Action Statements

- Clinicians should ensure that insulin therapy is initiated for children and adolescents with type 2 DM who are ketotic or in DKA and in whom the distinction between types 1 and 2 DM is unclear and, in usual cases, should initiate insulin therapy for patients
 - who have random venous or plasma BG concentrations 14 mmol/L; or
 - whose HbA1c is > 9%.
- Clinicians should initiate a lifestyle modification program, including nutrition and physical activity, and start metformin as first-line therapy for children and adolescents at the time of diagnosis of type 2 DM.
- The committee suggests that clinicians monitor HbA1c concentrations every 3 mo and intensify treatment if treatment goals for finger-stick BG and HbA1c concentrations are not being met.
- Clinicians should advise patients to monitor finger-stick BG concentrations in patients who
 - are taking insulin or other medications with a risk of hypoglycemia; or
 - are initiating or changing their diabetes treatment regimen; or
 - have not met treatment goals; or
 - have intercurrent illnesses.
- Clinicians should incorporate the Academy of Nutrition and Dietetics' Pediatric Weight Management Evidence-Based Nutrition Practice Guidelines in their dietary or nutrition counselling of patients with type 2 DM at the time of diagnosis and as part of ongoing management.
- Clinicians should encourage children and adolescents with type 2 DM to engage in moderate-to-vigorous exercise for at least 60 min daily and to limit nonacademic "screen time" to less than 2 h/d.

Growth (see FTT)

APPROACH TO SHORT STATURE

Definition

- short stature: height < 3rd percentile
- poor growth evidenced by growth deceleration (height crosses major percentile lines, growth velocity < 25th percentile)

Epidemiology

- ~2.5% of the population by definition

Etiology

- see sidebar

Clinical Presentation

- history and physical exam
 - plot on growth curve (special growth charts available for Turner syndrome, achondroplasia, DS)
 - assess for dysmorphic features, disproportionate short stature
 - risk factors for GH deficiency: previous head trauma, history of intracranial bleed or infection, head surgery or irradiation, positive family history, breech delivery
 - decreased growth velocity may be more worrisome than actual height
- investigations
 - calculate mid-parental height: children are usually in a percentile between their parents' height (mid-parental height = (mother + father's height in cm ± 12.5cm)/2)
 - AP x-ray of left hand and wrist for bone age
 - GH testing
 - remaining investigations guided by history and physical (e.g. TSH, sweat chloride, etc.)

Management

- depends on severity of problem as perceived by parents/child
- no treatment for non-pathological short stature, except for idiopathic short stature
- GH therapy for GH deficiency: if administered at an early age, can help patients achieve adult height
- requirements
 - GH shown to be deficient by 2 different stimulation tests (with arginine, glucagon, insulin)
 - growth velocity <3rd percentile or height <<3rd percentile
 - bone age x-rays show unfused epiphyses/delayed bone age
- support and management of resultant self-image issues, social anxiety, etc.

Short Stature DDx

ABCDEFG

- Alone (neglected infant)
- Bone dysplasias (rickets, scoliosis, mucopolysaccharidoses)
- Chromosomal (Turner, Down)
- Delayed growth (constitutional)
- Endocrine (low GH, Cushing, hypothyroid)
- Familial
- GI malabsorption (celiac, Crohn's)

4 Questions to Ask when Evaluating Short Stature

- Was there IUGR?
- Is the growth proportionate?
- Is the growth velocity normal?
- Is bone age delayed?

To check for proportionality, measure upper to lower segment ratio (U/L) using the pubic symphysis as your landmark. Normals are 1.7 for newborn, 1.4 for young child, 0.9 for adult male, 1.0 for adult female

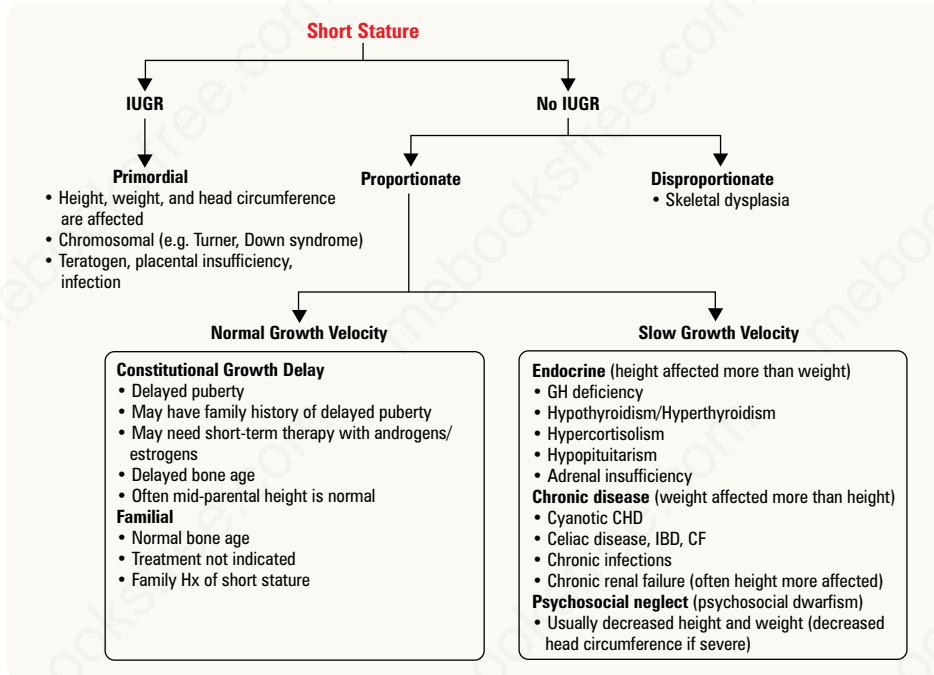

Figure 7. Approach to the child with short stature

TALL STATURE

- height greater than two SD above the mean for a given age, sex, and race

Etiology

- constitutional/familial
- endocrine: Beckwith-Wiedemann syndrome, hyperthyroidism, hypophyseal gigantism, precocious puberty
- genetic: homocystinuria, Klinefelter syndrome, Marfan syndrome, Sotos syndrome

Hypercalcemia/Hypocalcemia/Rickets

- see [Endocrinology, E37, E39, E42](#)

Hyperthyroidism and Hypothyroidism

- may be congenital or acquired (for acquired causes, see [Endocrinology, E22](#))

CONGENITAL HYPERTHYROIDISM

- also known as neonatal Graves' disease

Epidemiology

- ~1:25,000 neonates, M=F

Etiology

- may be classified as permanent or transient congenital hypothyroidism (CH)
 - subcategorize into primary (85% dysgenesis, 15% thyroid gland disorder), secondary/central (pituitary/hypothalamic issue), or peripheral CH (deficits in thyroid hormone transport, metabolism or action)
 - permanent CH requires lifelong treatment, transient CH recovers to normal thyroid after neonatal period
- causes of transient hypothyroidism: maternal - antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications; neonatal - neonatal iodine deficiency/excess, congenital liver hemangiomas, certain gene mutations

Clinical Presentation

- history and physical exam
 - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
 - prolonged jaundice, feeding difficulty, lethargy, constipation, umbilical hernia, macroglossia, large fontanelles, puffy face, swollen eyes
 - examine for congenital malformations (especially cardiac) and dysmorphic features
 - most commonly presents as a positive newborn screen result
- investigations
 - screen all infants for primary CH, repeat screening at 2 wk for infants at high risk: preterm, (very)-low birth weight, infants in NICU, specimen collection <24 h of life, multiple births
 - diagnosis through newborn screening of TSH (most sensitive for primary CH) or free T4; abnormal results should be confirmed with serum levels from venipuncture
 - ♦ ↑ TSH, ↓ free T4 in primary CH
 - ♦ ↓ TSH, ↓ free T4 in secondary CH
 - primary CH (optional) - radioisotope scanning/ultrasound of thyroid for severity, serum thyroglobulin, maternal antithyroid antibodies, urinary iodine
 - secondary CH: MRI, gene analysis, eye exam for optic nerve hypoplasia (assess pituitary)

Management

- thyroxine replacement, hormone normalization should be done within 2 wk to avoid cognitive impairment

Prognosis

- excellent outcome if treatment started within 1-2 mo of birth
- if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound), intellectual impairment, poor growth, hearing loss

CONGENITAL HYPOTHYROIDISM

Epidemiology

- incidence: 1:4,000-1:20,000 newborn births; F:M = 2:1
- one of the most common preventable causes of intellectual disability

Etiology

- may be classified as permanent primary, central, or transient hypothyroidism
- ~85% of primary cases are sporadic (mostly thyroid dysgenesis), remaining 15% hereditary (mostly inborn errors of thyroid synthesis)
- causes of transient hypothyroidism: maternal antibody-mediated, iodine deficiency (rare in developed countries), prenatal exposure to antithyroid medications

Clinical Presentation

- history and physical exam
 - usually asymptomatic in neonatal period because maternal T4 crosses the placenta
 - prolonged jaundice, constipation, sluggish, hoarse cry, lethargy, poor feeding, macroglossia, coarse facial features, large fontanelles, umbilical hernia
- investigations
 - diagnosis through newborn screening of TSH or free T4; abnormal results should be confirmed with serum levels from venipuncture

Management

- thyroxine replacement

Prognosis

- excellent outcome if treatment started within 1-2 mo of birth
- if treatment started after 3-6 mo of age, may result in permanent developmental delay and/or disability (mild to profound)

Sexual Development

AMBIGUOUS GENITALIA**Definition**

- newborn or child whose gender is difficult to assign based on the appearance of genitalia
- subtype of DSD: a condition in which development of chromosomal, gonadal, or anatomic sex is atypical
- subtypes: 46,XX DSD, 46,XY DSD, ovotesticular DSD (true hermaphrodite)

Epidemiology

- incidence of genital abnormalities at birth is as high as 1:300
- prevalence of complex anomalies with true sexual ambiguity much lower at ~1:5,000

Etiology

- 46,XY DSD
 - inborn error of testosterone biosynthesis or Leydig cell hypoplasia
 - 5- α -reductase deficiency, androgen receptor deficiency or insensitivity
 - LH/hCG unresponsiveness
- 46,XX DSD
 - virilizing CAH (most common)
 - maternal source: virilizing ovarian or adrenal tumours, untreated maternal CAH, placental aromatase deficiency
- ovotesticular DSD
 - both ovarian follicles and seminiferous tubules in the same patient with a 46,XX karyotype
 - mixed gonadal dysgenesis

Risk Factors

- parental consanguinity, positive family history of ambiguous genitalia, early childhood illness/death, or primary amenorrhea, maternal medications during pregnancy (e.g. androgens, progesterones, danazol, phenytoin, aminoglutethimide, endocrine disruptors)

Clinical Presentation

- history
 - thorough obstetrical history, including prenatal screens and maternal medications
 - family history: autosomal recessive pattern may suggest CAH, X-linked recessive pattern may suggest androgen insensitivity syndrome
- physical exam
 - male pseudohermaphrodite (XY): small phallus, hypospadias, undescended testicles
 - female pseudohermaphrodite (XX): clitoral hypertrophy, labioscrotal fusion
 - look for concurrent midline defects, dysmorphic features, and congenital abnormalities
- investigations
 - karyotype and genetic workup as indicated
 - blood work: electrolytes and renin (evidence of salt-wasting in CAH); 17-OH-progesterone, androgens, FSH, and LH
 - imaging: abdominal U/S to look for uterus, testicles, ovaries

Management

- avoid announcement of probable sex or use of personal pronouns until all tests are complete
- continuous psychosocial support for parents and child during development
- elective surgical reconstruction of genitalia is sometimes possible

CONGENITAL ADRENAL HYPERPLASIA**Definition**

- autosomal recessive disorder characterized by the partial or total defect of various synthetic enzymes required for cortisol and aldosterone production in the adrenal cortex
 - adrenal cortex normally produces balanced levels of aldosterone, cortisol and androgens

Epidemiology

- occurs in ~1:15,000 live births
- most common cause of ambiguous genitalia in genotypically normal females (46XX)

Etiology

- for biosynthetic pathways of adrenal cortex, see [Endocrinology, E29](#)
- 21-OH responsible for ~95% of CAH cases
- results in \downarrow cortisol and aldosterone production with shunting toward $\uparrow\uparrow$ androgens
- cortisol deficiency leads to elevated ACTH, which causes adrenal hyperplasia
- rarer causes include deficiencies in 11-OH, cholesterol desmolase, 17-OH, and 3-HSD

Clinical Presentation

- depends on which enzyme in cortisol synthesis pathway is defective
- presentation of 21-OH deficiency can be divided into
 - classic deficiency with salt wasting: inadequate aldosterone resulting in FTT, hyperkalemia, hyponatremia, hypoglycemia, acidosis (majority of classic CAH types)
 - classic deficiency without salt wasting: simple virilization with adequate aldosterone levels
 - ♦ females typically present with amenorrhea, precocious puberty, polycystic ovaries, hirsutism
 - ♦ males typically asymptomatic at birth, may show hyperpigmentation (from overproduction of melanocyte stimulating hormone), penile enlargement, rapid growth and accelerated skeletal maturation; present with signs of virilization later in life
 - non-classic CAH – mild androgen excess, sometimes asymptomatic, virilization present later in life, rarely associated with Addisonian crises
- 21-OH deficiency screening is part of many newborn screening programs across North America
- high serum levels of 17-OH progesterone in random blood sample diagnostic for 21-OH deficiency
 - assess plasma ACTH, serum electrolytes, plasma glucose, plasma aldosterone, plasma renin activity, blood gas
 - ultrasound – look for enlarged adrenal gland and presence of uterus

Management

- correct any abnormalities in fluids, electrolytes, or serum glucose
- provide glucocorticoids (e.g. hydrocortisone)/mineralocorticoids (fludrocortisone) as necessary to reduce ACTH levels, extra glucocorticoids in times of stress
- psychosocial support

Prognosis

- complications if untreated include virilization, acne, salt wasting, hypotension

NORMAL PUBERTAL DEVELOPMENT**Physiology**

- puberty occurs with the maturation of the HPG axis
- ↑ pulsatile release of GnRH → ↑ release of LH and FSH → maturation of gonads, release of sex steroids → secondary sexual characteristics
- adrenal production of androgens also required

Females

- onset: age 8-13 yr old (may start as early as 7 yr in girls of African descent)
- usual sequence
 1. thelarche: breast budding
 2. pubarche: axillary hair, body odour, mild acne
 3. growth spurt
 4. menarche: mean age 12.5 yr; indicates that growth spurt is almost complete; menses may be irregular in duration and length of cycle
- early puberty is common and often constitutional, late puberty is rare (rule out organic causes)

Males

- onset: age 9-14 yr old
- usual sequence
 1. testicular enlargement
 2. penile enlargement
 3. pubarche: axillary and facial hair, body odour, mild acne
 4. growth spurt: occurs later in boys
- early puberty is uncommon (rule out organic causes), late puberty is common and often constitutional
- gynecomastia (transient development of breast tissue) is a common self-limited condition seen in 50% of males during puberty (but any discharge from nipple or fixed mass should be investigated)

Tanner Staging

- scale used in pediatrics that defines physical measurements of development based on external primary and secondary sex characteristics

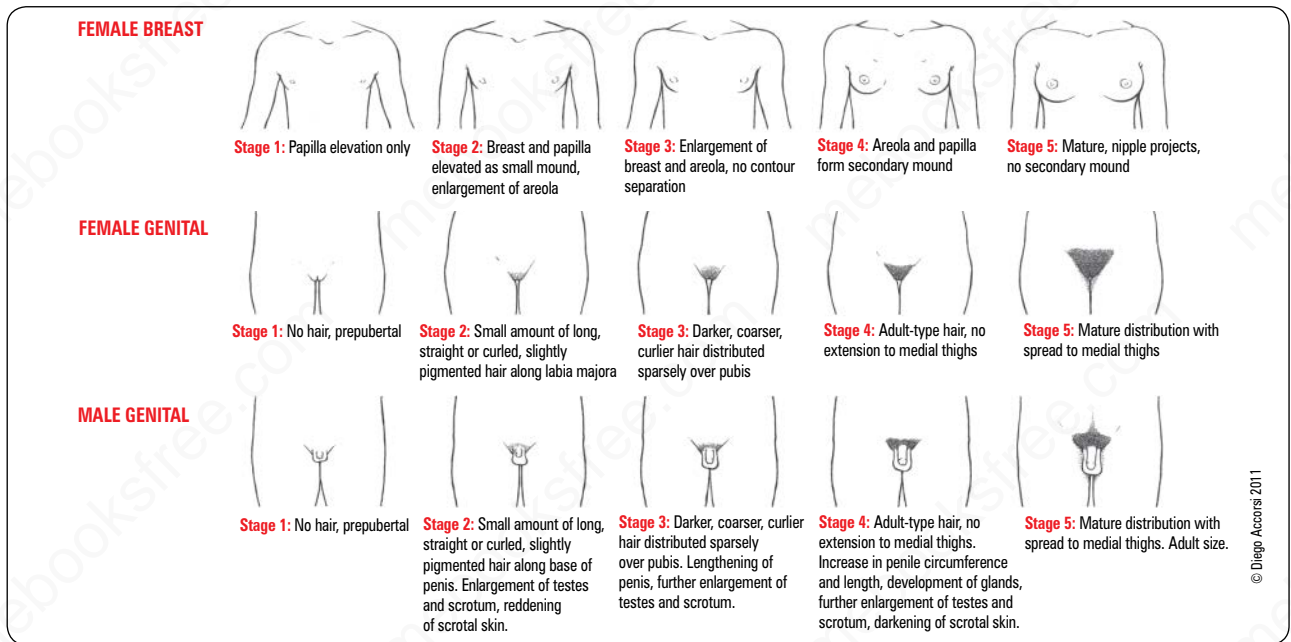

Figure 8. Tanner staging

PRECOCIOUS PUBERTY

Definition

- development of secondary sexual characteristics 2-2.5 SD before population mean
- <8 yr old for females, <9 yr old for males

Epidemiology

- 1/10,000; F>M

Etiology

- usually idiopathic in females (90%), more suggestive of pathology in males (50%)
- central (GnRH dependent)
 - hypergonadotropic hypergonadism; hormone levels as in normal puberty
 - premature activation of the HPG axis
 - differential diagnosis: idiopathic or constitutional (most common in females), CNS disturbances (tumours, hamartomas, post-meningitis, increased ICP, radiotherapy), NE, primary severe hypothyroidism
- peripheral (GnRH independent)
 - hypogonadotropic hypergonadism
 - differential diagnosis: adrenal disorders (CAH, adrenal neoplasm), testicular/ovarian tumour, gonadotropin/hCG secreting tumour (hepatoblastoma, intracranial teratoma, germinoma), exogenous steroid administration, McCune-Albright syndrome, aromatase excess syndrome, rarely hypothyroidism (Van Wyk-Grumbach syndrome), primary severe hypothyroidism

Clinical Presentation

- history
 - symptoms of puberty, family history of precocious puberty, medical illness
- physical exam
 - growth velocity
 - prepubertal: 4 to 6 cm/yr
 - growth spurt: boys 8-10 cm/yr, girls 6-8 cm/yr
 - complete physical exam, including Tanner staging and neurological assessment
- investigations
 - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, DHEA-S, 17-OH-progesterone)
 - secondary tests: MRI head, pelvic U/S, β -hCG, GnRH, and/or ACTH stimulation test

A child with proven central precocious puberty should receive an MRI of the brain

Management

- indications for medical intervention to delay progression of puberty: rapid advancement of puberty, early age, risk of compromise of final adult height, psychological
- central causes: goals are to preserve height and alleviate psychosocial stress; GnRH agonists (e.g. leuprolide) most effective
- peripheral causes: goal is to limit effects of elevated sex steroids; treat underlying cause; medications that decrease the production of a specific sex steroid or block its effects (e.g. ketoconazole, spironolactone, tamoxifen, anastrozole), surgical intervention

DELAYED PUBERTY

Definition

- failure to develop secondary sex characteristics by 2-2.5 SD beyond the population mean
 - for males: lack of testicular enlargement by 14 yr old
 - for females: lack of breast development by 13 yr old OR absence of menarche by 16 yr old or within 5 yr of pubertal onset

Epidemiology

- M>F

Etiology

- usually constitutional delay in males, more suggestive of pathology in females
- central causes
 - constitutional delay in activation of HPG axis (most common)
 - hypogonadotropic hypogonadism
- peripheral causes
 - hypergonadotropic hypogonadism (e.g. primary gonadal failure, gonadal damage, Turner syndrome, hormone deficiency, androgen insensitivity syndrome, etc.)

Clinical Presentation

- history: weight loss, short stature, family history of puberty onset, medical illness, high performance athletes (females)
- physical exam: growth velocity (minimum 4 cm/yr), Tanner staging, neurological exam, complete physical exam
- investigations
 - initial screening tests: bone age, serum hormone levels (estradiol, testosterone, LH, FSH, TSH, free T4, IGF-1), CBC, electrolytes, BUN, Cr, LFTs, liver enzymes, ESR, CRP, urinalysis
 - secondary tests: MRI head, pelvic U/S, karyotype, IBD panel, celiac disease panel, LH levels following GnRH agonist

Management

- identify and treat underlying cause
- hormonal replacement: cyclic estradiol and progesterone for females, testosterone for males

Gastroenterology

Vomiting

History

- characteristic of emesis (e.g. projectile, bilious, bloody)
- pattern of emesis (e.g. association with feeds, cyclic, morning)
- associated symptoms (e.g. anorexia, diarrhea, etc.)
- red flags: bilious or bloody emesis, projectile vomit, abdominal distension and tenderness, high fever, signs of dehydration
- note that vomiting without diarrhea is most likely not gastroenteritis.
 - post tussive vomiting is also common with coughing fits in children

Physical Findings

- vital signs to determine clinical status and hydration state

Investigations

- CBC, electrolytes, BUN, Cr, amylase, lipase, glucose done routinely
- in sick child, add: ESR, venous blood gases, C&S (blood, stool), imaging

Vomiting: forceful expulsion of stomach contents through the mouth

Regurgitation: the return of partially digested food from the stomach to the mouth

Pyloric Stenosis 3 Ps

Palpable mass

Peristalsis visible

Projectile vomiting (2-4 wk after birth)

Table 13. Common Differential Diagnosis, Associated Findings, and Diagnostic Approach Based on Age

Cause	Suggestive Findings	Diagnostic Approach
NEONATES – NON-BILIOUS		
Tracheoesophageal Fistula	Vomiting, excessive secretions soon after birth (e.g. drooling, choking, respiratory distress), inability to feed, inability to advance NG tube	Inability to advance NG tube, CXR, upper GI series with water-soluble contrast
Pyloric stenosis	Projectile vomiting immediately after feeding, dehydrated, palpable "olive" in RUQ, decreased stools, hunger	U/S of pylorus, upper GI study (if U/S not diagnostic) Electrolytes, ABG (hypokalemic, hypochloremic metabolic alkalosis)
GERD	Fussiness after feeds, spit ups, arching of back, poor weight gain	Empiric trial of acid suppression, pH monitoring study, upper GI study, endoscopy
Sepsis	Fever, lethargy, tachycardia, tachypnea, widening pulse pressure	CBC, cultures (blood, urine, CSF), CXR
Inborn error of metabolism	Poor feeding, FTT, jaundice, hepatosplenomegaly, cardiomyopathy, dysmorphism, developmental delay	Electrolytes, ABG (hyponatremic, hyperkalemic metabolic acidosis), lactate, ammonia, LFTs, BUN, Cr, serum glucose, bilirubin, PT/PTT, CBC

Table 13. Common Differential Diagnosis, Associated Findings, and Diagnostic Approach Based on Age (continued)

Cause	Suggestive Findings	Diagnostic Approach
NEONATES – BILIOUS		
Intestinal obstruction – malrotation with volvulus, meconium ileus	Bilious emesis, abdominal distension, pain, bloody stool, shock	AXR, upper GI series, contrast enema
Duodenal atresia/stenosis	Bilious emesis, abdominal distension, often seen in DS, jaundice, polyhydramnios during pregnancy. Hypokaemic, hypochloremic metabolic alkalosis.	AXR, upper GI series ('double bubble' sign)
Hirschsprung's disease	Bilious emesis, abdominal distension, pain, failure to pass stool	AXR, upper GI series, contrast enema, rectal biopsy
CHILDREN AND ADOLESCENTS		
Acute viral gastroenteritis	Diarrhea, fever, sick contact, recent travel	CBC, stool culture
Appendicitis	Periumbilical discomfort that later localizes to RLQ, fever, anorexia	Abdominal U/S
Intussusception	Colicky progressive abdominal pain, drawing of legs up to chest, lethargy, bloody "red currant jelly" stool (Triad)	Abdominal U/S
Non-GI infection (e.g. meningitis)	Fever, localized findings depending on cause	Cultures (CSF, blood, urine), brain imaging, CXR
Increased ICP	Nocturnal waking, progressive recurrent headache worse with Valsalva, nuchal rigidity	Brain CT without contrast Therapeutic LP in idiopathic intracranial HTN
Toxic ingestion	Finding possibly varying by substance- toxidrome, often a history of ingestion	Qualitative and sometimes quantitative levels (urine, blood)
Pregnancy	Amenorrhea, morning sickness, bloating, breast tenderness	Urine β -hCG
Cyclic vomiting	At least 3 self-limited episodes of vomiting lasting 12 h, 7 d between episodes, no organic cause of vomiting	Diagnosis of exclusion

Management

- rehydration (see *Fluids and Electrolytes, P69*)
- treat underlying cause
 - antiemetic drugs can be used in children >2 years with severe vomiting is severe: promethazine, prochlorperazine, metoclopramide, ondansetron

Gastroesophageal Reflux**Epidemiology**

- extremely common in infancy (up to 50%) but rarely causes GERD (GER disease)

Clinical Presentation

- vomiting typically soon after feeding, non-bilious, rarely contains blood, small volume (<30 mL)
 - when to suspect gastroesophageal reflux disease (GERD), defined as when GER causes troublesome symptoms/complications
 - ♦ infant: poor weight gain, irritability, sleep disturbance, respiratory symptoms (coughing, choking, wheezing)
 - ♦ older child/adolescent: abdominal pain/heart burn, dysphagia, asthma, recurrent pneumonia/upper respiratory infections, recurrent otitis media, upper airway symptoms (chronic cough, hoarseness), dental erosions

Investigations

- thriving baby requires no investigation
- GERD can be a clinical diagnosis but diagnostic investigations may include
 - upper GI tract radiography – assesses anatomy and motility disorder
 - esophageal pH – quantify GER
 - upper endoscopy and esophageal biopsy – rule out other conditions that mimic GERD symptoms, assess GERD-related esophageal injury
 - warning signs of associated disorders requiring further investigations: bilious vomiting, GI tract bleeding, consistently forceful vomiting, fever, lethargy, hepatosplenomegaly, bulging fontanelle, micro/macrocephaly, seizures, abdominal tenderness/distension, suspected genetic, metabolic syndrome or chronic disease

Management

- conservative (infant): thickened feeds, frequent and smaller feeds, elevation of head, changing formula to hydrolyzed protein or amino acid based formula
 - breastfeeding infants – mothers exclude milk and egg in diet
 - older children/adolescent – same as adult management (see *Gastroenterology, G6*)
- medical
 - short-term parenteral feeding to enhance weight gain
 - ranitidine, PPI: decreases gastric acidity, decreases esophageal irritation
 - domperidone, metoclopramide: improves gastric emptying and GI motility; safety concerns and limited efficacy, should be reserved for children with gastroparesis contributing to GERD
- surgical: indicated for failure of medical therapy (Nissen fundoplication)

Complications

- esophagitis, strictures, Barrett's esophagus, FTT, aspiration, oral feeding aversion

Tracheoesophageal Fistula

- see [General Surgery, GS64](#)

Pyloric Stenosis

- see [General Surgery, GS62](#)

Duodenal Atresia

- see [General Surgery, GS63](#)

Malrotation of the Intestine

- see [General Surgery, GS63](#)

Diarrhea

- definition of diarrhea varies with diet and age (stool normalcy difficult to define in children)
- infants → increase in stool frequency to twice as often per day; older children → 3+ loose or watery stools/d
- duration: acute: <2 wk; chronic: >2 wk

Diarrhea is defined as an increase in frequency and/or decreased consistency of stools compared to normal

Normal stool volume
Infants: 5-10 g/kg/d
Children: 200 g/d

Pathophysiology

- osmotic: due to non-absorbable solutes in GI tract (e.g. lactose intolerance)
- secretory: increased secretion of Cl⁻ ions and water in intestinal lumen (e.g. bacterial toxin)
- malabsorption: less time for absorption due to increased motility or less villi to absorb (e.g. short bowel syndrome)

History

- frequency, duration, quality of diarrhea
- associated symptoms (e.g. fever, abdominal pain, hematochezia, etc.)
- recent antibiotic use or recent travel
- elements of diet

Diarrhea Red Flags

Bloody stool, fever, petechiae or purpura, signs of severe dehydration, weight loss/FTT

Physical Findings

- vital signs to determine clinical status and hydration state

Investigations

- acute diarrhea
 - stool for C&S, O&P, electron microscopy for viruses, *C. difficile* toxin, microscopy (leukocytes suggestive of invading pathogen), blood and urine cultures, blood work
- chronic diarrhea
 - serial heights, weights, growth percentiles
 - if child growing well and thriving, workup is limited (stool cultures as above, stool reducing substances)
 - red flags: poor growth, chronic rash, other serious infections, hospitalizations for dehydration
 - require full workup (as per below)
 - stool: consistency, pH, reducing substances, microscopy, occult blood, O&P, C&S, *C. difficile* toxin, 3 d fecal fat, α-1-antitrypsin clearance, fecal elastase
 - urinalysis, urine culture
 - CBC, differential, ESR/CRP, smear, electrolytes, total protein, albumin, carotene, Ca²⁺, PO₄³⁻, Mg²⁺, Fe, ferritin, folate, fat-soluble vitamins, PTT, INR
 - sweat chloride, celiac screen, thyroid function tests, urine VMA and HVA, HIV test, lead levels
 - CXR, upper GI series and follow-through
 - specialized tests: endoscopy, small bowel biopsy

Common Antibiotics that Can Lead to *C. difficile* Infection

- Fluoroquinolones
- Clindamycin
- Penicillin (broad spectrum)
- Cephalosporins (broad spectrum)

Differential Diagnosis

Table 14. Differential Diagnosis of Diarrhea

Infectious		Non-infectious		
Acute	Viral	Bacterial	Parasitic	Antibiotic-induced
	Rotavirus Norwalk Enteric adenovirus	<i>Salmonella</i> <i>Campylobacter</i> <i>Shigella</i> Pathogenic <i>E. coli</i> <i>Yersinia</i> <i>C. difficile</i>	<i>Giardia lamblia</i> <i>Entamoeba histolytica</i>	Non-specific: associated with systemic infection Hirschsprung's disease Toxin ingestion Primary disaccharidase deficiency
Chronic	0 – 3 mo	3 mo – 3 yr	3 – 18 yr	Uncommon
No FTT	GI infection	GI infection Toddler's diarrhea	GI infection Lactase deficiency Irritable bowel syndrome	Drug-induced Chronic constipation UTI
FTT	Disaccharidase deficiency Cow's milk protein intolerance CF	Celiac disease	IBD Endocrine (thyrotoxicosis, Addison's) Neoplastic (pheochromocytoma, lymphoma)	Short bowel syndrome Schwachman-Diamond syndrome

Gastroenteritis

History

- non-specific: diarrhea, vomiting, fever, anorexia, headache, myalgias, abdominal cramps
- bacterial and parasitic agents more common in older children (2-4 yr)
- recent infectious contacts: symptoms usually begin 24-48 h after exposure

Physical Exam

- febrile
- dehydrated: must assess extent (*see Approach to Infant/Child with Dehydration, P69*)

Investigations

- not usually necessary in young children
- stool analysis: leukocytes/erythrocytes suggests bacterial or parasitic etiology; pH <6 and presence of reducing substances suggests viral etiology

Complications

- viral gastroenteritis usually self-limiting (lasts 3-7 d in most cases)
- adverse effects related to hypovolemia, shock, tissue acidosis, and rapid onset and over-correction of electrolyte imbalances
- death in severe dehydration (rare in developed countries)

Table 15. Gastroenteritis

	Viral Infection	Bacterial Infection
Etiology	Most common cause of gastroenteritis Commonly: rotaviruses (most common), enteric adenovirus, norovirus (typically older children)	<i>Salmonella</i> , <i>Campylobacter</i> , <i>Shigella</i> , pathogenic <i>E. coli</i> , <i>Yersinia</i> , <i>C. difficile</i>
Clinical Presentation	Associated with URIs Resolves in 3-7 d Slight fever, malaise, vomiting, vague abdominal pain	Severe abdominal pain High fever Bloody diarrhea
Risk Factors	Day care, young age, sick contacts, immunocompromised Bacterial infection: travel, poorly cooked meat, poorly refrigerated foods, antibiotics	
Management	Prevention and treatment of dehydration most important (<i>see Dehydration, P69</i>) Early refeeding advisable, with age-appropriate diet upon completion of rehydration Ondansetron for suspected gastroenteritis with mild to moderate dehydration or failed ORT and significant vomiting Antibiotic or antiparasitic therapy when indicated, antidiarrheal medications not indicated Notify Public Health authorities if appropriate Promote regular hand-washing and return to school 24 h after last diarrheal episode to prevent transmission Rotavirus vaccine	

Toddler's Diarrhea

Epidemiology

- most common cause of chronic diarrhea during infancy
- onset between 6-36 mo of age, ceases spontaneously between 2-4 yr

Clinical Presentation

- diagnosis of exclusion in thriving child
- 4-6 bowel movements per day
- diet history (e.g. excess juice intake overwhelms small bowel resulting in disaccharide malabsorption)
- stool may contain undigested food particles
- excoriated diaper rash

Management

- reassurance that it is self-limiting
- 4Fs (adequate Fibre, normal Fluid intake, 35-40% Fat, discourage excess Fruit juice)

Lactase Deficiency (Lactose Intolerance)

Clinical Presentation

- chronic, watery diarrhea and abdominal pain, bloating associated with dairy intake
- primary lactose intolerance: crampy abdominal pain with loose stool (older children, usually of East Asian and African descent)
- secondary lactose intolerance: older infant, persistent diarrhea (decreased lactase production post viral/bacterial infection, celiac disease, or IBD)

Diagnosis

- trial of lactose-free diet
- watery stool, acid pH, positive reducing sugars
- positive breath hydrogen test if >6 yr

Management

- lactose-free diet, soy formula
- lactase-containing tablets/capsules/drops (e.g. Lacteeze®, Lactaid®)

Irritable Bowel Syndrome

- see [Gastroenterology, G23](#)

Celiac Disease

- see [Gastroenterology, G18](#)
- in children: presents at any age, usually 6-24 mo with the introduction of gluten in the diet
- FTT with poor appetite, irritability, apathy, rickets, wasted muscles, flat buttocks, rarely distended abdomen
- GI symptoms: anorexia, N/V, edema, anemia, abdominal pain
- non-GI manifestations: iron-deficiency anemia, dermatitis herpetiformis, dental enamel hypoplasia, osteopenia/osteoporosis, short stature, delayed puberty, behavioural changes
- associated with other autoimmune disorders (e.g. Type 1 diabetes, MS, autoimmune hepatitis)

Celiac disease is associated with an increased prevalence of IgA deficiency. Since tTG is an IgA-detecting test, you must order an accompanying IgA level

A Celiac disease diet must avoid gluten present in **"BROW"** foods
Barley
Rye
Oats (controversial)
Wheat

Milk Allergy (MA) & Cow's Milk Protein Allergy

Pathophysiology

- milk allergy (MA) is IgE mediated whereas cow's milk protein allergy (i.e. food protein induced proctocolitis of infancy (FPIPI) is non-IgE mediated and more common

Clinical Presentation

- MA reactions occur within hours of exposure and are present on the skin (urticarial, pruritus), upper and lower resp tract symptoms (wheeze, cough)
- FPIPI occurs between 2-8 of infancy, presents with:
 - proctocolitis: mild diarrhea, small amounts of bloody stools (common presentation in young infant)
 - enterocolitis: vomiting, diarrhea, anemia, hematochezia, constipation
 - enteropathy: chronic diarrhea, hypoalbuminemia
- up to 50% of children intolerant to cow's milk may be intolerant to soy protein as well

Investigation

- food challenge (gold standard), skin prick test, serum measurement of allergen-specific IgE, patch testing

Management

- MA: stop exposure
- FPIPI: stop, reintroduce milk at 6-8 mo, vast majority (>90%) will outgrow intolerance by 1 yr
- casein hydrolysate formula (dairy-free e.g. Nutramigen®, Pregestimil®) or mother may sequentially remove cow's milk protein, all bovine protein, soy protein, legumes (7 d washout) and continue breastfeeding (with adequate calcium and vit D intake)

Inflammatory Bowel Disease

- see [Gastroenterology, G19](#)

**Cystic Fibrosis**

- see [Respirology, P84](#)

Constipation

- decreased stool frequency (<3 stools/wk) and/or stool fluidity (hard, pellet-like)

FUNCTIONAL CONSTIPATION

- 99% of cases of constipation
- Rome III criteria; ≥ 2 of the following
 - ≤ 2 defecations in the toilet/wk
 - ≥ 1 episode of fecal incontinence/wk
 - history of retentive posturing or excessive volitional stool retention
 - history of painful or hard bowel movements
 - large fecal mass in rectum
 - history of large diameter stools that may obstruct toilet

Pathophysiology

- lack of fibre in diet or change in diet, poor fluid intake, behavioural
 - infants: often occurs when introducing cow's milk after breast milk due to high fat and solute content, lower water content
 - toddlers/older children: can occur during toilet training, or due to pain on defecation, leading to withholding of stool
 - two crucial time periods: toilet training and starting school

Management

- education: explanation of mechanism of functional constipation for parents/older children
- clean out: PEG 3350 flakes (1-1.5 g/kg/d, max 100 g/d), picosalax, PEGlyte®
- maintenance: adequate fluid intake (if <6 mo, 150 mL/kg/d), adequate dietary fibre (fruit, vegetables, whole grains), stool softening (PEG 3350, mineral oil), appropriate toilet training technique (dedicated time for defecation: 3-10 min, 1-2 x/d)
- children should be treated for at least 6 mo, and should not be weaned from maintenance therapy until they are having regular bowel movements without difficulty
- regular follow-up with ongoing support and encouragement is essential

Complications

- pain retention cycle: anal fissures + pain from withholding passing stool, chronic dilatation \pm overflow incontinence

HIRSCHSPRUNG'S DISEASE (Congenital Aganglionic Megacolon)

- see [General Surgery, GS64](#)

**OTHER ORGANIC DISORDERS CAUSING CONSTIPATION**

- endocrine: hypothyroidism, DM, hypercalcemia
- neurologic: spinal cord abnormalities/trauma, NF
- anatomic: bowel obstruction, anus (imperforate, atresia, stenosis, anteriorly displaced)
- drugs: lead, chemotherapy, opioids
- others

Abdominal Pain

ACUTE ABDOMINAL PAIN

History

- description of pain (location, radiation, duration, constant vs. colicky, relation to meals)
- associated symptoms: N/V, diarrhea, fever

Physical Exam

- abdominal exam, rectal exam, rash

Investigations

- CBC, differential, urinalysis to rule out UTI

Table 16. Differential Diagnosis of Acute Abdominal Pain

Gastrointestinal	Hepatobiliary Tract	Genitourinary	Hematologic	Metabolic	Drug and Toxins	Pulmonary	Miscellaneous
Gastroenteritis	Hepatitis	UTI	Sickle cell crisis	Diabetic ketoacidosis	Erythromycin	Pneumonia	Functional pain
Appendicitis	Cholecystitis	Urinary calculi	Henoch-Schönlein purpura	hypoglycemia	salicylates	Diaphragmatic pleurisy	Infantile colic
Mesenteric adenitis	Cholelithiasis	Dysmenorrhea	Hemolytic uremic syndrome	porphyria	lead poisoning		Pharyngitis
Constipation	Spleen – infarction, rupture	Mittelschmerz			venoms		Angioneurotic edema
Ileus	Pancreatitis	PID					Mediterranean fever
Abdominal trauma		Threatened abortion					
Intestinal obstruction (incarcerated hernia, intussusception, volvulus)		Ectopic pregnancy					
Peritonitis		Nephrolithiasis					
Peptic ulcer		Testicular torsion					
Meckel's diverticulum		Ovarian torsion					
IBS		Endometriosis					
Food poisoning		Hematocolpos					
Lactose intolerance							

APPENDICITIS

- see [General Surgery, GS27](#)
- most common cause of acute abdomen after 5 yr of age
- clinical features: low grade fever, abdominal pain, anorexia, N/V (after onset of pain), peritoneal signs (generalized peritonitis is a common presentation in infants/young children)
- treatment: surgical
- complications: perforation (common in young children), abscess

INTUSSUSCEPTION

- telescoping of segment of bowel into distal segment causing ischemia and necrosis

Epidemiology

- 90% idiopathic, children with CF or GJ tube at significantly increased risk; M:F = 3:1
- 50% between 3-12 mo, 75% before 2 yr of age

Pathophysiology

- usual site: ileocecal junction; jejunum in children with GJ tubes
- lead point of telescoping segment may be swollen Peyer's patches, Meckel's diverticulum, polyp, malignancy, HSP, structural abnormalities

Clinical Presentation

- "classic triad" (<25% patients) - abdominal pain, palpable mass, red currant jelly stools
- often preceded by URTI
- sudden onset of recurrent, paroxysmal, severe periumbilical pain with pain-free intervals
- later vomiting (may be bilious) and rectal bleeding (late finding)
- shock and dehydration; lethargy may be only presenting symptom

Diagnosis

- U/S, air enema

Management

- air enema can be therapeutic (reduces intussusception in 75% of cases), reduction under hydrostatic pressure, surgery rarely needed
- recurrence rate 10-15%, need to consider pathologic lead point

Intussusception – Classic Triad

- Abdominal pain
- Palpable mass
- Red currant jelly stools

Chronic Abdominal Pain

Epidemiology

- prevalence: 10% of school children (peak at 8-10 yr), F>M

Etiology

- organic (<10%)
 - gastrointestinal
 - constipation (cause vs. effect), infectious
 - IBD, esophagitis, peptic ulcer disease, lactose intolerance
 - anatomic anomalies, masses
 - pancreatic, hepatobiliary
 - celiac disease
 - genitourinary causes: recurrent UTI, nephrolithiasis, chronic PID, Mittelschmerz
 - neoplastic
- functional abdominal pain (90%): can be diagnosed when there are no alarming signs or symptoms, physical exam is normal, and stool sample tests are negative for occult blood; no further testing is required, unless high suspicion for organic cause
 - alarming symptoms include involuntary weight loss, deceleration of linear growth, GI blood loss, significant vomiting, chronic severe diarrhea, persistent upper or right lower quadrant pain, unexplained fever, family history of IBD
 - can be further subclassified into functional dyspepsia (pain in upper abdomen), irritable bowel syndrome (alternating bowel movements), abdominal migraine (paroxysmal abdominal pain, associated with anorexia, nausea, vomiting, pallor), functional abdominal pain syndrome

Clinical Presentation

- clustering episodes of vague, crampy periumbilical/epigastric pain, vivid pain description
- seldom awakens child from sleep, less common on weekends
- aggravated by exercise, alleviated by rest
- psychological factors related to onset and/or maintenance of pain, school avoidance
- psychiatric comorbidity: anxiety, somatoform, mood, learning disorders, sexual abuse, eating disorders, elimination disorders
- diagnosis of exclusion

Investigations

- fecal occult blood and others based on clinical suspicion (CBC, ESR, urinalysis, etc.)

Management

- continue to attend school
- manage any emotional or family problems, counselling, CBT
- trial of high fibre diet, trial of lactose-free diet
 - medication should be for symptom relief – acid reduction therapy for dyspepsia, antispasmodic agents, smooth muscle relaxants for pain, nonstimulating laxatives or antidiarrheals for altered bowel pattern
- possible role for amitriptyline
- reassurance

Prognosis

- pain resolves in 30-50% of children within 2-6 wk of diagnosis
- 30-50% of children with functional abdominal pain have functional pain as adults (e.g. IBS)

Chronic Abdominal Pain

Rule of 3s

- 3 episodes of severe pain
- Child > 3 yr old
- Over 3 mo period

Red Flags for Organic Etiology of Chronic Abdominal Pain

- Age <5 yr old
- Fever
- Localizes pain away from midline
- Anemia
- Evidence of GI blood loss
- Rash
- Pain awakens child at night
- Travel history
- Prominent vomiting, diarrhea
- Weight loss or failure to gain weight
- Deceleration in linear growth
- Joint pain
- Family history of IBD
- Abnormal or unexplained physical exam findings

Abdominal Mass

Table 17. Differential Diagnosis for Abdominal Mass

	Benign	Malignant
Renal (note: 50% of abdominal masses in newborn are renal in origin)	Hydronephrosis Polycystic kidney disease Hamartoma	Nephroblastoma (Wilms' tumour) Renal cell carcinoma
Adrenal		Neuroblastoma
Ovarian	Ovarian cysts	Ovarian tumours
Other	Hepatomegaly/splenomegaly Pyloric stenosis Abdominal hernia Teratoma Fecal impaction	Lymphoma Rhabdomyosarcoma Retroperitoneal sarcoma

Upper Gastrointestinal Bleeding

- see [Gastroenterology, G25](#)

Lower Gastrointestinal Bleeding

- see [Gastroenterology, G27](#)

Etiology

- acute
 - infectious (bacterial, parasitic)
 - antibiotic-induced (*C. difficile*)
 - NEC in preterm infants
 - anatomic
 - malrotation/volvulus, intussusception
 - Meckel's diverticulitis
 - anal fissures, hemorrhoids
 - vascular/hematologic
 - HSP
 - HUS
 - coagulopathy
- chronic
 - anal fissures (most common)
 - colitis
 - IBD
 - allergic (milk protein)
 - structural
 - polyps (most are hamartomas)
 - neoplasms (rare)
 - coagulopathy

Physical Exam

- hemodynamic status, evidence of FTT, fever
- anal and rectal exam: tags, fissures, anal fistulas, polyps, foreign body, blood per rectum
- stool appearance
- NG aspirate
- lower GI bleed may present as melena (if it involves the small bowel) or hematochezia

Investigations

- stool cultures (C&S, *C. difficile* toxin)
- urinalysis and microscopy
- CBC, smear, differential, ESR, CRP, electrolytes, urea, Cr, INR, PTT, albumin, iron studies, amoeba titers
- radiologic investigations (including abdominal x-ray to rule out obstruction)
- Meckel's radionuclide scan

Management

- acute stabilization: ABCs, volume and blood replacement, bowel rest (NPO, NG tube)
- once stable, endoscopy and/or surgery as indicated

Genetics, Dysmorphisms, and Metabolism

- see [Medical Genetics](#)

Hematology

Approach to Anemia

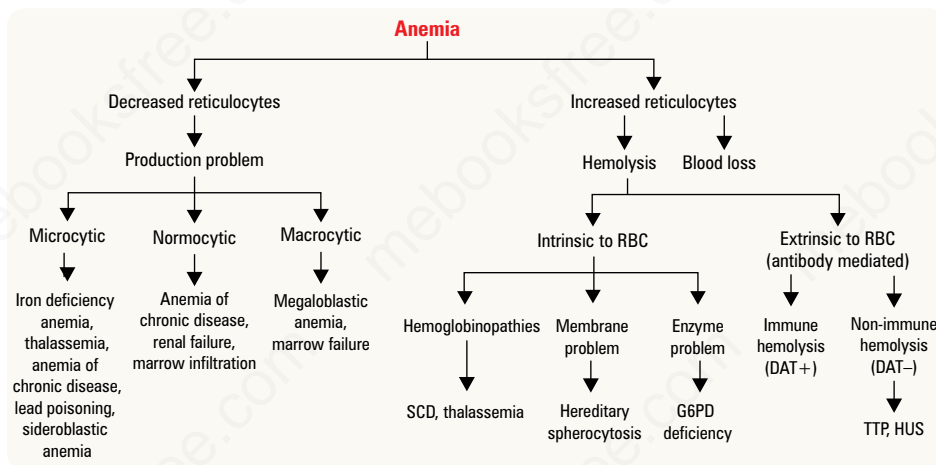

Figure 9. Approach to anemia

Physiologic Anemia

- high Hb (>170 g/L) and reticulocyte count at birth is caused by a hypoxic environment in utero
- after birth, levels start to fall due to shorter fetal RBC lifespan, decreased RBC production (during first 6-8 wk of life, there is virtually no erythropoiesis due to new O₂ rich environment), and increasing blood volume secondary to growth
- lowest levels about 100 g/L at 8-12 wk age (earlier and more exaggerated in premature infants); levels rise spontaneously with activation of erythropoiesis
- usually no treatment required

Iron Deficiency Anemia

- most common cause of childhood anemia
- full term infants exhaust iron reserves by 6 mo of age
- premature infants have lower reserves, therefore exhausted by 2-3 mo of age
- common diagnosis between 6 mo-3 yr and 11-17 yr due to periods of rapid growth and increased iron requirements; adolescents also have poor diet and menstrual losses

Etiology

- children at risk (premature, LBW, low SES, etc.)
- dietary risk factors: whole cow milk in first year of life
- age >6 mo: <2 servings/d of iron-fortified cereal, red meat, or legumes
- age <12 mo: use of low-iron formula (<10 mg/L), primary diet of cow, goat, or soy milk
- age 1-5 yr: >16-20 oz/d of non-fortified milk
- blood loss
 - iatrogenic: repeated blood sampling (especially in hospitalized neonates)
 - allergic: cow's milk protein-induced colitis

Clinical Manifestation

- usually asymptomatic until marked anemia. Symptoms may include: pallor, fatigue, pica (eating non-food materials), tachycardia, systolic murmur, angular cheilitis, koilonychia (spoon nails)

Investigations

- CBC: low Hb, MCV, and MCH, reticulocyte count normal or high (absolute number low)
- Mentzer index (MCV/RBC) can help distinguish iron deficiency anemia from thalassemia
 - ratio <13 suggests thalassemia
 - ratio >13 suggests iron deficiency
- blood smear: hypochromic, microcytic RBCs, pencil shaped cells, poikilocytosis
- iron studies: low ferritin, other (low iron, high total iron binding capacity, high transferrin, low transferrin saturation)
- initial therapy: trial of iron

Prevention

- breastfed term infants: begin iron supplementation (1 mg/kg/d) at 4-6 mo, continuing until able to eat ≥2 feeds/d of iron-rich foods
- non-breastfed (<50% of diet) term infants: give iron-fortified formula from birth
- premature infants: give iron supplements from 1 mo through to 1 yr of age
- no cow's milk until 9-12 mo, early introduction of red meat and iron-rich vegetables: total daily iron should be 11 mg (age 6-12 mo), 7 mg (age 1-3 yr)
- universal screening of Hb levels recommended at 9 mo

Management

- encourage diverse, balanced diet, limit homogenized milk to 16-20 oz/d
- oral iron therapy: 4-6 mg/kg/d elemental iron, divided bid to tid, for 3 mo
 - increased reticulocyte count in 2-3 d (peaks day 5-7)
 - increased hemoglobin in 4-30 d
 - repletion of iron stores in 1-3 mo
 - repeat hemoglobin levels after 1 mo of treatment
- poor response to oral iron therapy: non-adherence, medication intolerance, ongoing blood loss, IBD, celiac disease, incorrect diagnosis

Complications

- can cause irreversible effects on development if untreated (behavioural and intellectual deficiencies)
- angular cheilitis, glossitis, koilonychia (spoon nails)

Normal Hb Values by Age

Age	Hb Range (g/L)
Newborn	137-201
2 wk	130-200
3 mo	95-145
6 mo-6 yr	105-140
7-12 yr	110-160
Adult female	120-160
Adult male	140-180

MCV in childhood varies with age
Rule of thumb: lower normal limit of MCV = 70 + age (yr) until 80 fL (adult standard)

Ferritin is an acute phase reactant, therefore, normal or high ferritin does not exclude iron deficiency anemia during an infection

Iron deficiency is rare in children <6 mo in the absence of blood loss or prematurity

Vitamin K Deficiency

Etiology

- hemorrhagic disease of the newborn due to relative deficiencies of vitamin K-dependent coagulation factors
 - generalized bleeding: GI/intracranial hemorrhage
- IM injection at birth, can also be given orally (3 doses: at birth, 2-4 wk, 6-8 wk) but infants at higher risk of HDNB
- reason for administration at birth:
 - human milk contains small amounts of vitamin K, and infants require ingestion of large volumes of human milk to promote GI bacterial colonization
 - until few days after birth, susceptible to vitamin K deficiency

Anemia of Chronic Disease

- see [Hematology, H13](#)

Sickle Cell Disease

- see [Hematology, H20](#)

Thalassemia

- see [Hematology, H18](#)

Hereditary Spherocytosis

- see [Hematology, H22](#)

Glucose-6-Phosphate Dehydrogenase Deficiency

- see [Hematology, H23](#)

G6PD deficiency protects against parasitism of RBCs (i.e. malaria)

Bleeding Disorders

- see [Hematology, H27](#)

Table 18. Evaluation of Abnormal Bruising/Bleeding

	PFA	PT	PTT	VIII:C	vWF	Platelets	Fibrinogen
Hemophilia A	N	N	↑	↓	N	N	N
Hemophilia B	N	N	↑	N	N	N	N
von Willebrand Disease	↑	N	N or ↑	↓	N or ↓	N	N
DIC	N or ↑	↑	↑	↓	N	↓	↓
Vitamin K Deficiency	N	↑	↑	N	N	N	N
Thrombocytopenia	↑	N	N	N	N	↓	N

DIC = disseminated intravascular coagulation; PFA = platelet function assay; VIII:C = Factor VIII coagulant activity; vWF = von Willebrand Factor

Extensive bruising in the absence of lab abnormalities: consider child maltreatment

Immune Thrombocytopenic Purpura

Epidemiology

- most common cause of thrombocytopenia in childhood
- peak age: 2-6 yr, M=F
- incidence 5:100,000 children per year

Etiology

- caused by autoantibodies that bind to platelet membranes → Fc-receptor mediated splenic uptake → destruction of platelets

Clinical Presentation

- 50% present 1-3 wk after viral illness (e.g. URTI, chicken pox)
- sudden onset of petechiae, purpura, epistaxis in an otherwise well child
- clinically significant bleed in only 3% (severe bleed more likely with platelet count <10) with <0.5% risk of intracranial bleed
- no lymphadenopathy, no hepatosplenomegaly
- labs: thrombocytopenia with normal RBC, WBC
- bone marrow aspirate only if atypical presentation (≥ 1 cell line abnormal, hepatosplenomegaly)
- differential diagnosis: leukemia, drug-induced thrombocytopenia, HIV, infection (viral), autoimmune (SLE, ALPS)

Management

- observation vs. pharmacologic intervention highly debated; spontaneous recovery in >70% of cases within 3 mo
- treatment with IVIg or prednisone if mucosal or internal bleeding, platelets <10, or at risk of significant bleeding (surgery, dental procedure, concomitant vasculitis or coagulopathy)
- life-threatening bleed: additional platelet transfusion \pm emergency splenectomy
- persistent (>3-12 mo) or chronic (>12 mo): re-evaluate; treat if symptoms persist
- supportive: avoid contact sports and ASA/NSAIDs

The American Society of Hematology 2011 Evidence-Based Practice Guideline for Immune Thrombocytopenia

Blood 2011;117(16):4190-207

Recommendations

- Bone marrow examination is unnecessary in children and adolescents with the typical features of ITP.
- Bone marrow examination is not necessary in children who fail IVIg therapy (grade 1B).
- Children with no bleeding or mild bleeding (defined as skin manifestations only, such as bruising and petechiae) may be managed with observation alone regardless of platelet count.
- For pediatric patients requiring treatment, a single dose of IVIg (0.8-1 g/kg) or a short course of corticosteroids may be used as first-line treatment.
- IVIg can be used if a more rapid increase in the platelet count is desired.
- Anti-D therapy is not advised in children with a hemoglobin concentration that is decreased due to bleeding, or with evidence of autoimmune hemolysis.

Suggestions

- Bone marrow examination is also not necessary in similar patients prior to initiation of treatment with corticosteroids or before splenectomy.
- Testing for antinuclear antibodies is not necessary in the evaluation of children and adolescents with suspected ITP.
- A single dose of anti-D can be used as first-line treatment in Rh-positive, non-splenectomized children requiring treatment.

Hemophilia

- see [Hematology, H31](#)

von Willebrand's Disease

- see [Hematology, H30](#)

Oncology

- cancer is the second most common cause of death after injuries in children >1 yr of age
- cause is rarely known, but increased risk for children with: chromosomal syndromes (e.g. Trisomy 21), cancer predisposition syndromes (e.g. Li-Fraumeni syndrome), prior malignancies, neurocutaneous syndromes, immunodeficiency syndromes, family history, exposure to radiation, chemicals, biologic agents
- leukemias are the most common type of pediatric malignancy (30%) followed by brain tumours (25%), and lymphomas (15%)
- some malignancies are more prevalent in certain age groups
 - newborns: neuroblastoma, Wilms' tumour, retinoblastoma
 - infancy and childhood: leukemia, neuroblastoma, CNS tumours, Wilms' tumour, retinoblastoma
 - adolescence: lymphoma, gonadal tumours, germ cell tumours, bone tumours
- unique treatment considerations in pediatrics because radiation, chemotherapy, and surgery can impact growth and development, endocrine function, and fertility
- good prognosis: treatments have led to remarkable improvements in overall survival and cure rates for many pediatric cancers (>80%)

Lymphadenopathy

Clinical Presentations

- features of malignant lymphadenopathy: firm, discrete, non-tender, enlarging, immobile \pm suspicious mass/imaging findings \pm constitutional symptoms
- fluctuance, warmth, or tenderness are more suggestive of benign nodes (infection)

Differential Diagnosis

- infection
 - viral: URTI, EBV, CMV, adenovirus, HIV
 - bacterial: *S. aureus*, GAS, anaerobes, *Mycobacterium* (e.g. TB), cat scratch disease (*Bartonella*)
 - other: fungal, protozoan, *Rickettsia*
- autoimmune: rheumatoid arthritis, SLE, serum sickness
- malignancy: lymphoma, leukemia, metastatic solid tumours
- storage diseases: Niemann-Pick, Gaucher's
- other: sarcoidosis, Kawasaki disease, histiocytoses

Investigations

- generalized lymphadenopathy
 - CBC and differential, blood culture
 - uric acid, LDH
 - ANA, RF, ESR
 - EBV/CMV/HIV serology
 - toxoplasma titre
 - fungal serology
 - CXR
 - TB tests
 - biopsy
- regional lymphadenopathy
 - period of observation if asymptomatic
 - trial of oral antibiotics
 - ultrasound
 - biopsy (especially if persistent >6 wk and/or constitutional symptoms)

Most common cause of acute bilateral cervical LAD is viral illness

Leukemia

- see [Hematology, H37](#)

Epidemiology

- mean age of diagnosis 2-5 yr but can occur at any age
- heterogeneous group of diseases
 - ALL (80%)
 - AML (15%)
 - CML (<5%)
- children with DS are 15x more likely to develop leukemia

Clinical Presentation

- infiltration of leukemic cells into bone marrow results in bone pain and bone marrow failure (anemia, neutropenia, thrombocytopenia)
- infiltration into tissues results in lymphadenopathy, hepatosplenomegaly, CNS manifestations, testicular disease
- fever, fatigue, weight loss, bruising, and easy bleeding
- hyperleukocytosis (total WBC >100 x 10⁹/L) is a medical emergency
 - presents clinically with respiratory or neurological distress caused by hyperviscosity of blood and leukostasis
 - risk of ICH, pulmonary leukostasis syndrome, tumour lysis syndrome
 - management: fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)

Management

- fluids, allopurinol/rasburicase, fresh frozen plasma/platelets to correct thrombocytopenia, induction chemotherapy, avoid transfusing RBCs unless symptomatic (and then use very small volumes)
- combination chemotherapy using non-cross resistant chemotherapy agents, allogeneic stem cell transplantation for high-grade or recurrent disease
- supportive care and management of treatment complications
 - febrile neutropenia: see [Infectious Diseases, ID45](#)
 - tumour lysis syndrome: see [Hematology, H52](#)

Prognosis

- 80-90% 5 yr event-free survival for ALL, 50-60% 5-yr survival for AML
- patients are stratified into standard risk and high risk based on WBC and age; other prognostic factors include presence of CNS/testicular disease, immunophenotype, cytogenetics, and initial response to therapy (most important prognostic variable)

Lymphoma

- see [Hematology, H45](#)

Epidemiology

- Hodgkin lymphoma: incidence is bimodal, peaks at ages 15-34 and >50 yr old
- non-Hodgkin lymphoma: incidence peaks at 7-11 yr

Clinical Presentation

- Hodgkin lymphoma
 - most common presentation is persistent, painless, firm, cervical or supraclavicular lymphadenopathy
 - can present as persistent cough or dyspnea (secondary to mediastinal mass) or less commonly as splenomegaly, axillary, or inguinal lymphadenopathy
 - constitutional symptoms in 30% of children
 - lymph nodes become sequentially involved as disease spreads

Back pain in children must always be investigated!
Unlike adults, back pain in children often points to a pathological process

- non-Hodgkin lymphoma
 - generally categorized into lymphoblastic, large cell, and Burkitt's/Burkitt's-like lymphoma
 - rapidly growing tumour with distant metastases (unlike adult non-Hodgkin lymphoma)
 - signs and symptoms related to disease site: most commonly abdomen, chest (mediastinal mass), head and neck region

Management

- Hodgkin lymphoma
 - combination chemotherapy and radiation
 - aimed at limiting cumulative doses of anthracyclines (toxic to heart) and alkylators (risk of second malignancy, infertility) and limiting dose and field of radiation
 - increasing role for use of PET scanning to assess early disease response and plan therapy
- non-Hodgkin lymphoma
 - combination chemotherapy
 - no added benefit of radiation in pediatric protocols

Constitutional symptoms = fever, chills, night sweats, unexplained weight loss

Prognosis

- Hodgkin lymphoma: >90% 5 yr survival
- non-Hodgkin lymphoma: 75-90% 5 yr survival

Brain Tumours

- see [Neurosurgery, NS11](#)

Wilms' Tumour (Nephroblastoma)

Epidemiology

- usually diagnosed between 2-5 yr; M=F
 - most common primary renal neoplasm of childhood
 - 5-10% of cases both kidneys are affected (simultaneously or in sequence)

Differential Diagnosis

- hydronephrosis, polycystic kidney disease, renal cell carcinoma, neuroblastoma

Clinical Presentation

- 80% present with asymptomatic, unilateral abdominal mass
- may also present with HTN, gross hematuria, abdominal pain, vomiting
- may have pulmonary metastases at time of diagnosis (respiratory symptoms)

Associated Congenital Abnormalities

- WAGR syndrome (Wilms' tumour, Aniridia, Genital anomalies, mental Retardation) with 11p13 deletion
- Beckwith-Wiedemann syndrome:
 - characterized by enlargement of body organs (especially tongue), hemihypertrophy, renal medullary cysts, and adrenal cytomegaly
 - also at increased risk for developing hepatoblastoma, and less commonly adrenocortical tumours, neuroblastomas, and rhabdomyosarcomas
- Denys-Drash syndrome: characterized by gonadal dysgenesis and nephropathy leading to renal failure

Management

- staging ± nephrectomy
- chemotherapy, radiation for higher stages

Prognosis

- 90% long-term survival

Neuroblastoma

Epidemiology

- most common cancer occurring in first year of life
- neural crest cell tumour arising from sympathetic tissues (neuroblasts)

Clinical Presentation

- can originate from any site in sympathetic nervous system, presenting as mass in neck, chest, or abdomen (most common site is adrenal gland)
- signs and symptoms of disease vary with location of tumour
 - thoracic: dyspnea, Horner's syndrome
 - abdomen: palpable mass
 - spinal cord compression

- metastases are common at presentation (>50% present with advanced stage disease):
 - usually to bone or bone marrow (presents as bone pain, limp)
 - can also present with periorbital ecchymoses, abdominal pain, emesis, fever, weight loss, anorexia, hepatomegaly, "blueberry muffin" skin nodules
- paraneoplastic: HTN, palpitations, sweating (from excessive catecholamines), diarrhea, FTT (from vasoactive intestinal peptide secretion), opsomyoclonus

Management

- depends on prognostic factors and may include combination of: surgery, radiation, chemotherapy, autologous stem cell transplantation, immunotherapy

Prognosis

- prognosis is often poor due to late detection
- good prognostic factors
 - "age and stage" are important determinants of better outcome: <18 mo, stage I, II, IV-S disease ("S" designates a "Special" classification only pertaining to infants)
 - primary site: posterior mediastinum and neck
 - low serum ferritin
 - more differentiated histology
 - tumour cell markers: aneuploidy; absent *MYCN* oncogene amplification

Bone Tumours

- see [Orthopedics, OR45](#)

Cancer Predisposition Syndromes

- suspected in cases of multiple primary neoplasms, especially early onset for cancer type and/or family history consistent with known cancer predisposition syndrome (critical to obtain family history and refer if syndrome suspected)
- cancer predisposition syndromes with pediatric onset include Li-Fraumeni syndrome (soft tissue sarcomas, osteosarcoma, CNS tumours and adrenal cortical carcinoma), hereditary retinoblastoma and Fanconi anemia (leukemias)

Infectious Diseases

Fever

Definition

- fever: a practical definition is >38°C/100.4°F oral or rectal
- fever without a source/focus: acute febrile illness (typically <10 d duration) with no cause of fever even after careful history and physical
- fever of unknown origin: daily or intermittent fevers for at least 2 consecutive wk of uncertain cause after careful history and physical, and initial laboratory assessment

Etiology

- infectious: anatomic approach (CNS, ears, upper and lower respiratory tract, GI, GU, skin, soft tissue, bones and joints, etc.)
- inflammatory: mainly autoimmune (Kawasaki disease, JIA, IBD, SLE, etc.)
- malignancy: childhood cancers (leukemia, lymphoma, neuroblastoma, etc.)
- miscellaneous: dehydration, drugs and toxins, post-immunization, familial dysautonomia, factitious disorder, etc.

Diagnosis

- history: duration, height and pattern of fever, associated symptoms, exposures, constitutional symptoms, recent antipyretic use, ethnic or genetic background, day care, sick contacts, travel, tick bites, age of child
- physical exam: toxic vs. non-toxic, vitals, growth, complete exams of the skin, HEENT, chest, abdomen, lymph nodes, genitalia
- investigations: guided by history, physical exam, and clinical suspicion

Evaluation of Neonates and Infants with Fever

- several protocols exist that attempt to identify neonates and young infants at low risk of serious bacterial infection (e.g. Rochester Criteria)
 - such protocols are not as sensitive in the 1-28 d age group; therefore, febrile neonates should be considered high risk regardless of clinical presentation and laboratory findings

Management

- admit to hospital if appropriate
- treat the source if known
- replace fluid losses (e.g. from vomiting, diarrhea, etc.); maintenance fluid needs are higher in febrile child
- reassure parents that most fevers are benign and self-limited
- antipyretics (acetaminophen and/or ibuprofen) are not necessary in most cases, but can be given if child is uncomfortable

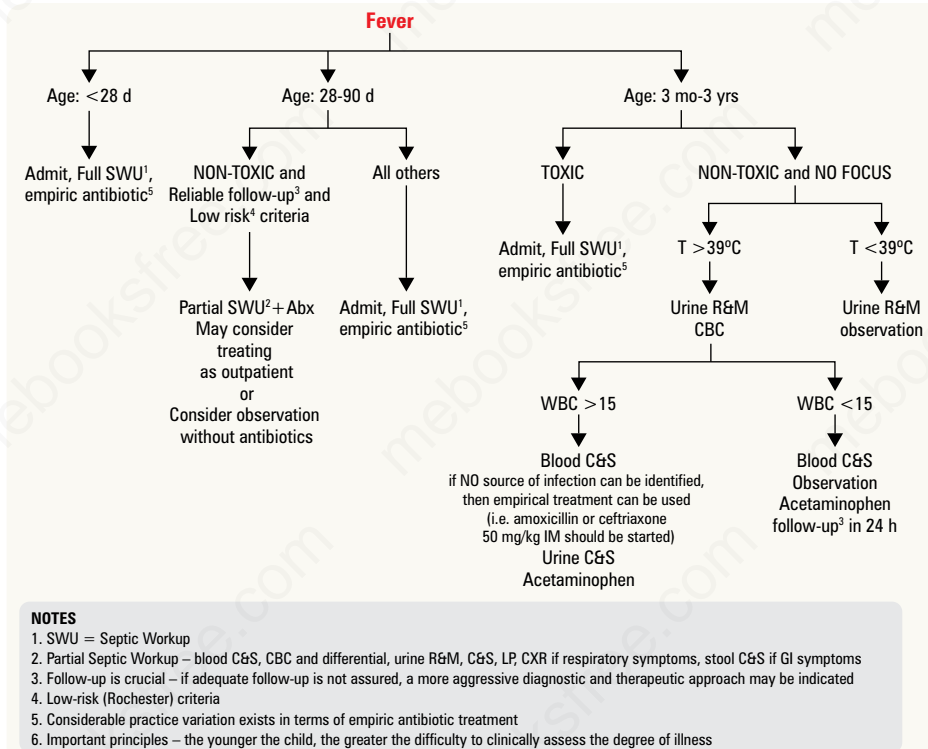

Figure 10. Approach to the febrile child

Acute Otitis Media

All of:

1. presence of middle ear effusion
2. presence of middle ear inflammation
3. acute onset of symptoms of middle ear effusion and inflammation

Epidemiology

- 60-70% of children have at least 1 episode of AOM before 3 yr of age
- 18 mo-6 yr most common age group
 - 22% of children in this age range will develop AOM in the first wk of a viral URI
- one third of children have had ≥ 3 episodes by age 3; peak incidence January to April

Etiology

- *S. pneumoniae*: 32% of cases (decreasing since the introduction of PCV7 and PCV 13)
 - *H. influenzae* (non-typeable): >50% of refractory AOM
- *M. catarrhalis*: 14% of cases – less virulent
- GAS
- viral – more likely to spontaneously resolve
- less common – anaerobes (newborns), Gram-negative enterics (infants)

Predisposing Factors

- Eustachian tube dysfunction/obstruction
 - swelling of tubal mucosa: URTI, allergic rhinitis, chronic rhinosinusitis
 - obstruction/infiltration of Eustachian tube ostium: adenoid hypertrophy (not due to obstruction but by maintaining a source of infection), barotrauma (sudden changes in air pressure)
 - inadequate tensor palatini function: cleft palate (even after repair)
- abnormal Eustachian tube: genetic syndromes such as DS, Crouzon, Apert
- disruption of action of cilia of Eustachian tube: Kartagener's syndrome, CF
- immunosuppression/deficiency due to chemotherapy, steroids, DM, hypogammaglobulinemia, CF

Rochester Criteria – Developed to Identify Infants ≤ 60 d of Age with Fever at Low Risk of Serious Bacterial Infection

Clinically	Well
WBC Count	5-15 $\times 10^9/L$
Bands	<1.5 $\times 10^9/L$
Urinalysis	<10 WBC/HPF
Stool (if diarrhea)	<5 WBC/HPF
Past Health	Born >37 wk Home with/before mom No hospitalizations No prior antibiotic use No prior treatment for unexplained hyperbilirubinemia No chronic disease

Clinical Assessment of AOM in Pediatrics JAMA 2010;304:2161-2169

Purpose: To summarize the evidence on AOM diagnosis, treatment and the association of the heptavalent pneumococcal conjugate vaccine (PCV7) use with AOM microbiology.

Methods: Systematic review of diagnostic studies with a criterion standard, observational studies, and RCTs comparing AOM microbiology with and without PCV7, and RCTs assessing antibiotic treatment.

Results: 135 studies were included. Otitoscopic findings of tympanic membrane bulging (positive likelihood ratio (PLR) 51, 95% CI 36-73) and redness (PLR 8.4, 7-11) were associated with accurate diagnosis. Prevalence of *S. pneumoniae* decreased while that of *H. influenzae* increased pre vs. post-PCV7. Clinical success was higher with immediate ampicillin or amoxicillin versus placebo (73% vs. 60%; pooled rate difference 12%, 95% CI 5-18%; NNT 9, 95% CI 6-20). The risk of rash or diarrhea was increased by 3 to 5%. Some evidence suggested greater success with immediate versus delayed antibiotics. No significant differences were seen in terms of comparative effectiveness of antibiotics.

Conclusion: Otitoscopic findings are critical to accurate AOM diagnosis. Antibiotics are somewhat more effective than no treatment despite a higher incidence of adverse effects, and generally are comparatively equal in effectiveness.

Risk Factors

- prolonged bottle feeding, while laying down and/or shorter duration of breast feeding
 - pacifier use
- second-hand smoke
- crowded living conditions (day care/group child care facilities) or sick contacts
- family history of otitis media
- orofacial abnormalities
- immunodeficiency
- ethnicity – First Nations and Inuit
 - for recurrent AOM: lower levels of secretory IgA or persistent biofilms in the middle ear

Pathogenesis

- obstruction of Eustachian tube → air absorbed in middle ear → negative pressure (an irritant to middle ear mucosa) → edema of mucosa with exudate/effusion → infection of exudate from nasopharyngeal secretions

Clinical Features

- triad of otalgia, fever (especially in younger children), and conductive hearing loss
- rarely tinnitus, vertigo, and/or facial nerve paralysis
- otorrhea if tympanic membrane perforated
- infants/toddlers: ear-tugging (this alone is not a good indicator of pathology), hearing loss, balance disturbances (rare), irritable, poor sleeping, vomiting and diarrhea, anorexia
- otoscopy of TM: hyperemia, bulging, pus may be seen behind TM, loss of landmarks (e.g. handle and long process of malleus not visible)

Diagnosis

- most important criteria for AOM is a bulging TM (all children with bulging TM had AOM and only 8% of children with non-bulging TM had AOM) – Reference: Shaikh N, Hoberman A, Rockette HE, Kurs-Lasky M 2012

Management

- 1st line
 - amoxicillin 75-90 mg/kg/d divided into two doses: safe, effective, and inexpensive. Use high doses to overcome MIC for penicillin binding proteins (method of resistance)
 - if penicillin allergic: macrolide (clarithromycin, azithromycin – high resistance), trimethoprim-sulphamethoxazole (Bactrim®)
- 2nd line
 - amoxicillin-clavulanic acid (Clavulin®)
 - cephalosporins: cefuroxime axetil (Ceftin®), ceftriaxone (Rocephin®), cefaclor (Ceclor®), cefixime (Suprax®)
 - AOM deemed unresponsive if clinical signs/symptoms and otoscopic findings persist beyond 48 h of antibiotic treatment
 - use second line treatment for otitis-conjunctivitis syndrome (AOM with bacterial conjunctivitis) because *H. influenzae* and *M. catarrhalis* are more likely pathogens which are Beta lactamase producing, so Amoxil is ineffective
- symptomatic therapy: antipyretics/analgesics (e.g. acetaminophen), decongestants (may relieve nasal congestion but does not treat AOM)
- prevention: parent education about risk factors, pneumococcal and influenza vaccines, surgery (e.g. tympanostomy tubes)
 - choice of surgical therapy for recurrent AOM depends on whether local factors (Eustachian tube dysfunction) are responsible (use ventilation tubes), or regional disease factors (tonsillitis, adenoid hypertrophy, sinusitis) are responsible

Complications

- extracranial: hearing loss and speech delay (secondary to persistent middle ear effusion), TM perforation, extension of suppurative process to adjacent structures (mastoiditis, petrositis, labyrinthitis), cholesteatoma, facial nerve palsy, middle ear atelectasis, ossicular necrosis, vestibular dysfunction
- intracranial: meningitis, epidural and brain abscess, subdural empyema, lateral and cavernous sinus thrombosis, carotid artery thrombosis

The Diagnosis and Management of Acute Otitis Media

Pediatrics 2013;131:e964-e999

Recommendations

- Management of AOM should include an assessment of pain; if pain is present, the clinician should recommend treatment to reduce pain.
- Prescribe antibiotic therapy for AOM (bilateral or unilateral) in children 6 mo and older with severe signs or symptoms (i.e. moderate or severe otalgia or otalgia for at least 48 h or temperature 39°C [102.2°F] or higher).
- For bilateral or unilateral AOM in children 6 mo through 23 mo of age without severe signs or symptoms (i.e. mild otalgia for less than 48 h and temperature less than 39°C [102.2°F]) either prescribe antibiotic therapy or offer observation with close follow-up based on joint decision-making with the parent(s)/caregiver(s). With observation ensure follow-up and begin antibiotic therapy if the child worsens or fails to improve within 48-72 h of onset of symptoms.
- Do NOT prescribe prophylactic antibiotics to reduce the frequency of episodes of AOM in children with recurrent AOM.
- Recommend annual influenza vaccine and pneumococcal conjugate vaccine to all children according to vaccination schedule.

Option

- Offer tympanostomy tubes for recurrent AOM (3 episodes in 6 mo or 4 episodes in 1 yr with 1 episode in the preceding 6 mo).

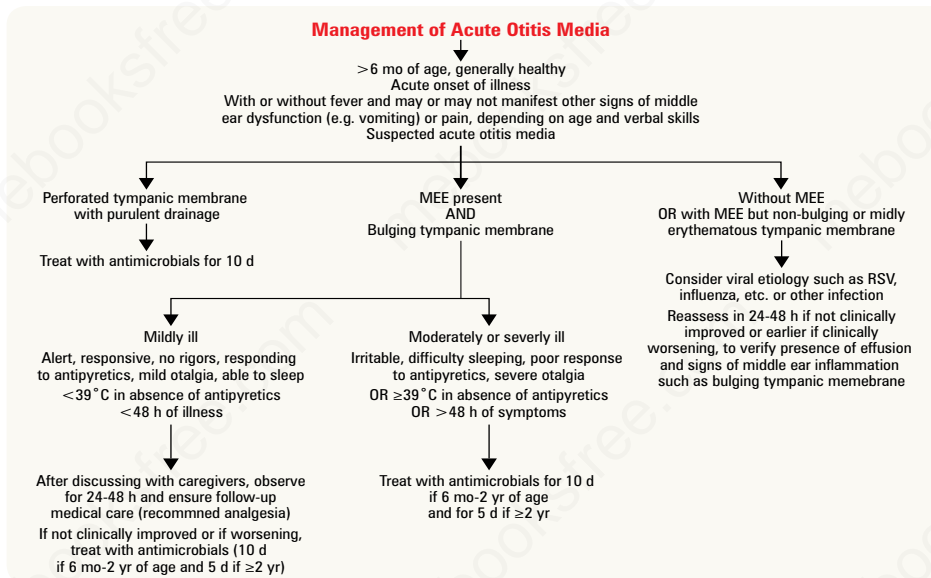

Figure 11. Management of acute otitis media

Flow diagram for the management of children with suspected and confirmed acute otitis media – from CPS statement Feb 2016

Otitis Media with Effusion

Definition

- presence of fluid in the middle ear without signs or symptoms of ear infection

Epidemiology

- most common cause of pediatric hearing loss
- not exclusively a pediatric disease
- follows AOM frequently in children
- middle ear effusions have been shown to persist following an episode of AOM for 1 mo in 40% of children, 2 mo in 20%, and >3 mo in 10%

Risk Factors

- same as AOM

Clinical Features

- conductive hearing loss ± tinnitus
- fullness – blocked ear
- ± pain, low grade fever
- otoscopy of TM
 - discolouration – amber or dull grey
 - meniscus fluid level behind TM
 - air bubbles
 - retraction pockets/TM atelectasis
 - flat tympanogram
 - most reliable finding with pneumatic otoscopy is immobility

Treatment

- expectant: 90% resolve by 3 mo
- document hearing loss with audiogram (see [Otolaryngology Figure 16B](#) and [Figure 17B, OT10-11](#))
- no statistical proof that antihistamines, decongestants, antibiotics clear disease faster
- surgery: myringotomy ± ventilation tubes ± adenoidectomy (if enlarged or on insertion of second set of tubes after first set falls out)
- ventilation tubes to equalize pressure and drain ear

Complications of OME

- hearing loss, speech delay, learning problems in young children
- chronic mastoiditis
- ossicular erosion
- cholesteatoma especially when retraction pockets involve pars flaccida
- retraction of tympanic membrane, atelectasis, ossicular fixation

Gastroenteritis

- see [Gastroenterology, P34](#)

HIV Infection

- see [Infectious Diseases, ID27](#)

Infectious Pediatric Exanthems

Table 19. Common Infectious Pediatric Exanthems

Disease	Pathogen(s)	Incubation Period	Communicability	Mode of Transmission	Rash	Associated Features	Management	Outcomes and Complications
Erythema Infectiosum (i.e. Fifth Disease/ Slapped Cheek)	Parvovirus B19	4-14 d	Low risk of transmission once symptomatic	Respiratory secretions or infected blood	Appearance: uniform, erythematous maculopapular 'lacy' rash Timing: 10-17 d after symptoms (immune response) Distribution: bilateral cheeks ('slapped cheeks') with circumoral sparing; may affect trunk and extremities	Initial 7-10 d of flu-like illness and fever Rash may be warm, non-tender, and pruritic Less common presentations include 'gloves and socks syndrome' or STAR complex (sore throat, arthritis, rash)	Supportive	Rash fades over days to week, but may reappear months later with sunlight, exercise Aplastic crisis
Gianotti-Crosti Syndrome (i.e. Papular Acrodermatitis)	EBV and Hep B (majority)	Variable	None	—	Appearance: asymptomatic symmetric papules Distribution: face, cheeks, extensor surfaces of the extremities, spares trunk	Viral prodrome May have lymphadenopathy and/or hepatosplenomegaly	Supportive Pain control	Resolves in 3-12 wk
Hand, Foot, and Mouth Disease	Coxsackie group A	3-5 d	Likely 1-7 d after symptoms but may be up to months	Direct and indirect contact with infected bodily fluids, fecal-oral	Appearance: vesicles and pustules on an erythematous base Distribution: acral. but may extend up the extremity	Enanthem: vesicles in the POSTERIOR oral cavity (pharynx, tongue)	Supportive	Mainly dehydration
Herpes Simplex	HSV 1,2	1-26 d		Direct contact, often through saliva for HSV-1 and sexual contact for HSV-2	Grouped vesicles on an erythematous base	Enanthem: vesicles/erosions in the ANTERIOR oral cavity (buccal mucosa, tongue) May present with herpetic whitlow (autoinoculation)	Mainly supportive Consider oral or topical antivirals	Local: secondary skin infections, keratitis, gingivostomatitis CNS: encephalitis Disseminated hepatitis, DIC Eczema herpeticum
Kawasaki Disease	See P87							
Measles	Morbillivirus	8-13 d	4 d before and after rash	Airborne	Appearance: erythematous maculopapular Timing: 3 d after start of symptoms Distribution: starts at hairline and spreads downwards with sparing of palms and soles	Prodrome of cough, coryza, conjunctivitis (3 Cs) Enanthem: Koplik's spots 1-2 d before rash Desquamation Positive serology for measles IgM	Infected: supportive Unimmunized contacts: measles vaccine within 72 h of exposure or IgG within 6 d of exposure Respiratory isolation, report to Public Health Prevention: MMR vaccine	Secondary bacterial infections: AOM, sinusitis, pneumonia Encephalitis Rare: myocarditis, pericarditis, thrombocytopenia, Stevens-Johnson syndrome, GN, subacute sclerosing panencephalitis

Table 19. Common Infectious Pediatric Exanthems (continued)

Disease	Pathogen(s)	Incubation Period	Communicability	Mode of Transmission	Rash	Associated Features	Management	Outcomes and Complications
Non-Specific Enteroviral Exanthems	Enteroviruses	Variable	Variable	Direct and indirect contact with infected bodily fluids	Polymorphous rash (macules, papules, vesicles, petechiae, urticaria)	Systemic involvement is rare, but possible	Supportive Diagnosis confirmed using viral cultures (NP and rectal swabs)	Self-limiting
Roseola	HHV 6	5-15 d	Unknown	—	Appearance: blanching, pink, maculopapular Timing: appears once fever subsides Distribution: starts at the neck and trunk and spreads to the face and extremities	High grade fever Common: irritability, anorexia, lymphadenopathy, erythematous TM and pharynx, Nagayama spots (erythematous papules on soft palate and uvula) Less common: cough, coryza, bulging fontanelles	Supportive	CNS: febrile seizures (10-25%), aseptic meningitis Thrombocytopenia
Rubella	Rubivirus	14-21 d	7 d before and after eruptions	Droplet	Appearance: pink, maculopapular Timing: 1-5 d after start of symptoms Distribution: starts on face and spreads to neck and trunk	Prodrome of low grade fever and occipital/retroauricular nodes STAR complex (sore throat, arthritis, rash) Positive serology for rubella IgM . Caution to pregnant women with exposure	Infected: supportive Prevention: MMR vaccine Report to Public Health	Excellent prognosis with acquired disease Arthritis may last days to weeks Encephalitis Irreversible defects in congenitally infected patients (i.e. congenital rubella syndrome)
Scarlet Fever	See P53							
Varicella	Varicella zoster virus	0-21 d	1-2 d pre-eruptions and 5 d post-eruption	Mainly airborne, but also through direct contact with vesicle fluid	Appearance: groups of skin lesions, polymorphic, from macules to papules to vesicles to crusts Timing: 1-3 d after start of symptoms Distribution: generalized	Significant pruritis Enanthem: vesicular lesions which may become pustular or ulcerate. Caution to pregnant women	Supportive Avoid salicylates (due to risk of Reye syndrome) Consider antivirals Respiratory and contact isolation, report to Public Health Prevention: varicella vaccine	Skin: bacterial suprainfection, necrotizing fasciitis CNS: acute encephalitis and cerebellar ataxia Systemic: hepatitis, DIC Congenital varicella syndrome if intrapartum infection

Infectious Mononucleosis

Definition

- systemic viral infection caused by EBV with multivisceral involvement; often called “the great imitator”

Epidemiology

- peak incidence between 15-19 yr old
- ~50% of children in developed countries have a primary EBV infection by 5 yr old, but <10% of children develop clinical infection

Etiology

- EBV: a member of herpesviridae
- transmission is mainly through infected saliva (“kissing disease”) and sexual activity (less commonly); incubation period of 1-2 mo

Risk Factors

- infectious contacts, sexually active, multiple sexual partners in the past

History

- prodrome: 2-3 d of malaise, anorexia
- infants and young children: often asymptomatic or mild disease
- older children and adolescents: malaise, fatigue, fever, sore throat, abdominal pain (often LUQ), headache, myalgia

Physical Exam

- classic triad: febrile, generalized non-tender lymphadenopathy, pharyngitis/tonsillitis (exudative)
- ± hepatosplenomegaly
- ± periorbital edema, ± rash (urticarial, maculopapular, or petechial) – more common after inappropriate treatment with β -lactam antibiotics
- any “-itis” (including arthritis, hepatitis, nephritis, myocarditis, meningitis, encephalitis, etc.)

Investigations

- heterophil antibody test (Monospot® test)
 - 85% sensitive in adults and older children, but only 50% sensitive if <4 yr of age
 - false positive results with HIV, SLE, lymphoma, rubella, parvovirus
- EBV titres
- CBC and differential, blood smear: reactive lymphocytes, lymphocytosis, Downey cells ± anemia ± thrombocytopenia
- throat culture to rule out streptococcal pharyngitis

Management

- supportive: adequate rest, hydration, saline gargles, and analgesics for sore throat
- splenic enlargement is often not clinically apparent so all patients should avoid contact sports for 6-8 wk
- if airway obstruction secondary to nodal and/or tonsillar enlargement is present (especially younger children), admit for steroid therapy
- acyclovir does NOT reduce duration of symptoms or result in earlier return to school/work

Prognosis

- most acute symptoms resolve in 1-2 wk, though fatigue may last for months
- short-term complications: splenic rupture, Guillain-Barré syndrome

Infectious Pharyngitis/Tonsillitis

Definition

- inflammation of the pharynx, especially the tonsils if present, causing a sore throat

Etiology

- viral (~80%): adenoviruses, enteroviruses, coxsackie, upper respiratory tract viruses, EBV, CMV
- bacterial (~20%): mainly GAS, *M. pneumoniae* (older children), *N. gonorrhoeae* (sexually active), *C. diphtheriae* (unvaccinated), *Fusobacterium necrophorum* (anaerobe causing Lemierre syndrome)
- fungal: *Candida*

Epidemiology

- season: GAS pharyngitis more common in late winter or early spring; viral all year long
- age: GAS pharyngitis peak incidence at 5-12 yr of age and uncommon <3 yr; viral pharyngitis affects all ages

History

- GAS: sore throat (may be severe), fever, malaise, headache, abdominal pain, N/V, absence of other URTI symptoms
- viral: sore throat (often mild), conjunctivitis, cough, rhinorrhea, hoarseness, diarrhea, flu-like symptoms (fever, malaise, myalgias)

Physical Exam

- GAS: febrile, pharyngeal/tonsillar erythema and exudates, enlarged (>1 cm) and tender anterior cervical lymph nodes, palatal petechiae, strawberry tongue, scarlatiniform rash
- viral: afebrile, absent/mild tonsillar exudates, minor and non-tender adenopathy, viral exanthems

Investigations

- no single sign or symptom reliably identifies GAS as the causative organism in children with sore throat
- scores are used to predict if throat culture will be positive (e.g. McIsaac Criteria)
 - these score systems have not been found to be sensitive or specific enough to diagnose GAS in children and adolescents with sore throat
- suspected diagnosis of GAS pharyngitis should be confirmed with a rapid streptococcal antigen test and a follow-up throat culture if the rapid test is negative

Management

- antibiotics (for GAS/*S. pyogenes*)
 - penicillin V or amoxicillin or erythromycin (if penicillin allergy) x 10 d
 - can prevent rheumatic fever if given within 9 d of symptoms; does NOT alter risk of post-streptococcal GN
- supportive: hydration and acetaminophen for discomfort due to pain and/or fever
- follow-up: if uncomplicated course, no follow-up or post-antibiotic throat cultures needed
- prophylaxis: consider tonsillectomy for proven, recurrent streptococcal tonsillitis

Complications

- preventable with antibiotics: AOM, sinusitis, cervical adenitis, mastoiditis, retropharyngeal/peritonsillar abscess, sepsis
- immune-mediated complications: scarlet fever, acute rheumatic fever, post-streptococcal GN, reactive arthritis, pediatric autoimmune neuropsychiatric disorder associated with group A streptococci (i.e. PANDAS)

SCARLET FEVER

- diffuse erythematous eruption
- delayed-type hypersensitivity reaction to pyrogenic exotoxin produced by GAS
- acute onset of fever, sore throat, strawberry tongue
- 24-48 h after pharyngitis, rash begins in the groin, axillae, neck, antecubital fossa; Pastia's lines may be accentuated in flexural areas
- within 24 h, sandpaper rash becomes generalized with perioral sparing, non-pruritic, non-painful, blanchable
- rash fades after 3-4 d, may be followed by desquamation
- treatment is penicillin, amoxicillin, or erythromycin x 10 d

RHEUMATIC FEVER

- inflammatory disease due to antibody cross-reactivity following GAS infection
- affects ~1:10,000 children in developed world; much more prevalent in developing nations; peak incidence at 5-15 yr of age
- mainly a clinical diagnosis based on Jones Criteria (revised)
 - requires 2 major OR 1 major and 2 minor PLUS evidence of preceding strep infection (history of scarlet fever, GAS pharyngitis culture, positive rapid Ag detection test, ASOTs)
- treatment: penicillin or erythromycin for acute course x 10 d, prednisone if severe carditis
- secondary prophylaxis with daily penicillin or erythromycin
- complications
 - acute: myocarditis, conduction system aberrations (sinus tachycardia, atrial fibrillation), valvulitis (acute MR), pericarditis
 - chronic: valvular heart disease (mitral and/or aortic insufficiency/stenosis), infectious endocarditis ± thromboembolic phenomenon
 - onset of symptoms usually after 10-20 yr latency from acute carditis of rheumatic fever

POST-STREPTOCOCCAL GLOMERULONEPHRITIS

- most common in children aged 4-8 yr old; M>F
- antigen-antibody mediated complement activation with diffuse, proliferative GN
- occurs 1-3 wk following initial GAS infection (skin or throat)
- clinical presentation varies from asymptomatic, microscopic and macroscopic hematuria (cola-coloured urine) to all features of nephritic syndrome (see *Nephritic Syndrome, P72*)
- diagnosis is confirmed with elevated serum antibody titres against streptococcal antigens (ASOT, anti-DNAse B), low serum complement (C3)
- management
 - symptomatic: fluid and sodium restrictions; loop diuretics for HTN and edema
 - in severe cases, may require dialysis if renal function significantly impaired
 - treat with penicillin or erythromycin if evidence of persistent GAS infection
- 95% of children recover completely within 1-2 wk; 5-10% have persistent hematuria

McIsaac Criteria (if >3 yr old)

HOT LACE

HOT – Fever >38°C
Lymphadenopathy (anterior cervical, tender)
OAge 3-14 yr
ANo Cough
CErythematous, exudative tonsils
ECMAJ 1998;158(1):75-83

Meningitis

Definition

- inflammation of the meninges surrounding the brain and spinal cord

Epidemiology

- peak age: 6-12 mo; 90% of cases occur in children <5 yr old

Etiology

- viral: enteroviruses, HSV
- bacterial: age-related variation in specific pathogens
- fungal and parasitic meningitis also possible
- most often due to hematogenous spread or direct extension from a contiguous site

Risk Factors

- unvaccinated
- immunocompromised: asplenia, DM, HIV, prematurity
- recent or current infections: AOM, sinusitis, orbital cellulitis
- neuroanatomical: congenital defects, dermal sinus, neurosurgery, cochlear implants, recent head trauma
- exposures: day care centres, household contact, recent travel

History

- signs and symptoms variable and dependent on age, duration of illness, and host response to infection
- infants: fever, lethargy, irritability, poor feeding, vomiting, diarrhea, respiratory distress, seizures
- children: fever, headache, photophobia, N/V, confusion, back/neck pain/stiffness, lethargy, irritability

Physical Exam

- infants: toxic, hypothermia, bulging anterior fontanelle, respiratory distress, apnea, petechial/purpuric rash, jaundice
- children: toxic, ↓ LOC, nuchal rigidity, Kernig's and Brudzinski's signs, focal neurologic findings, petechial/purpuric rash

Investigations

- blood work: CBC, electrolytes, Cr, BUN, glucose, C&S
- LP required for definitive diagnosis
 - Gram stain, bacterial C&S, WBC count and differential, RBC count, glucose, protein concentration
 - acid-fast stain if suspect TB
 - PCR for specific bacteria if available (helpful if already treated with antibiotics)
 - urinalysis and urine C&S in infants, Gram stain and culture of petechial/purpuric lesions
 - HSV and enterovirus PCR if suspected

Table 20. CSF Findings of Meningitis

Component	Normal Child	Normal Newborn	Bacterial Meningitis	Viral Meningitis	Herpes Meningitis
WBC (/μL)	0-6	0-30	>1,000 (cloudy, xanthochromic)	100-500*	10-1,000
Neutrophils (%)	0	2-3	>50	<40	<50
Glucose (mmol/L)	2.2-4.4	1.8-6.7	<1.66	>1.66	>1.66
Protein (mg/dL)	0.2-0.3	0.19-1.49	>1.0	0.50-1.0	>0.75
RBC (/μL)	0-2	0-2	0-10	0-2	10-50

*Lymphocytes predominate Modified from *Peds in Review* 1993;14:11-18 and *Ped Inf Dis J* 1996;15:298-303

Management

- supportive care
 - preservation of adequate cerebral perfusion by maintaining normal BP and managing ↑ ICP
 - close monitoring of fluids, electrolytes, glucose, acid-base disturbances, coagulopathies
- bacterial meningitis
 - if suspected or cannot be excluded, commence empiric antibiotic therapy while awaiting cultures or if LP contraindicated or delayed
 - isolation with appropriate infection control procedures until 24 h after culture-sensitive antibiotic therapy
 - fluid restrict if any concern for SIADH
 - hearing test
 - report to Public Health; prophylactic antibiotics for close contacts of Hib and *N. meningitidis* meningitis

Table 21. Antibiotic Management of Bacterial Meningitis

Age	Main Pathogens	Antibiotics
0 to 28 d	GBS, <i>E. coli</i> , <i>Listeria</i> Other: Gram-negative bacilli	Ampicillin + cefotaxime
28 to 90 d	Overlap of neonatal pathogens and those seen in older children	Cefotaxime + Vancomycin (+ Ampicillin if immunocompromised)
>90 d	<i>S. pneumoniae</i> , <i>N. meningitidis</i>	Ceftriaxone ± vancomycin If Penicillin allergic: Vancomycin + Rifampin

- viral meningitis
 - mainly supportive (except for HSV)
 - acyclovir for HSV meningitis
 - report to Public Health
- prophylaxis: appropriate vaccinations significantly decrease incidence of bacterial meningitis (see *Routine Immunization, P4*)

Complications

- mortality: neonate 15-20%, children 4-8%; pneumococcus > meningococcus > Hib
- acute: SIADH, subdural effusion/empyema, brain abscess, disseminated infection (osteomyelitis, septic arthritis, abscess), shock/DIC
- chronic: hearing loss, neuromotor/cognitive delay, learning disabilities, neurological deficit, seizure disorder, hydrocephalus

**Signs of Meningismus**

BONK on the head
 Brudzinski's sign
 Opisthotonos*
 Nuchal rigidity
 Kernig's sign

*Opisthotonos: rigid spasm of the body, with the back fully arched and the heels and head bent back

Mumps

Definition

- acute, self-limited viral infection that is most commonly characterized by adenitis and swelling of the parotid glands

Epidemiology

- incidence in Ontario has declined since introduction of two-dose MMR vaccination schedule
- average of 25 reported cases per yr
- majority of reported cases in children between 5-10 yr of age

Etiology

- mumps virus (RNA virus of the genus *Rubulavirus* in the *Paramyxoviridae* family)
- transmission via respiratory droplets, direct contact, fomites
- incubation period: 14-25 d
- infectivity period: 7 d pre-parotitis to 5 d post-parotitis
- upper respiratory tract lymph nodes salivary glands, gonads, pancreas, meninges, kidney, heart, thyroid

History

- non-specific prodrome of fever, headache, malaise, myalgias (especially neck pain)
- usually followed within 48 h by parotid swelling secondary to parotitis (bilateral, preauricular, ear pushed up and out)
- parotid gland is tender and pain worsened with spicy or sour foods
- one third of infections do not cause clinically apparent salivary gland swelling and may simply present as an URTI

Investigations

- clinical diagnosis, but may be confirmed with IgM positive serology within 4 wk of acute infection
 - may also use PCR or viral cultures from oral secretions, urine, blood, and CSF
 - blood work: CBC (leukopenia with relative lymphocytosis), serum amylase (elevated)

Management

- mainly supportive: analgesics, antipyretics, warm or cold packs to parotid may be soothing
- admit to hospital if serious complications (meningitis, pancreatitis)
- droplet precautions recommended until 5 d after onset of parotid swelling
- prophylaxis: routine vaccination (see *Routine Immunization, P4*)

Complications

- common: aseptic meningitis, orchitis/oophoritis
- less common: encephalitis, pancreatitis, thyroiditis, myocarditis, arthritis, GN, ocular complications, hearing impairment

Pertussis

Definition

- prolonged respiratory illness characterized by paroxysmal coughing and inspiratory “whoop”

Epidemiology

- ~10 million children <1 yr old affected worldwide, causes up to 400,000 deaths/yr
- greatest incidence among children <1 yr (not fully immunized) and adolescents (waning immunity)

Etiology

- *Bordetella pertussis*: Gram negative pleomorphic rod
- highly contagious; transmitted via respiratory droplets released during intense coughing
- incubation period: 6-20 d; most contagious during catarrhal phase but may remain contagious for weeks after

History

- prodromal catarrhal stage
 - lasts 1-7 d; URTI symptoms (coryza, mild cough, sneezing) with NO or LOW-GRADE fever
- paroxysmal stage
 - lasts 4-6 wk; characterized by paroxysms of cough (“100 day cough”), sometimes followed by inspiratory whoop (“whooping cough”)
 - infants <6 mo may present with post-tussive apnea, whoop is often absent
 - onset of attacks precipitated by yawning, sneezing, eating, physical exertion
 - ± post-tussive emesis, may become cyanotic before whoop
 - vomiting after whooping episodes
- convalescent stage
 - lasts 1-2 wk; characterized by occasional paroxysms of cough, but decreased frequency and severity
 - non-infectious but cough may last up to 6 mo

Investigations

- NP specimen using aspirate or NP swab
 - gold standard: culture using special media (Regan-Lowe agar)
 - PCR to detect pertussis antigens
- blood work: CBC (lymphocytosis) and serology (antibodies against *B. pertussis*)

Management

- admit if paroxysms of cough are associated with cyanosis and/or apnea and give O₂
- supportive care
- antimicrobial therapy indicated if *B. pertussis* isolated, or symptoms present for <21 d
 - use macrolide antibiotics (azithromycin, erythromycin, or clarithromycin)
- droplet isolation until 5 d of treatment and report to Public Health
- prophylaxis
 - macrolide antibiotics for all household contacts
 - prevention with vaccination in infants and children (Pentacel®), and booster in adolescents (Adacel®) (see *Routine Immunization, P4*)

Complications

- pressure-related from paroxysms: subconjunctival hemorrhage, rectal prolapse, hernias, epistaxis
- respiratory: sinusitis, pneumonia, aspiration, atelectasis, pneumomediastinum, pneumothorax, alveolar rupture
- neurological: seizures (~3%), encephalopathy, ICH
- mortality: ~0.3%; highest risk in infants <6 mo old

Pneumonia

- see *Respirology, P80*

Periorbital (Preseptal) and Orbital Cellulitis

- see *Ophthalmology, OP9*

Sexually Transmitted Infections

- see *Family Medicine, FM42* and *Gynecology, GY27*

Cardinal Signs of Orbital Cellulitis

- Ophthalmoplegia/diplopia
- Decreased visual acuity
- Pain with extraocular eye movement

Sinusitis

- see [Family Medicine, FM43](#)
- complication of $\leq 10\%$ of URIs in children
- clinical diagnosis
- diagnostic imaging is NOT required to confirm diagnosis in children
 - routine CT not recommended, but consider if suspect complications of sinusitis, persistent/recurrent disease, need for surgery
- antibiotic therapy for all children (although nearly half resolve spontaneously within 4 wk)
- complications: preseptal/orbital (preseptal/orbital cellulitis, orbital abscess, osteomyelitis, etc.), intracranial (meningitis, abscess, etc.), Pott's Puffy tumour

Urinary Tract Infection

Definition

- infection of the urinary bladder (cystitis) and/or kidneys (pyelonephritis)

Epidemiology

- overall prevalence in infants and young children presenting with fever is 7%
- <4-6 wk old: more common in boys
- >1 yr old: females have two- to four-fold higher prevalence

Etiology

- majority (>95%) have a single cause (~70% *E. coli*)
- Gram-negative bacilli: *E. coli*, *Klebsiella*, *Proteus*, *Enterobacter*, *Pseudomonas*
- Gram-positive cocci: *S. saprophyticus*, *Enterococcus*

Risk Factors

- non-modifiable: female gender, Caucasian, previous UTIs, family history
- modifiable: urinary tract abnormalities (VUR, neurogenic bladder, obstructive uropathy, posterior urethral valve), dysfunctional voiding, repeated bladder catheterization, uncircumcised males, labial adhesions, sexually active, constipation, toilet training

History

- infants and young child: often just fever or non-specific symptoms (poor feeding, irritability, FTT, jaundice if <28 d old, vomiting)
- older child: fever, urinary symptoms (dysuria, urgency, frequency, incontinence, hematuria), abdominal, and/or flank pain

Physical Exam

- infants and young child: toxic vs. non-toxic, febrile, FTT, jaundice; look for external genitalia abnormalities (phimosis, labial adhesions) and lower back signs of occult myelodysplasia (e.g. hair tufts), which may be associated with neurogenic bladder
- older child: febrile, suprapubic and/or CVA tenderness, abdominal mass (enlarged bladder or kidney); may present with short stature, FTT, or HTN secondary to renal scarring from previously unrecognized or recurrent UTIs

Investigations

- sterile urine specimen
 - clean catch, catheterization, suprapubic aspiration or 'Tap and Rub' technique
 - urinalysis (leukocyte esterase, nitrites, erythrocytes, hemoglobin), microscopy (bacteria and leukocytes, erythrocytes), C&S
- diagnosis established if urinalysis suggests infection AND if $\geq 50,000$ colony-forming units per mL of a uropathogen cultured

Management

- admit if: <2 mo old, urosepsis, persistent vomiting, inability to tolerate oral medication, moderate-severe dehydration, immunocompromised, complex urologic pathology, inadequate follow-up, failure to respond to outpatient therapy
- supportive care: maintenance of hydration and adequate pain control
- antibiotics
 - base on local antimicrobial susceptibility patterns
 - commence broad empiric therapy until results of urine C&S known, and then tailor as appropriate
 - neonates: IV ampicillin and gentamicin
 - infants and older children: oral antibiotics (based on local *E. coli* sensitivity) if outpatient; IV ampicillin and gentamicin if inpatient
 - duration 7-10 d
- imaging
 - renal and bladder U/S for all febrile infants (<2 yr) with UTIs looking for anatomical abnormalities, hydronephrosis, abscess
 - VUCG not recommended after 1st febrile UTI unless U/S reveals hydronephrosis, obstructive uropathies or other signs suggestive of high-grade VUR

Features Suggestive of Pyelonephritis

- High-grade fever
- Flank or high abdominal pain
- CVA tenderness on palpation

Bagged urine specimen not useful for ruling in UTI (high false positive rate > 85%), but useful for ruling out UTI (high sensitivity)

Prophylaxis After First Febrile Urinary Tract Infection in Children? A Multicentre, Randomized Controlled, Noninferiority Trial

Pediatrics 2008;122:1064-1071

Study: Randomized, controlled, open-label, 2 armed, noninferiority trial.

Patients: 338 patients aged 2 mo to <7 yr who had a first episode of febrile UTI.

Intervention: No prophylaxis vs. prophylaxis.

Outcome: Recurrence rate of febrile UTI and rate of renal scarring.

Results: No significant difference in recurrence rate or in the rate of renal scarring between the prophylaxis and no prophylaxis group.

- follow-up: outpatients to return in 24-48 h if no clinical response and seek prompt medical evaluation for future febrile illnesses
- prophylaxis: generally not recommended unless higher grades of VUR

Complications

- long-term morbidity: focal renal scarring develops in 8% of patients; long-term significance unknown

Neonatology

Gestational Age and Size

Definitions

- classification by GA
 - preterm: <37 wk
 - near-term: 35-37 wk
 - term: 37-42 wk
 - post-term: >42 wk
- classification by birth weight
 - SGA: 2 SD < mean weight for GA or <10th percentile
 - AGA: within 2 SD of mean weight for GA
 - LGA: 2 SD > mean weight for GA or >90th percentile

Table 22. Abnormalities of Gestational Age and Size

Features	Causes	Problems
Pre-Term Infants <37 wk	Spontaneous: cause unknown Maternal disease: HTN, DM, cardiac and renal disorders Fetal conditions: multiple pregnancy, congenital abnormalities, macrosomia, red blood cell isoimmunization, fetal infection Pregnancy issues: placental insufficiency, placenta previa, uterine malformations, previous preterm birth, infection, placental abruption Behavioural and psychological contributors: smoking, EtOH, drug use, psychosocial stressors Sociodemographic factors: age, socioeconomic conditions	RDS, apnea of prematurity, chronic lung disease, bronchopulmonary dysplasia Feeding difficulties, NEC Hypocalcemia, hypoglycemia, hypothermia Anemia, jaundice Retinopathy of prematurity ICH/IVH PDA
Post-Term Infants >42 wk Leathery skin Meconium staining	Most cases unknown Increased in first pregnancies Previous post-term birth Genetic factors	Increased risk of stillbirth or neonatal death Increased birthweight Fetal "postmaturity syndrome": impaired growth due to placental dysfunction Meconium aspiration
SGA Infants <10th percentile Asymmetric (head-sparing): late onset, growth arrest	Extrinsic causes: placental insufficiency, poor nutrition, HTN, multiple pregnancies, drugs, EtOH, smoking	Perinatal hypoxia Hypoglycemia, hypocalcemia, hypothermia, hyperviscosity (polycythemia), jaundice, hypomotility
Symmetric: early onset, lower growth	Intrinsic causes: maternal infections (TORCH), congenital abnormalities, syndromal, idiopathic	PDA
